SUPPLEMENT TO "THE ELECTRICIAN," NOVEMBER 4, 1887.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME XIX.

FROM MAY 13, 1887, TO NOVEMBER 4, 1887.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1887.

Digitized by Google

INDEX TO VOL. XIX.

A

Accumulators (*see* BATTERIES, SECONDARY).
Alcoholic Solutions of Metallic Salts, Electrolysis of, by G. Gore, 486.
Alloys, Electro-Deposition of, by S. P. Thompson, 186.
Alternating Current Phenomena, by E. Thompson, 104.
Alternating Currents, Distribution by, by Slattery, 446.
American Cousins, Our (Leading Article), 120.
American Electric Light Association, 446, 465.
American Institute of Electrical Engineers (Leading Article), 120.
American National Telephone Exchange Association, 475, 524.
Ammeters, with Permanent Magnets, by Profs. Ayrton and Perry, 172.
Ampere-Balance (Centi or Deci) applied to Measuring E.M.F. of a Single Cell, by Sir W. Thomson, 401.
Ampere-Balances, Sir W. Thomson's New, 402.
Anglo-American Brush Company *v.* Crompton, 43.
Appointments, Official, Ethics of (Leading Article), 198.
Arc Lamp, Hardt's, 133
Arc Lamp, Lever's, 503.
Armstrong, H. E., Reply to Lodge's Comparison of his and Arrhenius's Views on Electrolysis, 330.
Arrhenius and Armstrong's Views on Electrolysis, Comparison of, by O. J. Lodge, 268, 330.
Arrhenius, S., Conductivity, &c., of Electrolytes, 213, 277, 299, 323, 342.
Arts, Society of (*see* SOCIETIES' MEETINGS).
Australian Telegraphy, and the Eastern Company, 11, 32, 55.
Ayrton and Perry, Profs., Papers by :—
  Driving Dynamos with Short Belts, 187.
  Magnetic Resistance, 172.
  Measuring the Coefficients of Self-Induction, 17, 39, 58, 83.
  Permanent Magnet Ammeters, &c., 172.

B

Balances, Electric, Sir W. Thomson's New, 402.
Bardonnaut's Sourdines, 538.
Barrett, W. F., Physical Properties of Manganese Steel, 544.
Batteries, Primary :—
  Newton's, 126.
  Tungstic Acid for, 394.
Batteries, Secondary :—
  Bailly's, by K. Hedges, 485.
  for Locomotion, by A. Reckenzaun, 426.
  in Practice, by E. P. Roberts, 128.
  Smith's Cell, 210.
  for Tramways, 170.
  Union Company's Cell, 209.
Beresford, Major C. F., Field Telegraphy, 64.
Bidwell, S., Magnetic Torsion of Iron Wires, 87.
Books, Reviews of (*see* REVIEWS).
Bottomley, J. T., Radiation, 359.
Brakes, Electric, Tests of, 223.
British Association (*see* SOCIETIES' MEETINGS).
British Museum, Lighting of, 345.
Brussels 1888 Exhibition, 275.

C

Cable Companies, Statistics of, by L. Wells, 132.
Cable, Localisation of Complete Fracture of, by A. E. Kennelly, 480, 499.
Canadian Pacific Cable Route, 32, 55.
Capacities, Comparison of, by E. C. Rimington, 172.
Cardew, Capt. P., Tests of Gaulard and Gibbs' Transformer, 185.
Cardew's Voltmeter, Improved Form, 270.
Central Station Construction, by J. A. Powers, 150.
Chattick, A. P., Magnetic Potentiometer, 43.
Chauvin, Von, *v.* Anderson and Others, 109.
Cherrill, N. K., Telephonic Investigations, 138.
China Switches, 465.
Chubb's Safe Alarm, 167.
City and Guild's Institute Report (Leading Article), 356.
City and Guilds Institute, Summer Lectures at, 161.
City Notes, 22, 44, 66, 88, 110, 132, 152, 174, 194, 216, 236, 261, 282, 303, 324, 346, 366, 386, 428, 447, 468, 488, 508, 528, 548.
Clarke's Telemeter System, 403.

COMPANIES' MEETINGS, REPORTS, &c.:—
  Anglo-American Brush, 236.
  Anglo-American Telegraph, 235, 257.
  Australasian Electric Light, 505.
  Brazilian Submarine, 21, 528, 547.
  Consolidated Telephone, 65, 87, 152.
  Cuba Submarine, 216, 235, 259.
  Direct Spanish Telegraph, 427, 467.
  Direct United States Cable, 235, 280.
  Eastern Extension Telegraph, 508, 526.
  Eastern Telegraph, 132, 215, 232.
  Edison and Swan United, 282, 302.
  Faure Accumulator, 216.
  Globe Telegraph and Trust, 236, 259.
  Hammond, 527.
  India Rubber, &c., 235.
  Lancashire and Cheshire Telephone, 345, 366.
  London Platino-Brazilian Telegraph, 44, 65.
  Manchester Edison, 386.
  National Telephone, 260, 301.
  Northern District Telephone, 132.
  South of England Telephone, 152, 172, 216.
  Submarine Cables Trust, 21.
  Submarine Telegraph, 236, 256.
  Telegraph Construction and Maintenance, 234.
  United Telephone, 174, 191.
  Water Primary Battery, 507.
  West India and Panama Telegraph, 22, 43.
  Woodhouse and Rawson, 260, 282, 548.

Companies, New, 236, 261, 282, 386.
Conductivity, &c., of Electrolytes, by S. Arrhenius, 213, 277, 299, 323, 342.
Conductivity of Salts under Pressure, 333.
Conductors, Forbes's Tables for Calculating Size of, 520.
Conduit for Electric Railway, Bidwell's, 298.
Contacts, Electrical, Method of Reinforcing, by E. W. Serrell, jun., 435.
Copper Wire, by W. H. Preece, 372.

Correspondence :—

Alternating Currents, Distribution by, 438.
Arc Light Projectors in the Navy, 358.
Australasian Telegraphy and the Eastern Company, 33.
Batteries, Primary :—
  D'Humy's, 377, 394, 418.
  Newton's, 144.
  Packing for Shipment, 228.
  Wanted for Lighting, 438.
Batteries, Secondary :—
  Theory of, 7, 33.
  Use of Minium in, 34, 79.
  Wilson's Automatic Switch for, 99, 121.
Bidwell Electric Railway Conduit, 316.
Cardew's Voltmeter, 8, 182.
Carswell, T. P., Train Lighting at Glasgow, 397.
Cherrill, N. K., Incandescent Lamp Manufacture, 8, 414.
Davy, Edward, 99, 121.
Distribution by Alternating Currents, 438.
Donovan, H. C., Long Distance Telephony, 8.
Drexler, F., Measuring Magnetic Induction, 254.

CORRESPONDENCE *(continued)* :
Dynamos :—
  Admiralty Specification for, 182.
  Construction of, 34.
  Forbes's Non-polar, 159, 181, 205, 225, 227, 253, 273, 293, 312, 315, 335, 357, 397.
  Formulæ for Self-regulating, 397, 415, 437.
  Menges' Method of Regulating, 337.
  Oerlikon Machine, 315.
  Resistance of Air-space, 519.
  Sparking at the Fly-wheel, 9, 35, 55.
Eastern Telegraph Company and Australasian Telegraphs, 33.
Electric Equivalence, 7, 33, 52.
Electric Lighting :—
  on Glasgow Underground Railway, 78, 93, 397.
  on the ss. "Hyæna," 101, 121.
  in India, 53.
  Rules, Proposed New, 394, 418.
  in Switzerland, 160.
  Tenders, 53, 78, 99, 144, 159, 205, 224, 274.
  in Theatres, 459.
  in Turin (Gaulard-Gibbs System), 34, 78, 100.
  in Waterford, 505.
Electric Traction, 520.
Electrical Engineers, Proposed Association of, 458, 477, 498, 518, 540.
Electricity, What is It? 458.
Electro-Deposition, Watt's Book on, 316.
Esson, W. B., Admiralty Dynamos, 182.
Esson, W. B., Formulæ for Self-Regulating Dynamos, 437.
Fahie, J. J., Edward Davy and Wilson's Accumulator Switch, 99.
Faults, Variation of Resistance of, 145.
Forbes's Non Polar Dynamo, 159, 181, 205, 225, 227, 253, 273, 293, 312, 315, 335, 357, 397.
Force, Supposed New, 337, 358.
Hatton, H. Finch, Telegraph Tariffs, the Pacific Company's Propositions, 33.
Heaviside, O., Nomenclature, Magnetic Resistance, &c., 143, 183.
Hedges, K., Train Lighting at Glasgow, 397.
Incandescent Lamps :—
  Manufacture of, 414.
  Varnished, 8.
Jablochkoff's Transformer Patent, 417.
Jubilee Beacon Lights, 205.
Kennedy, R., Distribution by Alternating Currents, 428.
Kennedy, R., Regulation of Series Transformers, 100.
Magnetic Induction, Measurement of, 254.
Magnetic Resistance, 143.
Magnetism and Gravitation, 101.
Menges' Method of Regulating Dynamos, 337.
Meter, Jehl and Rupp's, 457.
Naturalists and the Electric Light, 101, 121.
Nevile, R. H. C., Electrical Phenomena-Sparking at Dynamo Fly-Wheel, 35.
Newcastle Exhibition, Arc Lamps at, 121.
Nomenclature, 143, 161, 182.
Oerlikon Dynamo, 315.
Opera Comique, Fire at, 79.
Pacific Telegraph Company's Propositions, 33.
Paraffin Wax as an Insulator, 254.
Pardoe, G. Z., Construction of Dynamos, 34.
Perry, John, Springs on Telegraph Wires, 437.
Phillips, S. E., Volts and Calories, 35.
Radiation as Affecting Lamp Filaments, 377, 395.
Railway Conduit, Electric, Bidwell's, 316.
Rules for Installations, Proposed New, 394, 418.
Sayers, H. M., Telephonic Investigations, 159.
Scattergood, B. P., Non-Polar Dynamos, 181, 273.
Sharp and Kent, Regulation of Series Transformers, 121.
Smith, M. H., Bidwell's Railway Conduit, 316.
Snowdon, R., Forbes's Non-Polar Dynamo, 159, 225, 254, 293, 335, 358, 397.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. XIX. FRIDAY, MAY 13, 1887. Price 4d.

NOTES.

Hamburg.—The German Government are constructing a special line exclusively for the telephone between Hamburg and Kiel.

Poland.—The Russian Government is said to be taking steps to connect the whole of the fortresses in Russian Poland by means of subterranean lines.

Geneva.—An electric tramway is projected between Geneva and the little town of Coppet. A concession will shortly be granted to an electric lighting company guaranteeing them a monopoly in Geneva for nine years.

The French Academy.—We regret to announce the death of M. Gosselin, the President of the French Academy. M. Gosselin was a member of the section of Medicine and Surgery, in which departments he had attained a high scientific fame.

Royal Institution.—The following are the titles of the lectures delivered by Prof. W. E. Ayrton, F.R.S., on April 26, May 3, and May 10:—"The Cost of Electricity," "Apparent Momentum of Electricity Produced by Magnetic Inertia," "Self and Mutual Induction, and their Bearing on the Question of the Economic Distribution of Electrical Energy."

The Royal Institution.—The Chair of Natural Philosophy at the Royal Institution, vacant by the resignation of Prof. Tyndall, has been accepted by Lord Rayleigh. The title of Honorary Professor of Natural Philosophy has been conferred by the Institution on Prof. Tyndall. The appointment of Lord Rayleigh will be received with satisfaction by the whole scientific world, and is especially gratifying to electricians.

Vienna.—Messrs. Getz and Odendall have recently obtained orders for some batteries of their largest sized accumulators of the Farbaky-Schneck type. The firm of Kremenetzky and Mayer (the Brush Company) also talk of manufacturing accumulators of the E.P.S. type in Vienna. It will be interesting to see what may be done by either of the above firms as regards the question of patents if the latter proposal of the Brush Company is carried out.

A Remarkable Motor.—We have been favoured with the following description of an electromotor, which we reproduce as received:—"It is of recent type, double-armoured armature, working on 30 amperes and 100 volts, and containing compensating cylinders and elaborate cut-outs for the very varying pressure required. The nicety of finish remarkable in this machine enables it to produce at least 15,000 ohms, and being driven at 150lb. to the square inch gives out 95 per cent. of the initial energy. A very difficult problem is evidently nearer solution, as our electricians will see."

The Caoutchouc Species.—Mr. Bruce Warren, recently lecturing before the Society of Arts, stated that the sap of the *Syphonia elastica* (a plant indigenous to the climate of Para) frequently contains free ammonia. He attributed this fact to the silent discharges of atmospheric electricity, which take place at night from the branches of the trees and are easily observed. Other plants of the same order as the *Masaraudubæ* (cow tree) and the *Mangabeira* (mango tree) do not develop free ammonia in their sap under the same conditions. He thought that the two latter trees could be introduced with advantage into many of our colonies.

The Society of Arts.—The Society of Arts have recently laid down an Immisch series-wound electric motor for lecture and general purposes. The machine is of the well-known Immisch type. The field connections are arranged so that the coils can be coupled in series or parallel. This arrangement is necessitated by the variety of work which the motor has to do. The maximum output is 3 brake horse-power at 950 revolutions per minute. The E.M.F. required is 110 volts, and so the motor can be run in parallel with the incandescent lamps used to light the large hall. It is found to be a valuable addition to the society's plant, and enables many lectures to be illustrated in a very practical way.

Antwerp.—Some time ago M. Nothomb succeeded in launching a company for supplying the City of Antwerp with electric light. This new undertaking was, however, immediately attacked by the gas company, who claimed to possess the exclusive right to light the town until the year of grace 1912. The action has been carried from court to court, but the final Court of Appeal at Brussels has now decided in favour of the claims of the gas company. The commiseration of the whole civilised world—even of London itself—may well be extended to this unfortunate city, doomed without hope of release, except from the goodwill of the company, to see by gas flames for another quarter of a century.

The Latest Accumulator.—For all purposes where accumulators have to be carried about, for tramcars, and, above all, for miners' lamps, this battery will prove—if only the claims of the inventors be verified—to be absolutely without a rival; its name should at least be the *Sans Pareil*, or even the *Ne Plus Ultra*. Our enthusiasm will be appreciated when we state—on the authority of the inventors H.H. Haefner and Langhans—that the E.M.F. of a single couple amounts to as much as 3·2 volts. Henceforth, a lamp of 12 candles may be maintained alight at full power for the space of three hours by means of a battery measuring 1 cubic decimetre—so at least we are told. The negative plate of this cell is formed of a mixture of peroxide of manganese and protoxide of lead. The positive plate consists of an amalgam of "the heavy metals." (? An, Pt, Ir, Os, &c.) The solution is alkaline.

Lighting at Vienna.—The Imperial Continental Gas Association have now obtained the permission for laying their

Digitized by Google

cables between the Central Station Schenkenstrasse, No. 10, and the Opera House and new Burg Theatre. Several of the very objectionable clauses in the conditions, which were previously proposed and to which we have referred, have been either altogether omitted or much modified in the accepted agreement between the Imperial Continental Gas Association and the Geminderath, although the exceedingly high yearly tax is still imposed. The cables are to be supplied by Messrs. Chaudior and Co., who are manufacturing in Vienna, under the patents of Berthoud-Borel ; a high insulation resistance has been specified. The Opera House will probably now be closed for a month during the summer to allow of the final alterations to light fittings, &c., and will be reopened about August 1. The building of the new Burg Theatre will not be completed until some time in 1888, so that it will be electrically lighted from the commencement of its career.

Determining the Flashing Point of Mineral Oils by Electricity.—The "flashing point" of a mineral oil is the temperature at which the liquid begins to give off inflammable vapours. In America, this point is determined by a simple electrical method known under the name of the Seybolt process. The mineral oil is placed in a vessel, open at the top, and heated by means of a water-bath. A thermometer stands in the oil, and a pair of electrodes at a fixed distance apart hang just over the surface of the liquid. By means of a small induction coil a spark is passed between the electrodes, and the temperature of the water bath being gradually increased, the reading of the thermometer is taken at the instant that the vapour takes fire. It is, however, said that this method does not yield very concordant results, and as the industry is in America one of enormous importance, it would probably be worth while to devise some improvements in carrying out the details ; it is probably difficult to get an accurate reading of the thermometer with the present arrangements.

Secondary Battery Questions in Belgium.—A correspondent at Brussels writes as follows :—The employment of accumulators is on the increase in this country, although unhappily the industry is hampered by the number of various "systems" now in competition, and by the eternal question as to the right to the use of red lead applied mechanically. Thus, at Brussels, M. Julien, who is the managing director of the Cie l'Electrique, makes use by turns of his personal claims for the metallic composition of the supports (lead-antimony-mercury) and of those of his company for the combination of a support and of material supported. Nevertheless, the use of oxide of lead is certainly open to the public, since it has been shown that M. Planté had employed this method in the course of his researches long before M. Faure had dreamt of his patent. So that at best M. Faure could only claim the method of attaching and retaining his red lead—which no one now envies him. Yet it is by means in this direction periodically renewed that it is sought to shut the public out of the free use of Planté's discoveries. It is probable, however, that the game will prove an unprofitable one in the long run.

Preservation of Wooden Poles.—A simple method of treating wood with preservative solutions is employed in Norway for telegraph poles. After the poles are set in place a man goes from one to another with an augur, with which he bores a hole in each post, beginning at a point about 2ft. above the ground, and boring obliquely downward, at as small an angle as possible, with the axis of the post, until the point of of the augur reaches the centre of the stick. The auger-hole should be an inch in diameter, and, in telegraph poles of the ordinary size, will hold easily 4 to 5 ounces of sulphate of copper, which is put into it in the form of coarsely powdered crystals, and the opening then stopped with a plug, the end of which is left projecting as a handle, so that it can be pulled out and replaced. Just what action it may be that then goes on in the interior of the stick no one pretends to say ; but it is found that the crystals of copper sulphate disappear slowly, so that every three or four months the charge must be renewed ; while the wood, both above and below the auger-hole, even to the very top of the pole, gradually assumes the greenish tint due to the presence of copper in the pores.

Electric Lighting on Board Forth Passenger Steamers. On Saturday, May 7th, a large company of gentlemen met, being invited by Mr. M. P. Galloway, Leith, to witness the official trials of the installations fitted on board the ss. "Lord Morton" and "Edinburgh Castle" by Mr. Rankin Kennedy, of Glasgow. The dynamos are of Kennedy's new ironclad type, and are run at a speed of 800 revolutions per minute, driven by "Archer" engines from the fly-wheels with Dick's patent gutta percha and canvas belts. The "Lord Morton" has 35 and the "Edinburgh Castle" thirty 20 candle-power Swan lamps. The fittings in saloons and cabins are silver-plated, of a neat design, with cut glass globes. Each fitting has a switch, so that the light can be turned off and on at will. Each steamer has a deck lantern (portable) with five 20 candle-power lamps to be used in landing and embarking passengers and luggage at the various piers at night. The installations have been fitted up under the superintendence of Mr. James Campbell, of Mr. Kennedy's firm. After various tests, the results obtained were to the entire satisfaction of Mr. R. Young, the superintendent-engineer, and Mr. Galloway, the owner, who have two other steamers being fitted up by Mr. Kennedy in a similar manner.

Earthquake Speculations.—The origin of earthquakes has been the subject of much speculation and many theories, not a few of which have included the factor of electricity as a prominent cause. Recently again Ch. Naudin, in *Comptes Rendus*, suggests that earthquakes may be due to the greater or less resistance which certain parts of the earth's crust present to the electric currents generated within the globe. He points out further, or asserts, that the countries visited by earthquakes are devoid of forests, which would favour the escape of the electricity. In a somewhat similar manner Mr. George O'Brien, writing in the American *Mining Journal*, distinguishes most of the earthquakes that occur on the western coast of South America as arising from the local action and volcanic exhalations in the Andes causing electrical currents down the valleys from east to west, and under the "made ground," which is derived from constant wearing down of the mountains. "The electric current travelling on the firm rock, conducted by the moisture and water lying upon it, and thus in contact with the material possessing for it the greatest powers of conductivity, and from such fulcrum and firm basis the current shakes the made ground above it, with buildings thereon, the electric fluid then escaping into the atmosphere, animating all nature and eventually causing when in excess thunder and lightning." The latter "theory" is somewhat involved, but the idea embodied in both those cited appears to be that the variable electrical tension in different parts of the earth's crust creates a condition which, under certain circumstances, causes a stress sufficient to overcome the normal state of equilibrium. As to the point about the absence of forest, that seems open to question. The West Indian Islands and South American regions subject to earthquake are generally, and in some cases superabundantly, provided with trees.—*Electrical World.*

EXPERIMENTS WITH HIGH-TENSION ELECTRICITY.—It is well known that by means of a suitable commutator, driven by clockwork or otherwise, and connected with a condenser, the plates of which are alternately charged in parallel and discharged in series, a very high tension may be attained with only a single battery cell as the original source of electricity. The apparatus is, however, more expensive, and even more likely to suffer damage than the modern forms of static induction machines, so that it is very seldom employed in this country. In France, however, the rheo-static machine has always received more favour, and an account of a series of experiments, some of which at least are new to us, carried out with one of these machines, appeared recently in our contemporary *Electricité*. One advantage of the rheostatic machine is that the E.M.F. between the discharging points can be closely calculated if we simply know the E.M.F. of the source, the capacity of each pair of plates, and the number of pairs of plates in the condenser. However, no estimate as to the E.M.F. required for the following experiments is found in the paper. Let a small glass beaker be filled with salt water, and into this dip a platinum wire connected with one electrode. Take a capillary tube open at both ends, pass a platinum wire through it connected with the second electrode, and dip the tube and wire under the surface of the liquid. In all these experiments, if a static induction machine be employed, the circuit must be continually made and broken elsewhere either in shunt or series; then, on setting up the interrupted difference of potential, a brilliant spark is seen at the lower extremity of the tube, and the liquid rises a little at each discharge, attaining a height of 0·25m. to 0·30m. The action is just like that of an hydraulic ram. If the height of the tube be less than that to which the liquid could attain naturally it overflows at top, but in doing so the drops pass out of the circuit and therefore again break forth into flashes and gleams of fire. In the dark the experiment is a very effective one. Next let the beaker be exchanged for an open dish, and take a very short piece of tubing, say about an inch in length. Then on arranging everything else as before, taking care, however, that the tube dips about half its length under water and that the platinum wire passes *very nearly* right through it, on starting the discharge a fine jet of water is thrown up to the height of about a metre. The noise made by the sparks in this experiment is extremely loud, and the concussions are so violent that the glass vessel is sometimes broken. The experiment is more successful if the wire which enters the liquid without passing through the tube be insulated, except at its extremity. If this be not done a good deal of water is scattered about. This wire should also be the positive pole. If it is made negative the jet is scarcely half as high. A brilliant flaming discharge, giving deafening explosions, may be obtained by allowing the platinum wire to enter at the lower end of a rather short capillary tube (still under water), and to pass nearly to the top; then let the other electrode be brought over the top of the tube. It seems probable that this flame is in part due to the separation and recombination of the elements of water.

HISTORY OF THE SIMULTANEOUS TRANSMISSION OF MESSAGES BY ONE LINE WIRE.—The recent issue of the *Journal* of the Society of Telegraph-Engineers contains the following abstract of an article which appeared in *La Lumière Electrique*, October 23rd, 1886:—"In an English patent, No. 12,959, of the 7th February, 1850, Highton points out the possibility of using ordinary battery currents for working the instruments, whilst currents from electro-magnetic generators might be used for actuating sounders. Werner Siemens, in 1856, proposed the simultaneous sending of ordinary battery currents, and of alternate currents produced by a magneto-inductor, over the same wire. The ordinary currents would act on any electro-magnets in the circuits, but these latter would be unaffected by the alternate currents, which could, however, act on an electro-dynamometer used as a relay. Isham Baggs, in 1858, took out a patent for an arrangement for triple working. He used a magneto-electric current for deflecting a needle, a very powerful current which could have a chemical action on prepared paper, and very high tension currents which could perforate holes in paper strips. The patent of Hughes, taken out in 1858, is also for the combined use of battery currents and of induced currents. In 1871, Whitehouse proposed to make use of earth currents in conjunction with battery currents, each actuating its special instrument. As he puts it, the earth currents can be compared to the deep waves of the sea, slow and gradual in their motion, while the battery currents resemble ripples on the surface. Varley's patent, No. 1044, of 1870, is the forerunner of a great number of subsequent apparatus. He made use of rapidly undulating currents superposed on the ordinary currents, the former actuating special harmonic sounders. In 1876 Elisha Gray patented a combination of harmonic telegraphs with ordinary Morse instruments, which, in 1878, was modified by the introduction of telephones in the place of harmonic telegraphs. It is to the patent, No. 1477, of 1879, taken out by Messrs. Black and Rosebrugh, that we have to look for the first arrangement of two parallel telegraphic wires as a telephonic circuit. The telephones are interposed between the earth and a condenser, which stops the battery currents while it allows the passage of the undulatory telephone currents, and of alternate currents for ringing up. In this same year, 1879, we have Edison's American patent, No. 217,781, in which an arrangement is described capable of producing three variations of current. There is a key for reversing the current, a second for making variations in the strength of the current, and a vibrating reed for producing an undulatory current. Field's American patent, No. 242,411, of 1881, treats of a sextuple telegraph; two keys vary the intensity of the current, and a third produces harmonic vibrations; the receiving instruments are arranged to answer to each kind of current. Coming now to more modern systems, we have Van Rysselberghe's plan of combined telegraphy and telephony; similar plans by Maiche and Van der Weyde; a combination of the telegraph with the phonophore by Langdon Davies; and two duplex telegraphic systems, one by Edison and the other by Rosebrugh."

THE INFLUENCE OF MAGNETISM UPON CHEMICAL REACTIONS.—This is a subject of very considerable interest, and one in which, although very little work has yet been done, will probably well repay systematic investigation. The effects described below are not, we believe, absolutely new, although they are recorded by M. Colardeau in the last number of the *Journal de Physique*, and evidently under the impression that they are now given for the first time. But even if this be not the case the results will bear repetition. M. Colardeau takes a thin sheet of iron, underneath which the poles of a powerful magnet are placed. Copper is then deposited upon the iron from a solution of sulphate, when it is found that the deposit, instead of being of even depth over the surface, is cut up into numerous ridges. These ridges do not follow the magnetic lines of force, but are at all points orthogonal to those lines; they are, in fact, lines similar to those which the same investigator has found to be traced out by substances of low magnetic power when strewn in the form of powder over the magnetic field. (See *Electrician*, March 18th, p. 411). The hypothesis by which M. Colardeau at first attempted to

Digitized by Google

explain the effect was the following:—The deposit of copper from the solution of sulphate is in itself (in all probability) an electro-chemical phenomena, and may be considered to be due to a great number of extremely minute local couples, between which currents of electricity actually circulate. If this be the case, then these currents, under the influence of the magnet, will set up minute eddy currents in the liquid, which currents will be directed normally to the lines of force, and copper will be deposited chiefly along such streams. If, however, this explanation be correct, the plate of iron plays no necessary part in the reaction, or at least it might be replaced by a sheet of some other metal which is capable of reducing a copper salt. Acetate of copper and zinc should, for instance, give the same results; but, on making the experiment, a perfectly uniform deposit was obtained, and no trace was visible of the magnetic field. The first hypothesis must therefore be abandoned. The following considerations lead, however, to the establishment of a more consistent theory:—We know already (and a reason has been assigned in the note quoted above), that substances of low degrees of magnetic permeability tend to distribute themselves in the magnetic field in lines orthogonal to the lines of force. Now, during the chemical action, while copper is deposited, sulphate of iron is formed; but sulphate of iron is a substance of low magnetic permeability, hence it tends to form liquid filaments (if the term be permissible) which will lie along the direction already indicated. These filaments will exert a protecting influence upon the iron underneath, and will cause the copper to be deposited in ridges between them, and following, therefore, the same lines of direction. If this explanation be correct, the formation should be prevented by keeping the liquid in a state of agitation; and this is found to be the case. But M. Colardeau goes further than this, and renders the formation of the liquid filaments actually visible. In order to do so it is merely necessary to employ some salt of copper whose colour differs very distinctly from that of the corresponding iron salt. The best effect is produced by means of an alcoholic solution of bichloride of copper, which is green, while ferrous chloride is a deep yellow colour. The striæ formed by the iron salt are then clearly visible.

PROPOSED ABSOLUTE UNIT OF TIME BY ELECTRICAL MEASUREMENT.—The fact that our present system of measuring the flight of time, based, as it is, fundamentally upon purely astronomical observation, is not so rigorously exact as it was once supposed to be, is undeniable—and regrettable. Poisson was thought to have proved that a change in the length of the sidereal day amounting to one ten-millionth part in 2,500 years was incompatible with the occurrence of an ancient eclipse which the Chaldeans have recorded in their sculptures; and similar calculations were made by Laplace. But, alas! these great mathematicians were in error. It is not so. Slowly but surely the recurring tides are putting an effective drag upon the whirling earth, and it is calculated that already the day is longer from this cause than it was in the year 720 B.C. by as much as one part in 2,700,000. But this is not all; the velocity of the diurnal rotation of the earth is necessarily affected by anything which disturbs its moment of inertia about the axis of rotation, and this we know must be continuously diminishing—and, therefore, the velocity is being retarded—by reason of the secular cooling of the earth and its accompanying contraction in bulk. Only last week we read that a mountain peak in Arizona had been overthrown, and it is a mournful aggravation of the calamity to know that thereby the value of our present standard of time has been altered to an unknown and an unascertainable extent. The ceaseless fall of meteoric dust is a cause of still further discrepancy. Can nothing be done? How long shall science labour under the reproach that our fundamental unit of time is not constant even if ascertainable? The reproach cuts even more deeply when it is recognised that, for certain of the very same causes as we adduced above, the unit of mass labours under a similar charge of inconstancy, while, as for the unit of length, it has long relinquished even the pretence of having any foundation in Nature. It is true that many years ago Prof. Clerk-Maxwell expressed the opinion—an opinion in which we still venture with deference to concur—that the science of the future would base its fundamental units of length and time upon the exactly ascertained wave length and period of vibration of one selected light ray *in vacuo*. The conception is worthy of the genius of Maxwell, though even here we must perforce admit that a painful doubt creeps in. Who shall assure us that in the course of time the structure of the ether itself shall not undergo modification? At this point, as at so many others, the unwelcome conviction is forced upon us that it is the *relative* alone in which the human mind finds its appointed field of action—the absolute is synonymous with the unknowable. Failing, then, a loftier flight, does it not still remain a wise and legitimate quest to seek to attain as nearly as may be at least to constancy and accuracy in our standards? So, at least, thinks M. Lippmann, and far be it from us to dispute the proposition. M. Lippmann is also in all probability correct in tacitly assuming that the time has not yet arrived when Maxwell's suggestion can be adapted as a practicable scheme. He has therefore undertaken a new and thorough consideration of the subject—and this, it should be remembered to his credit, before the announcement of the fall of the Arizonian mountain peak—with the result that in a brilliant note recently presented to the French Academy he proposes a solution which is practically the following:—M. Lippmann, while retaining the element of time as one of our fundamental units, would make its value depend directly upon our knowledge of the unit of length. We have all been taught from our earliest (electrical) infancy that electrical resistance has the same dimensions as velocity. Sometimes, indeed, we say that resistance *is* a velocity, and then it is to be feared that we tend to get a little mixed. Now a velocity, it is needless to observe, *is* a length divided by a time; consequently, by a slight effort of the mathematical imagination it will become equally clear that the reciprocal of a velocity when divided by a length must be an expression signifying a time interval. We have also to observe with equal care that in the inscrutable wisdom of the physicists who have devoted their talents to the development of Fourier's "Theory of Dimensions," it has been decreed that resistance, while possessing always the same dimensions, should be expressed in *electrostatic* units, not directly as a velocity but as the inverse thereof. Once more, the *specific* resistance of any substance is a quantity which must necessarily vary directly with the unit of length. But it has been shown (axiomatically) that the reciprocal of a velocity divided by a length yields a definite period of time. Now, therefore, it is abundantly clear that making only the assumption that the specific resistance of a given substance, measured electrostatically, is an absolute and invariable quantity, then the electrostatic measurement of the specific resistance of any such substance yields AN ABSOLUTE MEASUREMENT OF TIME. Thus is our fundamental measurement of "the great independent variable," which Hobbes defined as "the phantasm of before and after," rescued from the accident of toppling crags or flowing tides, and securely based on the verification of the unit of length and the accurate determination of the electrostatic resistance of a cubic centimetre of mercury.

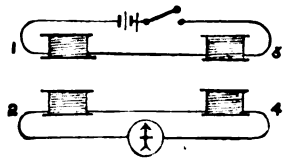
ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XXXIX.

BY OLIVER HEAVISIDE.

(Continued from page 459, Vol. XVIII.)

Felici's Balance Disturbed, and the Disturbance Equilibrated. Theory of the Balance of Thick Wires, both in the Christie and Felici Arrangements. Transformer with Conducting Core.

Referring to the last figure, in which imagine the galvanometer to be replaced by a telephone, and the key by an automatic intermitter, let us start with a perfect balance due to the M of one pair of coils being cancelled by the M of the other pair, and consider the nature of the effects produced by the presence of metal in or near either pair of coils.



First, let 3 and 4 be the coils of an inductometer, and 1, 2 other coils of any kind, separate from one another. The simplest action is that caused by non-conducting iron. It acts to increase or decrease the M of either or both pairs of coils according to its position with respect to them, and its effect can be perfectly balanced by a suitable increase or decrease of the M (mutual inductance) of the inductometer coils. Suppose, for example, the disturber is a non-conducting iron bullet, and is brought into the field of the coils 1, 2. If it be inserted in either coil, it increases their M. This is mainly because it increases the L of the coil in which it is inserted. If the two coils have their axes coincident, as in the figure, the bullet will cause their M to be increased by placing it anywhere on this axis, or near it. But if the bullet be brought between the coils laterally, so as to be, for instance, between the numerals 1 and 2 in the figure, the result is a decreased M. Here the L of each coil is little altered, and the decrease of M results from the lateral diversion of the magnetic induction by the bullet from its normal distribution. By pushing it in towards the axis a position of minimum M is reached, after which further approach to the axis causes M to increase, ending finally on the axis with being greater than the normal amount.

If the disturber be a non-conducting core (round cylinder), the greatest increase of M is, of course, when it is pushed through both coils, which are themselves brought as close together as possible, and when the core itself is several times as long as the depth of the coils. M is then multiplied about four times when the coils are about of the shape shown, with internal aperture about $\frac{1}{3}$ the diameter of the coils. If the coils be wound parallel on the same bobbin, the increase is much greater. If the whole space surrounding the coils be embedded in iron to a considerable distance, we shall approach the maximum M possible. The effective inductivity of the non-conducting iron is considerably less than that of solid iron, which counterbalances the freedom from F. currents.

Using solid iron, no silence is possible, owing to the F. currents, although there is a more or less distinctly marked minimum sound for a particular value of M. The substitution of a bundle of iron wires reduces this minimum sound, and when the wires are very fine, it is brought to comparative insignificance; but only by very fine division of iron are the F. currents rendered of insensible effect. It will be, of course, remembered that the range of the magnetic force variations must be moderate, so as to render the variations in the magnetic induction strictly proportional to them, otherwise no perfect balance is possible with non-conducting iron.

On the other hand, non-conducting (*i.e.*, very finely divided) brass (or presumably any other non-magnetic metal) does nothing. Diamagnetic effects are insensible. The above remarks apply, for the most part, equally well to the self-induction balance, except that iron always increases the L of a coil.

So far is very simple. It is the effect of the conductivity (in mass) of the disturbing matter that makes the interpretation of results troublesome. If the disturber be non-magnetic, we have a secondary current due to the action on the secondary circuit of the current induced in the disturber by the primary current; at least I suppose that this is the way it might be popularly explained. If the disturber be not too big, the M of the inductometer which gives the least sound (instead of silence) is sensibly the old value which gave silence before its introduction. If it be magnetic, there is also usually increased M. Changing the M of the inductometer to suit this, the minimum sound is still far louder than with an equally large non-magnetic disturbing mass (metallic) because the F. currents are so much stronger in iron. To this an exception is Prof. Bottomley's manganese steel of nearly unit inductivity, in which the F. currents should be, and no doubt are, far weaker than in copper, on account of the comparatively low conductivity. If this be not so, then it must be found out why not. Again, if the iron be independently magnetised so intensely as to reduce the effective inductivity sufficiently, then, as I pointed out in 1884, the F. currents should be made less than in copper.

To obtain an idea of the disturbance in the secondary circuit due to a conducting mass, let it be a simple linear circuit, and call it the tertiary. Let the suffixes $_1$ and $_2$ refer to the primary and secondary circuits, and $_3$ to the tertiary. Then the equations of E.M.F. are

$$\left.\begin{aligned} e &= Z_1C_1 + M_{13}pC_3, \\ 0 &= Z_2C_2 + M_{23}pC_3, \\ 0 &= M_{31}pC_1 + M_{32}pC_2 + Z_3C_3; \end{aligned}\right\} \quad . \quad . \quad . \quad (21c)$$

where $Z = R + Lp$, and e is the impressed force in the primary. Here M_{12} is missing, it being supposed to be properly adjusted to be zero. From these,

$$C_2 = \frac{M_{13}M_{23}p^2e}{Z_1(Z_2Z_3 - M_{23}^2p^2) - Z_2M_{13}^2p^2} \quad . \quad . \quad . \quad (22c)$$

is the secondary current's equation. The secondary current therefore varies as the product of the M of the tertiary and primary into the M of the tertiary and secondary. It is therefore made greatest by making coils 1 and 2 in the figure coincident (practically) by double-winding, and putting the disturber in their centre. In this case let R and L be the resistance and inductance of the primary and also of the secondary circuit, r and l those of the tertiary, and m the former M_{13} or M_{23}, now equal. Then (22c) becomes

$$C_2 = \frac{m^2p^2e}{zZ^2 - 2Zm^2p^2} \quad . \quad . \quad . \quad . \quad (23c)$$

But m is very small compared with L, so

$$C_2 = \frac{m^2p^2e}{zZ^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (24c)$$

Let the impressed force be sinusoidal; then $p^2 = -n^2$, making

$$C_2 = -\frac{m^2n^2e}{(r+lp)\{(R^2 - L^2n^2) + 2RLp\}}, \quad . \quad (25c)$$

Let $R = Ln$, which is a readily approximately reached condition. Then

$$C_2 = \frac{m^2}{2RL} \cdot \frac{ln^2 + rp}{r^2 + l^2n^2} \cdot e \quad . \quad . \quad . \quad . \quad (26c)$$

gives the secondary current in amplitude, $m^2n/2RL(r^2 + l^2n^2)^{\frac{1}{2}}$ per unit impressed force, and phase. If the tertiary could have no resistance, the secondary current would be of amplitude $m^2/2RL$ per unit impressed force, and in the same phase with it.

Now seek the conditions of balance by means of a fourth linear circuit placed between coils 3 and 4 in the figure, supposed to be identical with coils 1 and 2. Let the suffix $_4$ relate to this fourth circuit. Then (21c) become

$$\left.\begin{aligned} e &= Z_1C_1 + M_{13}pC_3 + M_{14}pC_4, \\ 0 &= Z_2C_2 + M_{23}pC_3 + M_{24}pC_4, \\ 0 &= M_{31}pC_1 + M_{32}pC_2 + Z_3C_3 + Z_4C_4, \\ 0 &= M_{41}pC_1 + M_{42}pC_2 + Z_4C_4, \end{aligned}\right\} \quad . \quad (27c)$$

Digitized by Google

Here, besides M_{12}, M_{34} is also missing, because of the distance between the two disturbers. From these,

$$\Delta C_2 = (M_{23}M_{31}Z_4 + M_{24}M_{41}Z_3)e \quad . \quad . \quad (28c)$$

is the equation of C_2, where Δ is the determinant of the coefficients in (27*c*). For a balance, the coefficient of e must vanish. This gives

$$\frac{r_3}{r_4} = \frac{L_3}{L_4} = -\frac{M_{31}M_{32}}{M_{41}M_{42}} \quad . \quad . \quad . \quad . \quad (29c)$$

If the coils of each "transformer" are coincident and equal, $M_{31} = M_{32}$, and $M_{41} = -M_{42}$; and, the M's being small, (28*c*) becomes

$$C_2 = \frac{M_{31}{}^2Z_4 - M_{41}{}^2Z_3}{Z^2Z_3Z_4}e, \quad . \quad . \quad . \quad (30c)$$

where Z is that of either the primary or secondary circuit.

We do not need to balance the disturber in one pair of coils by means of a precise copy of it in the other pair, similarly placed. It may be a reduced copy, according to (29*c*).

(To be continued.)

ELECTRICAL MEASURING INSTRUMENTS.*

BY SIR WILLIAM THOMSON, F.R.S.

(Continued from page 543, Vol. XVIII.)

The current-measuring instrument commonly called by the name of galvanometer, whether it be the sine galvanometer, the tangent galvanometer, or any of the different varieties of mirror galvanometers in use, is essentially magnetostatic. That is to say, it is an instrument in which a controlling magnet is used to balance the electro-magnetic force produced on a magnetised steel needle by a conductor or coil through which flows the current to be measured. In the sine galvanometer and tangent galvanometer, as originally used, and as still largely used for many important electrical measurements, the controlling magnet is the earth; but it is only in a locality far from dynamos and from wires carrying continuous† currents for electric lighting, that the terrestrial magnetic field suffices for a sine or a tangent galvanometer when any approach to accuracy is required; and thus in telegraph offices, workshops, and engine rooms it is generally desirable, if not absolutely necessary, to use a much stronger magnetic field than that of the earth for controlling the needle of a galvanometer; but whether the controlling magnet be the earth, or a steel magnet, its force is essentially inconstant, and therefore a magnetostatic galvanometer of any kind requires some means for determining from time to time the coefficient by which the absolute value of the current measured can be calculated from its indications, or a means of freshly adjusting the field to give any convenient absolute value to the readings on the scale of the instrument.

Sixteen or seventeen years ago I introduced a form of tangent galvanometer, which came to be called the "paddle-wheel galvanometer," from the appearance of the two coils being somewhat like the paddle-boxes of a paddle-steamer. In this instrument two coils adjustible to any desired equal distances on the two sides of the centre, act on a small needle, or group of small needles, hung by a single silk fibre, and carrying a pointer of about eight centimetres length, which shows deflections on a scale of unequal divisions proportional to the tangents of the deflections. Ordinarily the needle is acted upon by the terrestrial magnetic force alone; but sometimes in laboratory experiments a controlling magnet is placed either to augment or to diminish the controlling force on the needle. This instrument, though capable of considerable accuracy for absolute measurement in a locality free from local magnetic disturbance, was replaced by my graded galvanometers,‡ which have been found much more convenient for general purposes, and have been somewhat largely used since they were brought out five years ago. I have never, however, been satisfied with them, and I have been incessantly occupied in the attempt to produce an adjustible magnetostatic tangent galvanometer, which shall be both more convenient for ordinary use and more susceptible of high accuracy for scientific investigation than the graded galvanometers. I am not able this evening to show more than a half-finished attempt to realise this object, but I feel that I am now nearly touching it, and I hope at the commencement of next session to be able to place before you a working instrument of the magnetostatic class, which shall be thoroughly convenient for showing the number of lamps alight at any time in an ordinary dwelling house lighted by Edison-Swan lamps with direct current, and which shall also be available as a scientific measuring instrument to measure currents of from one to sixty amperes with a proportionate accuracy of one quarter per cent in the best part of its scale.

I have also made great efforts during the last six years to produce satisfactory constant standard instruments for measuring electric currents, and I have from time to time placed before you results in which the object was, to some degree, realised, but, as I have always told you, not satisfactorily. This time last year I placed before you and explained instruments depending on Faraday's discovery of the tendency of a globe, or cube, or short bar of soft iron, to move from places of weaker to places of stronger force in a magnetic field.* Two of those instruments which you saw, and which were then nearly completed, are again before you, and are now indicating the potential of the current by which we are lighted this evening. You see, when I increase the potential by reducing resistance, how the indicator shows—now an augmentation of 2½ per cent., which makes the lights considerably brighter—now again a diminution of one per cent.—and again the previous potential and the lights as they were. Since you first saw them these two instruments have been incessantly at work on the electric light wires in my house and laboratory, and have done good work all this time. I may say, in passing, they have allowed me to use much higher incandescence without risk to the lamps than would have been practicable without a trustworthy potential indicator, and personal, if not automatic, attention to regulate the potential according to its indications.

Though, however, they have so far been practically useful to myself, I am not satisfied with the instruments because they involve the use of soft iron, the retentiveness of which is always a serious trouble which I have only been able to keep within bounds, not completely to eliminate, by the use of the current reverser, which you see in connection with one of the instruments before you. I have, therefore, returned to the original discovery by Ampère of the mutual force between movable and fixed portions of an electric circuit, first utilised by Weber in his "Electro-dynamometer," to obtain a constant standard instrument for measuring electric currents without any of the trouble and residual inaccuracy entailed by the use of soft iron. After many trials I have succeeded in improving an electro dynamic balance, towards which I made a great many trials five years ago; and within the last three months I have succeeded in my laboratory in making accurate measurements of currents of from twenty milliamperes to 200 amperes by means of four instruments on the general plan of the rudimentary centi-ampere balance before you, in which a single movable coil is repelled and attracted upwards by two fixed coils, one below it and the other above it, and the total of the electro-magnetic force is balanced by a weight hung on a knife edge attached to the balance.† At the commencement of next session I hope to show you some of these instruments in a state fit for practical work. In the meantime I can only thank you for the patience with which you have listened to me this evening, and for the kindness with which now, as on previous occasions, you have allowed me to bring half-done work before you, and to tell you of what I hoped to do, but had not yet done, in the way of producing practically useful instruments.

* "On a Double Chain of Electrical Measuring Instruments to Measure Currents from the Millionth of a Milliampere to a Thousand Amperes, and to Measure Potentials up to Forty Thousand Volts." Paper read before the Philosophical Society of Glasgow, April 20th, 1887.

† The neighbourhood of a conductor carrying an alternate current for electric lighting, however strong, would not disturb the terrestrial magnetic field for a sine galvanometer or tangent galvanometer in its neighbourhood.

‡ Patent No. 5,668, of 1881 (26th December).

* Patent No. 11,106, 9th August, 1884.

† Patent No 2,028, 21st April, 1883.

CORRESPONDENCE.

THEORY OF SECONDARY CELLS—ELECTRIC EQUIVALENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: No doubt my friend D. G. FitzGerald is fully able to defend his own position. I feel impelled, however, to make some remarks upon Mr. Swinburne's letter, page 562, because the subject is one which was familiar to me at a time, years ago, when it was outside ordinary electric knowledge, and, in fact, almost unknown to electricians generally. Mr. Swinburne accuses Mr. FitzGerald of mixing up the new chemical notation and the old calorific values of chemical affinity. He sets his own position down thus: "In old days, when water was H O, it was correct to say Andrews's value for Zn O is 42,408; but now that water is H_2 O, Andrews's value is 84,816." I submit that in this statement it is Mr. Swinburne who mixes things up. What we have to consider, is not the molecular constitution of each individual substance, and the calorific value of such molecules, involving a constantly-varying datum value, the whole question is the equivalence of chemical affinities and E.M.F.—the relation, that is, of calories and volts.

Mr. Swinburne does not attach importance to this, because, as he says, he holds "that the E M.F. of a cell cannot be measured by the heats of combination, and that the heats of combination are not measures of chemical affinity." Mr. Swinburne should not be blamed for refusing to adopt the nearly universal opinion of scientific electricians and chemists; but, unfortunately, he sets himself against the facts, and that is always an unfortunate and difficult position to hold.

I may here say that it may be difficult always to trace exactly the relation and make the figures balance; but this is because the values themselves are as yet only approximately known, being difficult to measure exactly; and that an important element of calculation is generally omitted, *i.e.*, the heat of solution + or − of the various substances, in the quantity of water, &c., present in each case. But how is it possible to get an exact datum? The value depends upon the relative values of the volt, ohm, and ampere. Will any electrician be good enough to tell us what those units mean? What is their value, and what is the true mechanical equivalent of a "volt-ampere-ohm-second?" Until we get rid of the absurdity of the "legal" ohm, &c., related to no actual thing or system, but only to the erroneously fixed length of a column of mercury, which no one ever made or ever will make, and come back to the true units, the decimal multiples of the absolute units, there will be nothing but confusion possible.

However, we have to value the relation of chemical affinity, *i.e.*, *calories*, to this undetermined and unstable balanced electric unit. To speak of expressing volts in calories is absurd. The one is mere pressure, the other is kinetic energy. The "volt-ampere-ohm-second" is energy, and can be expressed in calories, foot-pounds, or any other unit of work, and the relation of E.M.F. to calories depends upon the number of these volt-ampere-ohm-seconds expended in doing an equivalent of chemical work.

Now the new notation of chemistry, while it has greatly set aside the idea of equivalents in our calculations, is none the less based upon that idea. *Its basis is one atom of hydrogen*, and its molecules become bivalent, tri, hex, &c., just as they are in their constituent ions equivalent to 2, 3, 6 univalent or hydrogen atoms. This is so in chemistry, though often ignored; but we cannot ignore it in the electric relations which include only molecules capable of division into two ions. Therefore, Mr. FitzGerald is entirely right in using a fixed unitary value,

$$\frac{\text{Atomic weight}}{\text{Valency}} = \text{Electric equivalent},$$

which means basing the calorific values on the relation of one atom of hydrogen, not upon two because we write water as H_2 O.

In the present uncertainty of what the various electrical units mean, I have reckoned that under unit conditions one ampere current takes 97,808·5 seconds to effect one gramme equivalent of electrolysis, and that the energy corresponding to this effected by one volt and in one ohm is 23,287·7 calories. This of course represents the 23,000 calories of Prof. S. Thompson, and no doubt we shall know some day what the exact value is. At present I am only concerned to maintain that this value is the proper one to use always, and that we should reduce all molecular calorific values to the terms of the equivalent in grammes of each substance; that, therefore, it is confusing and erroneous to call the volt equivalent (what I first called the "equi-volt") sometimes 23,000, sometimes 46,000, or generally $23{,}000 \times n$, merely because the molecules may have valencies of $1 \times n$.—Yours, &c.,

JOHN T. SPRAGUE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I imagine Mr. Swinburne would agree that heat of combination is principally *chemical* energy transformed, and that it is accordingly a true measure of chemical affinity if corrected for accessory causes, increasing or diminishing the heat due to that source. For instance, heat resulting from a liquid constituent combining as a solid, or *vice versâ*, will obviously have no counterpart either in chemical affinity or in volts, and must be discounted in the estimation. But I am unwilling to regard his bookkeeping as a calculation that errs in its principle and purpose. However, while Mr. Swinburne so particularly refrains from asserting that the E.M.F. is the measure of the chemical affinities, I unhesitatingly commit myself to this opinion, and would like to say that the E.M.F. *is* the chemical affinities, or the resultant of them.

I am surprised that the expression "electrolytic thread" did not find in Mr. Swinburne's mind an answering idea; and yet he asks me what I mean. If in accusing me of "hypotheses" he means mental conceptions of what takes place in nature, it is no crime to own them, while it is a serious defect to be without them. I know that I feel angry when I hear of "contact potential differences," and that I am only half appeased when the expression is explained to mean *don't-know-why* potential differences; but all this is quite consistent in me. I commend people who foster good mental conceptions, and the only case in which I object to hypotheses is when people set aside the explanation which Nature herself suggests, and invent an agency of their own which they impute to Nature, and so fill up the gap of mystery. However, as to the electrolytic threads or chains, Mr. Swinburne will find pictures of them in Sprague's "Electricity," second edition, p. 118, art. 150, and p. 359, art. 585; also in Dr. Ferguson's "Electricity" (edition 1886), on p. 113, and doubtless in many other books.

As regards the disputed question of crediting the sulphate of lead at the peroxide plate, the point rather is whether this action is really a part of the process of discharge and not a local and extraneous action merely accompanying it, like the formation of sulphate of zinc on the brass plate in the case suggested by Mr. FitzGerald. I feel assured, for reasons previously mentioned, that it does not belong *directly* to the process of discharge, though at the same time I dare not say that it is entirely independent and unconnected with it. In my first letter I contemplated the possibility of this action modifying the E.M.F. of the lead cell, and I will now show in what manner this may occur. It is not unlikely that the *actual* bond of affinity with O in Pb O, O is weaker in presence of the rival acid radicle of an $H_2 S O_4$, not itself forming part of any polarised chain from plate to plate, but exercising a side influence, and tending to reconstitute itself by supplying $S O_3$ to Pb O, with the result of $Pb S O_4 + H_2 O$. Accordingly, a lesser amount than otherwise would have to be debited for Pb O, O decomposed.

I am quite aware that I am here answerable for another of my "hypotheses," but it is one that I can justify by illustration. Gold forms no chloride in plain H, Cl, because the bond H, Cl is sufficiently stable not to be ruptured by affinity between the gold and the chlorine. But H Cl mixed as *aqua regia* does attack gold, because the oxidant nitric acid seduces the H, and the partnership H Cl is therefore more easily dissolved. Again, how is it that sodium sulphate can be electrolysed by

Digitized by Google

an E.M.F. quite unequal to the force of combination Na_2, SO_4? How is the alliance $Na_2 SO_4$ sundered? The secondary action, which forms caustic soda so far as it is a *subsequent* process affords no explanation; I could not lift 4 cwt. from the ground because I had means to support it *afterwards*. The explanation is, I believe, that secondary action exists *as an effort* simultaneously with the primary or true electrolytic action, and the $\overline{OH}$ of the water of solution acts seductively, so as to diminish the force of the bond Na_2, SO_4, making the real amount to be debited in decomposing Na_2, SO_4

$$Na_2, SO_4 \text{ less } [2\,Na, OH \text{ less } 2\,H, OH]$$

or the sum of $Na_2, SO_4 + 2\,H, OH$, less $2\,Na, OH$.

On the whole, in reckoning the chemical affinities in the lead cell my feeling is that the amount which should be debited for PbO, O decomposed is something very small, while the assets have the benefit of the O combining with hydrogen in addition to Pb, SO_4. The looseness of the combination PbO, O in presence of acid, and the semi-detached condition of the second O, may be gauged by the property which lead peroxide possesses of decomposing HCl. Nature here shows us that the *unsatisfied* affinity of O in PbO_2 is stronger than that of the Cl, which it deprives of the hydrogen.—Yours, &c.

37, Burlington-road, W. E. ALDRED WILLIAMS.

LONG DISTANCE TELEPHONY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your article on telephonic enterprise in this country, especially in London, you mention that the United Telephone Company are going to bestir themselves, and intend getting some one from America to re-organise the system here. In my opinion—but of course I may be wrong—the Americans will do the company no good. It is they who inaugurated the system here, and we have to a great extent worked on the American system ever since, especially in our construction, and it is in that where we have failed. I wish to point out that the electrician who has gained his experience in America is totally unfitted to carry out work in England. He has been trained in a climate which is exceptionally dry; he naturally ignores the necessity for insulation here, because in America Nature has made it an item of little consideration.

Our climate during the greater part of the year is exceptionally a damp one, and more than this, our atmosphere, especially in our large cities and manufacturing districts, is charged with carbon dust. It is this dirt on the surface of our insulators, made more or less conducting by the moisture of the atmosphere, which causes all our difficulties.

A film of wet carbon particles on the surface of the insulators causes low and intermittent insulation and consequent disturbances, which are in many cases falsely ascribed to induction.

Prof. Thompson some time ago said he thought that a good deal that was put down to induction was due to leakage. I have not heard him say much on the subject since; perhaps his investigations in telephonic instruments have drawn his attention from the importance of construction.

In our dirtiest districts every insulator is theoretically a minute microphone, and if it is, each insulator is a source of disturbance, more or less, in accordance with the amount of moisture in the atmosphere.

Why I think that every insulator that is covered with carbon is a minute microphone is from the fact that the surface of the insulators is coated with a film of wet carbon, and it is the wet carbon filament interposing by means of surface leakage between line and earth that is the source of trouble. In our climate the quality of the insulators has little or nothing to do with the actual dielectric resistance of the line, it is entirely a question of surface leakage.

To give you an instance of the state of the atmosphere affecting insulation, the late Messrs. Laws and Hockin, when in Sydney, New South Wales, tested a land-line the dielectric resistance of which was 1,500 megohms per mile; this high insulation was in no way due to superior construction, but simply to the dry, clean state of the atmosphere, and no surface leakage.

Here, in England, the Government engineers would be contented with 1·5 megohm per mile right through the year. We shall never make advances in long-distance telephony until we get proper insulation; and those who have worked in dry climates are apt to ignore this important necessity; they are accustomed not to think about it.

Mr. W. H. Preece has made some successful experiments on long-distance telephony; but when he experiments he is careful enough to go some distance from London, and to avoid the region of dirty insulators, consequently his experiments are more theoretical than practical. I should like him to carry out some experiments from the centre of London to the centre of Liverpool or Manchester, especially on a line that has been erected for some years.

There are some other experiments that might well be made. I have said that our climate is an exceptionally damp one for the greater part of the year; but between the months of February and May we generally have east winds; it is then that our climate is dry.

Has Mr. Preece, or any of the engineers interested in long-distance telephony, noticed if there is less disturbance or that better results are obtained when an east wind or a north-east wind is blowing than when a south-west wind is blowing?

It is possible to construct a land-line in England, notwithstanding our damp and dirty atmosphere, which could give a constant dielectric resistance of, say, 1,000 meghoms per mile, and if the United Telephone Company is going to undertake long-distance lines I would strongly advise it to pay some attention to the all-important question of insulation, otherwise its money will be spent in vain.—Yours, &c.,

H. C. DONOVAN.

Morden Wharf, East Greenwich, May 9th.

CARDEW'S VOLTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Those of your readers who are users of the above instrument may be interested to hear that the very annoying oscillation of the index, due to air currents in the tube, may be entirely stopped by using the voltmeter in a horizontal position. As the weight of the working wire causes the deflections to be somewhat reduced, decalibration is necessary before using a voltmeter in the new position.

This simple remedy for a grave defect is due to Mr. G. S. Ram.—Yours, &c., SYDNEY EVERSHED.

P.S. Since writing the above I learn that Prof. Ayrton discovered the same remedy some twelve months since. I think that many others will join me in regretting that this useful knowledge has been so long buried in the professional bosom.

Westminster, 11th May, 1887.

VARNISHING INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am pleased to see by Mr. Shippey's letter in your issue of to-day that my note on varnishing incandescent lamps has excited so much interest as to have been "recopied into many scientific journals." This is an honour I did not expect.

With regard to Mr. Shippey's advocacy of coloured glass in preference to varnishing, allow me to make one or two remarks. In the first place, I did not advise the use of either one process or the other. There was a paragraph in *The Electrician* stating that Messrs. Siemens and Halske had adopted a system of varnishing, and having had some experience in the matter, I sent you some practical details as to the best mode of doing this.

If the question were asked, What is the *best* mode of obtaining the effect of a coloured lamp in incandescent work? I

Digitized by Google

should say without hesitation that it is neither the one I described nor the one Mr. Shippey advocates; but I should say the *best* way to arrive at the required result would be to put the plain lamp into a coloured globe. The use of coloured glass in the original manufacture of the lamp, which Mr. Shippey so strongly advises, is open to the fatal objection that a lamp made with a coloured glass globe cannot be *tested photometrically*, and there are therefore no means of knowing whether it is running at the desired temperature.—Yours, &c.,

NELSON H. CHERRILL.

London, May 6, 1887.

ELECTRICAL PHENOMENA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me a short space in your paper to ask if any of your readers have observed the following phenomenon?

I have noticed a brush of light playing at irregular intervals between the strap and the extreme edge of the disc or fly-wheel of a dynamo.

Is this due to leakage; and, if so, why does it take place at this point and not where the strap is in contact with the pulley? The pulley and disc are in one piece, and there is no resin on the strap.

Or is it due to an E.M.F. generated in the disc as it revolves in the field of the magnets similar to a Barlow wheel?—Yours, &c.,

LEAKAGE.

A NEW METHOD OF REGULATION IN THREE-WIRE DISTRIBUTION.

In the usual method of distribution on the three-wire system the current furnished by the dynamo passes to the main and then through a group of lamps to a connecting wire, from which it passes through another group of lamps to the other or return main, and thence to the dynamo. Such a system ordinarily requires that the energy of current or number of lamps be equal for each multiple arc group—that is, that the groups be "balanced;" but where this is not the case, a compensation may be secured by the employment of resistances placed in branch circuit around the group containing the fewest lamps, or in which the smallest current is needed.

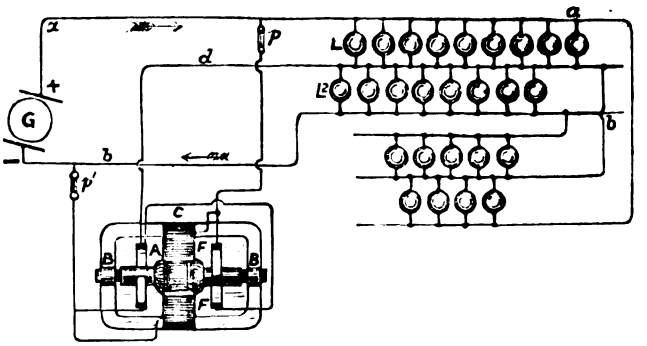
In a new arrangement designed by Prof. Elihu Thomson, to effect proper regulation of the current in each group of lamps, the compensation is rendered automatic, and at the same time a transfer of energy is made from the parts of the circuit where it would otherwise be in excess to those parts which require more. Prof. Thomson accomplishes this by combining with the mains of a multiple-arc series, or three-wire system, a converter which permits of the extinguishing of lamps in any multiple-arc group at will, relying upon the compensating apparatus to effect a proper balance.

The manner in which this is accomplished is illustrated in the accompanying diagram. In this G represents the generating dynamo, which maintains a fairly constant difference of potential between the mains *a* and *b*. The potential is sufficient to work two multiple-arc sets of lamps in series, as indicated at L L^2. The intermediate wire *d* unites the two sets.

Now, in operating such a system, so long as the number of lamps in L and L^2 be equal, or the current in both is alike, no difficulty will be experienced; but should a change take place, as by the extinction of a part of the lamps in the set L^2, an excess of current will traverse the remaining lamps of the set, increasing their brilliancy, and tending also to decrease the brilliancy of the lamps in group or set L.

Any attempt to adjust matters by changing the potential at the generator G is without avail. To overcome the difficulty Prof. Thomson attaches to the mains *a b d* what he terms a "compensator" or "converter," for current energy. One of his best arrangements is illustrated at C in the engraving. It consists of a sort of dynamo-generator or motor, or rather a combination of the two. The field-magnets F F are connected, one terminal to *a* and the other to *b*, as a shunt to the circuit or branch from *a* to *b* of rather high resistance, so as to demand but a very small fraction of the current.

The armature A is wound with a double winding or two separate and insulated sets of coils, which are, however, the counterparts of each other in electromotive energy. The armature-windings or sets of coils are each provided with a separate commutator and brushes, shown to the right and left of the armature A. The armature windings are made of quite low resistance, and of such length of wire that they will give, respectively, when revolving in the field F F at a high-speed, an electromotive force equal to that which normally exists between *a* and *d* and between *d* and *b*—*i.e.*, the voltage of the lamps used in L and L^2.



The connections are made as shown. If *a* be the positive wire of G, then *b* will be negative, and *d* nearly neutral, when the lamps in L and L^2 are equal in number. A wire is carried from *a*, through a fusible plug, *p*, to one of the brushes of the compensator C, which brush, when the armature A is revolved, will receive a counter electromotive force from the commutator segments, tending to oppose the potential of *a*. The opposite brush is connected to *d*. On the other side, as shown, and at the other commutator a brush is connected to *b* in like manner, so that when revolved the armature A will give a counter force to oppose the potential of *b*. The opposite (upper) brush is connected to *d*. The apparatus and circuits thus arranged will give the following results:—

Assuming the demand for current in L and L^2 the same, the potential between *a* and *d* will be equal to that existing between *d* and *b*. The armature A will receive current at both commutators, tending to short-circuit from *a* to *d* and from *d* to *b* through each set of coils on it. The result of current passing in A, if the brushes on the commutator be set on the neutral line, will be to drive A as a motor without load, and its speed of rotation will continually increase until the counter potentials developed in its coils almost neutralise the potentials between *a* and *d* and *d* and *b*, so that little current flows in A, and only enough to keep up the speed of A.

Now let some of the lamps L be cut off. The potential between *a* and *d* will at once rise, and that between *d* and *b* will fall, because the resistances are now no longer evenly distributed from *a* to *b*. As the resistances of the windings on A are quite low, more current will now pass from *a* to *d* through one winding of the compensator-armature A, and it will run faster than before. The device will now act as a generator to give current back to the circuit between *d* and *b* by the other winding, or, in other words, it becomes a motor-generator running by the higher potential to feed the main having the lower, and the action will occur with either winding on A, according as the higher potential exists between *a* and *d* or between *d* and *b*, the higher potential sending current through the motor-generator C and inducing current in the other armature-winding, which is fed out to raise the lower potential. It is essential that the resistances of the windings on A be so low as to be negligible.

As will be seen, under the conditions outlined above, the apparatus acts as a converter for turning or converting the electric energy or potential existing between one pair of mains into electric energy or potential between another pair, so as to effect an equalisation. As it is usually only necessary to provide for a partial extinction of lamps in either group, the compensator C is small compared to the generator G, and, furthermore, its effectiveness can be enhanced by constructing it to run at very high speeds, as it requires no belts, and there is no strain on its bearings.—*Electrical World.*

WESTERN AUSTRALIA.—Mr. William Helmich, the Postmaster-General and General Superintendent of Telegraphs in Western Australia, will retire on a pension at the end of June, after a long service of 40 years. The Secretary of State for the Colonies has conferred the appointment upon Mr. Charles F. Gahan, of the Colonial Civil Service, who will leave for King George's Sound by the "Chimborazo" on Saturday.

TENDERS FOR ELECTRIC LIGHTING.

Often as we have had bitterly to complain of hindrances thrown in the way of Electric Lighting by external hands, our complaints against the obstacles created from within have been hardly less frequent or less severe. It is bad enough to have to contend against powerful vested interests, against unscrupulous speculation, and against deep rooted prejudices; but these may be overcome by patience and time. What is even more vexatious and more difficult of correction is the short-sighted selfishness of electrical engineers themselves. We have on several occasions within the past two or three years pointed out the unwisdom of their opposing each other with a competitive zeal which would be appropriate only to an understocked market and a brisk demand. Further, we have urged upon them the urgent necessity for coming to a friendly understanding, and for combining with a view not merely of promoting legitimate business, but of preventing all attempts at business of the opposite description. To a certain extent our advice has been followed; but there is still room for a wider, closer, and more influential association than any that at present exists among electric lighting engineers, as is evident from such paragraphs as the one relating to the Southport tenders printed in our last week's issue—paragraphs, we are sorry to say, that are not of very rare occurrence.

We inserted the case above referred to as descriptive of "The Way Electric Light Business is Lost," and a reperusal of the facts will, we think, fully bear out our description. It seems that, for some reason which we do not pretend to understand, the manager of the Southport Gasworks recently invited and obtained tenders for lighting by electricity one of the streets of that town. Here was a case for extreme caution. We shall not be suspected of advising collusive tendering; but if ever there was an occasion for preliminary understanding among the intending applicants this was one. There should, for example, have been no conflict as to the amount of illumination required for the specified area; any serious divergence among them on this point would at once betray ignorance of their own profession, or a presumption of ignorance on the part of the person tendering—either of which might be fatal to the reputation of all the tenderers alike. Neither should there have been any great disparity in respect to the cost of an installation which appears to have presented no peculiar difficulties or problems outside the ordinary experience of everyday work. Still less should we expect to see any striking difference in the estimates for the annual maintenance of such a simple installation as this.

On none of these points, however, was there any sort of agreement among the fifteen firms who tendered for the job; on the contrary, their divergences were so great that it is evident that either they do not know their own business or that they suppose nobody else does. The space to be lighted, 14,000 yards in length and 30 broad, was specified, as was also the power (2,000 candles) of the lamps to be employed. In all else the tenderers were free—a good deal too free, apparently, for in every detail they differed so widely that it is impossible to avoid the conclusion that some at least of the offers were made not for business but for advertisement. We have not the whole particulars before us; but, broadly, the number of lamps estimated in the lowest tender was six, whilst in the highest it was fifty, the other estimates ranging indiscriminately between these two extremes. As regards the cost of the installation, the estimates varied from £695 to £3,625—a difference great enough in all conscience for so small an undertaking, but not nearly so great as it ought to be considering the diversity of estimate in regard to the number of lamps. In respect to annual maintenance the proportion is more consistent, being £72 on the one hand and £663 on the other; but on that very account the whole calculation is rendered transparently untrustworthy.

It is easy to be seen that the lower estimates have been accidentally or intentionally miscalculated, and that the work could in no circumstances be done for the money. But this is not a view of the case we can expect outsiders to take of such incidents, certainly not the managers of gasworks. Of course the scheme was abandoned altogether, and the fifteen tenderers have only succeeded in bringing ridicule on their profession, and doing serious injury to electric lighting business generally. The Southport Gasworks manager probably drew the natural inference that either the lowest was a bogus tender or that the highest was a fraud; and that most of the remaining thirteen tenders were more or less of the same character. Probably, also, he came to the conclusion that a profession which varied so greatly in its estimate of things was not quite to be trusted yet awhile. No one can be surprised if the people of Southport do not renew their overtures to the electric light for some years to come. These incidents are the more deplorable, because they often provide the local authorities with precisely the excuse they desire for declining to accede to the wishes of the inhabitants in respect to electric lighting. If this kind of indiscriminate

Digitized by Google

and reckless tendering goes on much longer, all that any section of a local board opposed to the electric light need do to insure its rejection will be to agree to submitting an installation to public competition. The tenders will duly arrive, and if they resemble in any way those upon which we have been commenting, the result is certain. Electrical engineers have the remedy in their own hands, and we invite them to lose no time in taking the matter seriously into their consideration.

AUSTRALASIAN TELEGRAPHY.

We give below the final proposals made by the Eastern Extension Telegraph Company, submitted by Mr. J. Pender, the chairman of the company, to the recent Colonial Conference. It will be seen that the concessions offered by the company are of a very substantial nature; the existing tariff would be reduced to less than one-half. We have again and again pointed out that the telegraph companies could not possibly undertake even the temporary loss of income due to so great a lowering of the tariff, and naturally they ask that the risk should be minimised by a guarantee from the colonies interested to the extent of three-fourths of the existing revenue, the companies themselves participating in the risk, and therefore in the guarantee, to the extent of one-fourth of the existing revenue. This proposal shows that the companies are desirous of meeting the demands made upon them for a cheaper tariff, and the management goes as far as, even if not a little farther than, is consistent with its duties to the shareholders. It must be recognised that there is not, never has been, nor ever will be, a time when the claims of the shareholders in a private company can be ignored, and in considering a question of this magnitude that question must never be forgotten. The directors of the companies working the cable system to our eastern colonies have always been conspicuous for their efforts to make the system as perfect as possible, and little inconvenience has ever arisen from interruption of traffic. Their offer is now before the public, who will, we venture to predict, agree with us in regarding it as a businesslike and liberal concession.

Proposition of the Eastern Extension Company to the Australasian Colonies, subject to the Approval of all the Interested Administrations.

That they should guarantee to the companies carrying Australasian telegrams, viz.:—The Eastern, Indo-European, and Eastern Extension Companies, their annual revenue based on the average of the three years ended 1886, for 13 years, the unexpired term of the duplicate Cable Subsidy, and make the through tariff 4s. per word. At the end of the term the question would have to be reconsidered with a view to a fresh arrangement.

Average annual traffic receipts of the three companies from Australasian telegrams, exclusive of existing subsidies, viz.:—

Eastern	£52,300	
Indo-European	7,700	
Eastern Extension	125,000	
	£185,000	
Estimated revenue at a 4s. tariff between Europe and Adelaide, based on present traffic, and assuming that South Australia accept a transit rate of 5d. per word:—*(See table below)*	80,000	
		£105,000
The companies will take the whole risk of any falling off of traffic receipts below £80,000, and also accept one-fourth of the guarantee risk, viz.:—	26,250	
Leaving as the *maximum liability* of the colonies if no increase of traffic takes place	78,750	
		£105,000

If the traffic receipts increased by:—

25 per cent. the colonies would have to make up	£63,750
50 ,, ,, ,, ,, ,,	48,750
75 ,, ,, ,, ,, ,,	33,750
100 ,, ,, ,, ,, ,,	18,750

distributed as follows:—

GUARANTEE.

Colony.	Population based on 1885 Statistics.†	Amount to be made up, exclusive of Subsidies, if Traffic increased by 25%.	50%.	75%.	100%.
Victoria	991,869	£19,029	£14,552	£10,074	£5,597
New South Wales.	957,914	13,379	14,055	9,730	5,406
South Australia..	313,423	6,012	4,597	3,183	1,768
Western Australia	35,186	676	517	358	199
New Zealand	575,226	11,035	8,439	5,842	3,246
Queensland	315,489	6,050	4,626	3,203	1,779
Tasmania	133,791	2,569	1,964	1,760	755
Total	3,322,898	£63,750	£48,750	£33,750	£18,750

†These are the most recent statistics in the company's possession, but the latest ascertained populations would, of course, form the basis of the calculations.

If the subsidies were pooled and distributed over all the colonies according to population, result would be as follows:—

SUBSIDIES.

Colony.	Existing contributions in respect of Duplicate Cable on 1881 census.	Contributions in respect of New Zealand and Tasmanian Cables.	Contributions if subsidies spread over all colonies on basis of population, '85.
Victoria	£14,479	—	£13,164
New South Wales..	12,617	2,500	12,714
South Australia	4,805	—	4,159
Western Australia.	499	—	467
New Zealand	—	5,000	7,634
Queensland	—	—	4,185
Tasmania	—	4,200	1,777
	£32,400	£11,700	£44,100

The following table shows the contribution of each colony if subsidies and guarantee combined and distributed over all colonies, according to population on basis of 1885 statistics:—

SUBSIDIES AND GUARANTEE COMBINED.

	25%	50%	75%	100%
Victoria	£32,193	£27,716	£23,239	£18,760
New South Wales	31,093	26,769	22,444	18,121
South Australia	10,170	8,756	7,341	5,926
Western Australia	1,143	984	825	666
New Zealand	18,669	16,072	13,476	10,879
Queensland	10,235	8,811	7,388	5,965
Tasmania	4,347	3,742	3,137	2,533
	£107,850	£92,850	£77.850	£62,850

PRESENT TRAFFIC SHOWING PROPORTIONS AT 4s. TARIFF.

Class of Traffic.	Number of words.	Companies' proportion of 4s. Tariff.	Outpayments.	Total Tariff.
		s. d.	s. d.	s. d.
Ordinary	489,000	2 5½	1 6½	4 0
Government	41,000	2 5	1 6½	3 11½
Press	70,000	1 11	0 9	2 8
Local (including India)	54,000	3 0	1 0	4 0
Total	654,000			

The above proposition is based upon a continuous service and freedom from competition. In the event of the communication being totally interrupted, the guarantee to continue for a period of one month.

Since the Australian cables were duplicated in 1880 the service with Australia has been interrupted for only 26 days, or on an average of less than four days annually.

AN EIGHT-LIGHT DYNAMO.

BY GEO. M. HOPKINS.

Unfortunately for the tyro in electrical matters, no rule or set of rules exists in the literature of dynamo-electric machinery which would enable him, with entire confidence of success, to plan a new form of dynamo, or even to attempt to construct any one of the well known forms. The available information generally fails in some minor details, thus, in some degree, obscuring the whole subject, and awakening doubts as to the best course to pursue. One might follow such information as closely as possible, and proceed so far as to make an operative machine, and yet it might happen that no current could be evoked from it, simply for the want of specific knowledge as to how to secure the first increment of magnetism necessary for starting the inductive process. * * *

It is not the purpose of the present paper to treat on dynamos in general, but to give, as fully as possible, specific information as to the construction of a small dynamo-electric machine capable of supplying a current for eight 16 candle-power incandescent 50-volt

Digitized by Google

lamps, or a larger number of smaller incandescent lamps of suitable resistance, or an arc lamp of ordinary power. The armature speed is 2,200 revolutions per minute, and the machine running normally requires one horse-power to drive it. The machine weighs 130lb, and occupies a floor space of 8in. by 18in. The dimensions of the machine are tabulated below :—

Height of field-magnet	13	inches.
Length of field-magnet waist	6⅞	,,
Width of field-magnet waist	5⅜	,,
Thickness of field-magnet waist	1⅝	,,
Depth of polar extremities from waist to base	4½	,,
Width of polar extremities	6¾	,,
Thickness of polar extremities	3	,,
Diameter of bore of polar extremities	3⅝	,,
Thickness of yoke	1⅞	,,
Diameter of bolts passing through the yoke	⅝	,,
Length of armature shaft	18	,,
Diameter of armature shaft	⅝	,,
Diameter of armature shaft bearings	¾	,,
Length of parallel faces of armature	6¾	,,
Diameter of iron rings of armature core, outside	3	,,
Diameter of rings of armature core, inside	1⅞	,,
Thickness of rings	1/32	,,
Number of iron rings on armature core	39	
Diameter of wooden armature core	1⅞	,,
Length of wooden armature	6⅝	,,
Length of armature core	6⅝	,,
Number of divisions of the armature core	24	
Number of divisions of the commutator cylinder	24	
Length of commutator cylinder	2	,,
Width of brushes	⅛	,,
Size of wire on armature, No. 20 Am. W. G.	0·027	in diam.
Length (approximate) of wire in each armature coil*	25	feet.
Number of convolutions in each layer	8	
Number of convolutions in each coil	16	
Number of layers in each coil	2	
Number of coils in each space of the armature	2	
External diameter of armature	3⅜	inches.
Weight of wire on armature	2¼	pounds.
Diameter of pulley on armature shaft	3½	inches.
Width of pulley on armature shaft	2½	,,
Width of driving belt	2	,,
Size of wire on field-magnet, No. 18 Am. W. G.	0·033	in diam.
Number of parallel wires on each leg of field-magnet	4	
Number of layers of wire on each leg of field-magnet	8	
Number of layers for each wire	2	
Weight of wire on field-magnet	17	pounds.

The field-magnet is made of two like parts of soft, grey cast iron, joined at the centre of the yoke, and bound together by two bolts, as shown in Fig 1. The adjoining surfaces of the yoke are accu-

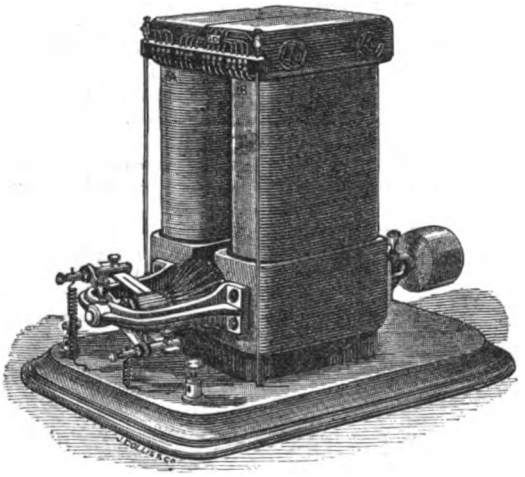

Fig. 1.—Eight-light Dynamo.

rately faced, so that when clamped together the connected halves of the magnet will be practically the same as if made integrally.

The bore of the polar extremities of the magnet is 3⅝in. in diameter, and the sides of the magnet around the bore are faced in the lathe to form a true support for the bronze yokes supporting the ends of the armature shaft. These yokes are bored to receive the armature shaft, and faced in the lathe upon the surfaces abutting against the sides of the magnet. The yokes are secured in their places on the magnet with their centres coincident with the axis of the bore of the magnet.

The armature shaft is fitted so as to revolve freely on its bearings, and there is a clearance between the periphery of the armature and the magnet of about ⅛in. Upon the portion of the armature shaft lying between the poles of the field-magnet is placed the cylinder, of seasoned hard wood of the size above given. Upon this wooden cylinder are placed the thirty-nine iron rings or washers, with intervening paper rings of the same size and about 1/32in. thick. The iron rings are drilled at diametrically opposite points to receive the brass rods by which the entire series is held together. The arrangement of the parts of the core of the armature is shown in Fig. 2, in which some of the iron rings have been separated, to more clearly illustrate the construction.

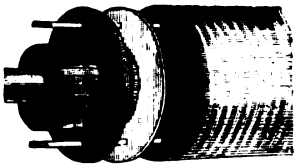

Fig. 2.—Parts of Armature Core.

The series of iron rings is secured to the wooden cylinder and the shaft by two pins passing through the rings, the wooden cylinder, and the shaft. The edges of the end rings are rounded, to prevent them from cutting the insulation of the wires. In two of the rings, at each end of the armature core, are formed 24 equidistant radial slots, *b* (Fig. 3), one-eighth inch deep and one-sixteenth inch wide. The armature core thus formed is covered over its entire surface with adhesive tape, such as is commonly used by wire men for covering joints in conductors. The tape is wound spirally on the periphery of the core, and is arranged radially on the end of the core. It is also wound spirally upon the shaft one and three-eighths inches in each direction from the ends of the armature core. Into the radial slots *b* are driven small wedges, *a*, of hard rubber, which are allowed to project three-sixteenths of an inch beyond the periphery of the core.

The winding of the armature is most readily done in a lathe, as shown in Fig. 3. The armature shaft with a dog attached is supported between the centres of the lathe, with dog in engagement with the face plate. A spool of No. 20 wire* is supported in a convenient position at the back of the lathe, and after bending the end of the wire around one of the wedges, leaving about four inches projecting beyond the wedge, the winding is begun. The wire is carried by one hand along the surface of the armature core and through the space between two wedges at the opposite end of the core, corresponding with the space in which the coil was started. The other hand grasps the face plate of the lathe, and as the wire is carried across the end of the armature core, the face plate is dexterously turned through a half revolution, bringing the opposite side of the core uppermost. The wire is then laid between the two

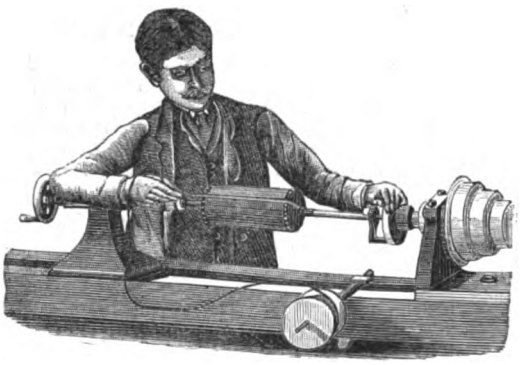

Fig. 3.—Method of Winding.

pairs of wedges diametrically opposite those embracing the wire on the other side of the armature. The wire is carried across the commutator end of the armature core, and the armature is returned to the position of starting by returning the face plate to its first position and the wire is laid alongside of the portion first laid on. The wire is carried lengthwise around the armature in this manner until eight parallel convolutions have been laid on. This layer of wire will extend across the space between two of the wedges. In Fig. 4 the inner layer B is represented as being raised from the core, to more clearly show the position of the wire on the armature, and the inner and outer coils are widely separated ; but it will of course be understood that these

* This quantity varies a few inches with the different coils.

* The wire used is the best cotton covered magnet wire.

Digitized by Google

wires are to lie as closely as possible to the core in the working machine. The beginning or inner terminal E of the coil B is represented in black. In practice this end of the wire is always coated with coloured varnish as soon as the coil is complete, and before the two ends of the coil are twisted together, as they always are temporarily, for convenience in winding, so that there cannot be a mistake as to which are the inner and outer ends of each coil.

After winding the inner layer of the first coil, the winding is continued, forming the outer layer D on top of the inner layer, by winding in the same direction, but returning by the successive coils of the second layer towards the point of starting. When the outer layer is complete the wire is cut, leaving a projecting end about 4in. long. The coloured or inner end of the wire is now twisted with the outer or uncoloured end. In this manner, the first coil is placed in the spaces 1, 1, of the armature. It will be observed by reference to Figs. 4 and 5 that the two halves of each coil are arranged across the end of the armature on opposite sides of the shaft. This secures a compact end and a minimum amount of dead wire.

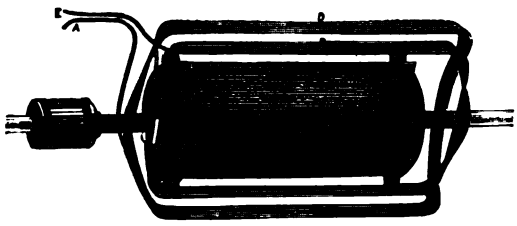

FIG. 4.—First Coil on Armature.

After placing one coil in spaces 1, 1, in the manner described, spaces 2, 2, are filled in the same way, then 3, 3, and so on, until twelve coils are wound upon the core. These coils half fill all of the pairs of spaces 1, 1, 2, 2, 3, 3, &c., to 12, 12, with terminals, A, E, projecting from each space around one-half of the periphery of the commutator end of the armature, the end of the armature presenting an appearance which would be indicated by Fig. 5, if the coils G F were omitted. When the armature is half filled, the winding is continued in exactly the same manner and in the same

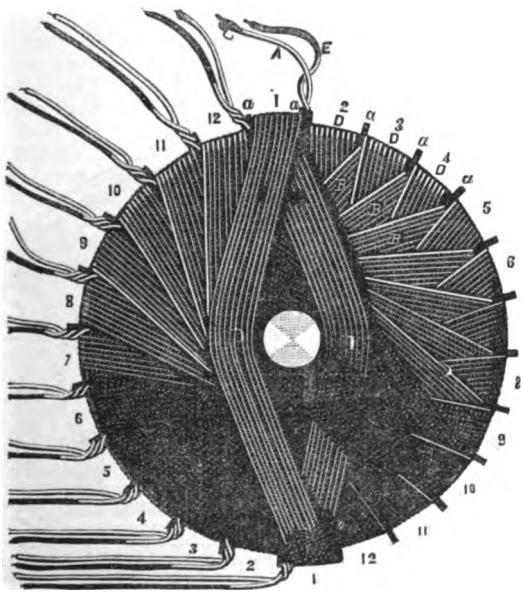

FIG. 5.—Starting the Outer Series of Coils.

direction as before, forming a coil of two layers, F, G, in spaces 1, 1, on top of the first coil B, D, leaving projecting terminals, as in the case of the first series of coils. Then a similar coil is formed on top of the coil in spaces 2, 2, and so on, until each pair of spaces contains two coils, one superposed on the other, every coil being formed of two layers of wire, with eight strands in each layer.

It is advisable, before winding the outer series of coils, to bind the inner series close to the core by a winding of stout linen thread at three equidistant points in the length of the armature. As a guard against the possibility of short-circuiting, the terminals of each coil, where they are in contact with each other or with other portions of the wire, should be provided with an extra wrapping of cotton. The armature thus constructed is known as the Siemens or Hefner-Alteneck armature.

There is another method of constructing the core of the armature which yields good results, but is in some respects inferior to the one described. The armature shaft carries a spool of wood or other non-magnetic material, upon which is wound varnished soft iron wire—the wire being used instead of the iron rings. The commutator cylinder, the method of connecting the terminals of the armature coils with the bars of the commutator cylinder, the brushes, the field-magnet winding, the connections, and other features, remain to be described.—*Scientific American.*

HISTORICAL NOTES ON THE RING DYNAMO WITH INTERIOR MAGNETS.

[The following information has been supplied to us by the London representatives of the firm of Siemens Bros. and Co.]

It not unfrequently happens that while some invention or discovery is being elaborated by the original discoverers, if a short note has been published in a technical journal of the principle involved, others rush at once into print with a description of a similar design, so that when the final work of the originators is fully developed and published, it would appear as though they were the plagiarists, when in point of fact the contrary is the truth. A case in point is the ring dynamo with interior magnets. A description of a dynamo of this type, as manufactured by Messrs. Ganz and Co., of Buda-Pesth, has lately appeared in *Industries*, and any person reading the article would naturally be led to the belief that this firm were the originators of this particular type of dynamo.

Shortly described, the ring dynamo consists of a fixed central electro-magnet, with four limbs at right angles to each other; through the centre of this electro-magnet passes the axle of the external Pacinotti ring, which revolves outside the fixed central magnet. The outside ring is of considerable diameter, and as it entirely surrounds the magnetic field the lines of force must necessarily pass through it. The first continuous-current dynamo of this type with a Pacinotti ring, and with magnets inside the ring only, in the shape of a double T, formed one of the exhibits of Messrs. Siemens and Halske at the Paris Exhibition in 1881. Since that time they have been occupied in developing and perfecting this form of dynamo, and on the 22nd October, 1886, an application was made by them to the German Patent Office. The specification describes the practically completed form of the the ring dynamo with an interior multipolar electro-magnet. The communication with a detailed description and drawings was made public to everyone in the usual way on the 14th January of this year in the *Journal* of the Patent Office. Moreover, in the same month of January the detailed drawings of four large dynamos of this type were submitted by Messrs. Siemens and Halske with their tender for the electric lighting of the Frankfort Central Railway Station, and on the basis of this tender, the contract for the work was awarded to them.

At the meeting of the Berlin Electro-Technical Society, on the 29th March last, a paper was read by Mr. von Hefner-Alteneck on the "Ring Dynamo with Interior Magnets," which paper was subsequently printed in the April number of the *Journal* of the Society. No other publication had been made by Messrs. Siemens and Halske up to that time.

In the number of the *Zeitschrift für Elektrotechnik* (Vienna), of the 1st April, and in that of the *Centralblatt für Elektrotechnik* of the same date, the firm of Messrs. Ganz and Co., of Buda-Pesth, come forward with a dynamo, which, if different in details, is yet in design similar to the ring dynamo, and they state that in 1884 the question occurred to them to construct a dynamo capable of giving the greatest possible output, whilst having the least possible weight.

The *Centralblatt* accompanied this article by a foot note, to which it is desirable to give the widest possible circulation, while reproducing exactly the punctuation:—"Editorial note. The firm of Siemens and Halske is at present engaged in bringing out the same construction!!"

Messrs. Ganz and Co. maintain in the above-mentioned article that their dynamo is the offspring of the alternate current machine of the Zipernowski type, which they have constructed. It might equally well be said that the much older Gramme alternate current machine, which has a Pacinotti ring outside, and electro-magnets inside, is a much nearer parent to their new dynamo. Moreover, the Zipernowski machine, constructed in 1882 or 1883, had a striking family resemblance to the well-known Siemens alternate current machine, as it was modified in the German patent of the 3rd April, 1878, and as it was constructed by Messrs. Siemens and Halske prior to Messrs. Ganz and Co., and shown at the Vienna Exhibition in 1883.

Size of wire on armature, No. 20 Am. W. G.	0·027	in diam.
Length (approximate) of wire in each armature coil*	25	feet.
Number of convolutions in each layer	8	
Number of convolutions in each coil	16	
Number of layers in each coil	2	
Number of coils in each space of the armature	2	
External diameter of armature	3$\frac{3}{8}$	inches.
Weight of wire on armature	2$\frac{1}{2}$	pounds.
Diameter of pulley on armature shaft	3$\frac{1}{2}$	inches.
Width of pulley on armature shaft	2$\frac{1}{2}$	,,
Width of driving belt	2	,,
Size of wire on field-magnet, No. 18 Am. W. G.	0·033	in diam.
Number of parallel wires on each leg of field-magnet	4	
Number of layers of wire on each leg of field-magnet	8	
Number of layers for each wire	2	
Weight of wire on field-magnet	17	pounds.

The field-magnet is made of two like parts of soft, grey cast iron, joined at the centre of the yoke, and bound together by two bolts, as shown in Fig 1. The adjoining surfaces of the yoke are accurately faced, so that when clamped together the connected halves of the magnet will be practically the same as if made integrally.

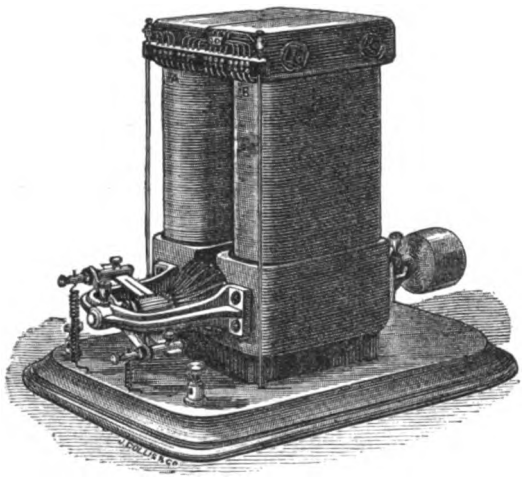

FIG. 1.—Eight-light Dynamo.

The bore of the polar extremities of the magnet is 3$\frac{3}{8}$in. in diameter, and the sides of the magnet around the bore are faced in the lathe to form a true support for the bronze yokes supporting the ends of the armature shaft. These yokes are bored to receive the armature shaft, and faced in the lathe upon the surfaces abutting against the sides of the magnet. The yokes are secured in their places on the magnet with their centres coincident with the axis of the bore of the magnet.

The armature shaft is fitted so as to revolve freely on its bearings, and there is a clearance between the periphery of the armature and the magnet of about $\frac{1}{8}$in. Upon the portion of the armature shaft lying between the poles of the field-magnet is placed the cylinder, of seasoned hard wood of the size above given. Upon this wooden cylinder are placed the thirty-nine iron rings or washers, with intervening paper rings of the same size and about $\frac{1}{32}$in. thick. The iron rings are drilled at diametrically opposite points to receive the brass rods by which the entire series is held together. The arrangement of the parts of the core of the armature is shown in Fig. 2, in which some of the iron rings have been separated, to more clearly illustrate the construction.

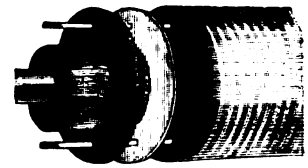

FIG. 2.—Parts of Armature Core.

The series of iron rings is secured to the wooden cylinder and the shaft by two pins passing through the rings, the wooden cylinder, and the shaft. The edges of the end rings are rounded, to prevent them from cutting the insulation of the wires. In two of the rings, at each end of the armature core, are formed 24 equidistant radial slots, *b* (Fig. 3), one-eighth inch deep and one-sixteenth inch wide. The armature core thus formed is covered over its entire surface with adhesive tape, such as is commonly used by wire men for covering joints in conductors. The tape is wound spirally on the periphery of the core, and is arranged radially on the end of the core. It is also wound spirally upon the shaft one and three-eighths inches in each direction from the ends of the armature core. Into the radial slots *b* are driven small wedges, *a*, of hard rubber, which are allowed to project three-sixteenths of an inch beyond the periphery of the core.

The winding of the armature is most readily done in a lathe, as shown in Fig. 3. The armature shaft with a dog attached is supported between the centres of the lathe, with dog in engagement with the face plate. A spool of No. 20 wire* is supported in a convenient position at the back of the lathe, and after bending the end of the wire around one of the wedges, leaving about four inches projecting beyond the wedge, the winding is begun. The wire is carried by one hand along the surface of the armature core and through the space between two wedges at the opposite end of the core, corresponding with the space in which the coil was started. The other hand grasps the face plate of the lathe, and as the wire is carried across the end of the armature core, the face plate is dexterously turned through a half revolution, bringing the opposite side of the core uppermost. The wire is then laid between the two pairs of wedges diametrically opposite those embracing the wire on the other side of the armature. The wire is carried across the commutator end of the armature core, and the armature is returned to the position of starting by returning the face plate to its first position and the wire is laid alongside of the portion first laid on. The wire is carried lengthwise around the armature in this manner until eight parallel convolutions have been laid on. This layer of wire will extend across the space between two of the wedges. In Fig. 4 the inner layer B is represented as being raised from the core, to more clearly show the position of the wire on the armature, and the inner and outer coils are widely separated ; but it will of course be understood that these

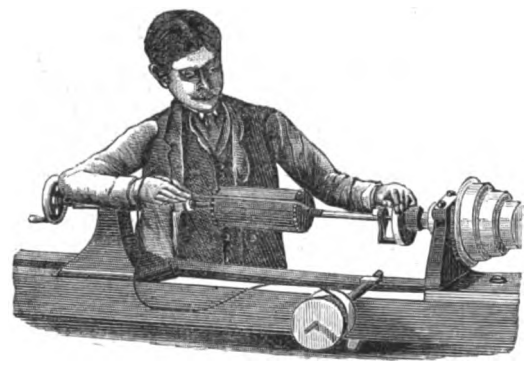

FIG. 3.—Method of Winding.

* This quantity varies a few inches with the different coils.

* The wire used is the best cotton covered magnet wire.

Digitized by Google

wires are to lie as closely as possible to the core in the working machine. The beginning or inner terminal E of the coil B is represented in black. In practice this end of the wire is always coated with coloured varnish as soon as the coil is complete, and before the two ends of the coil are twisted together, as they always are temporarily, for convenience in winding, so that there cannot be a mistake as to which are the inner and outer ends of each coil.

After winding the inner layer of the first coil, the winding is continued, forming the outer layer D on top of the inner layer, by winding in the same direction, but returning by the successive coils of the second layer towards the point of starting. When the outer layer is complete the wire is cut, leaving a projecting end about 4in. long. The coloured or inner end of the wire is now twisted with the outer or uncoloured end. In this manner, the first coil is placed in the spaces 1, 1, of the armature. It will be observed by reference to Figs. 4 and 5 that the two halves of each coil are arranged across the end of the armature on opposite sides of the shaft. This secures a compact end and a minimum amount of dead wire.

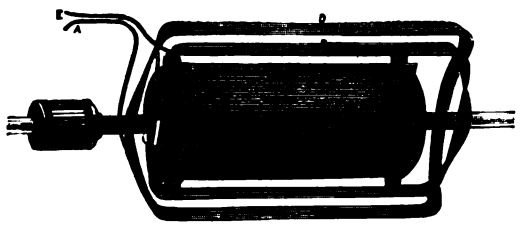

FIG. 4.—First Coil on Armature.

After placing one coil in spaces 1, 1, in the manner described, spaces 2, 2, are filled in the same way, then 3, 3, and so on, until twelve coils are wound upon the core. These coils half fill all of the pairs of spaces 1, 1, 2, 2, 3, 3, &c., to 12, 12, with terminals, A, E, projecting from each space around one-half of the periphery of the commutator end of the armature, the end of the armature presenting an appearance which would be indicated by Fig. 5, if the coils G F were omitted. When the armature is half filled, the winding is continued in exactly the same manner and in the same

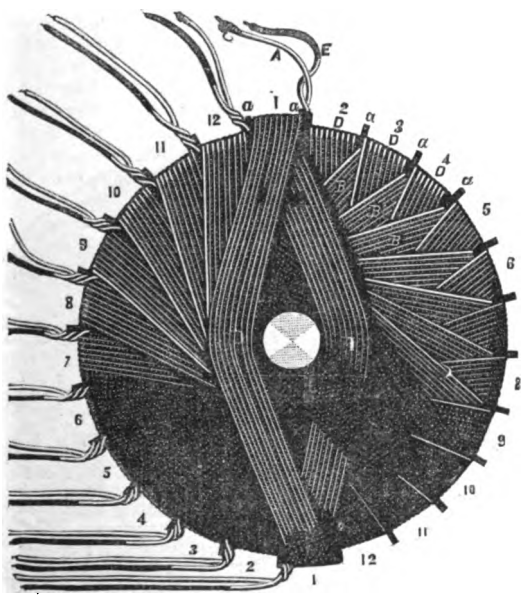

FIG. 5.—Starting the Outer Series of Coils.

direction as before, forming a coil of two layers, F, G, in spaces 1, 1, on top of the first coil B, D, leaving projecting terminals, as in the case of the first series of coils. Then a similar coil is formed on top of the coil in spaces 2, 2, and so on, until each pair of spaces contains two coils, one superposed on the other, every coil being formed of two layers of wire, with eight strands in each layer.

It is advisable, before winding the outer series of coils, to bind the inner series close to the core by a winding of stout linen thread at three equidistant points in the length of the armature. As a guard against the possibility of short-circuiting, the terminals of each coil, where they are in contact with each other or with other portions of the wire, should be provided with an extra wrapping of cotton. The armature thus constructed is known as the Siemens or Hefner-Alteneck armature.

There is another method of constructing the core of the armature which yields good results, but is in some respects inferior to the one described. The armature shaft carries a spool of wood or other non-magnetic material, upon which is wound varnished soft iron wire—the wire being used instead of the iron rings. The commutator cylinder, the method of connecting the terminals of the armature coils with the bars of the commutator cylinder, the brushes, the field-magnet winding, the connections, and other features, remain to be described.—*Scientific American.*

HISTORICAL NOTES ON THE RING DYNAMO WITH INTERIOR MAGNETS.

[The following information has been supplied to us by the London representatives of the firm of Siemens Bros. and Co.]

It not unfrequently happens that while some invention or discovery is being elaborated by the original discoverers, if a short note has been published in a technical journal of the principle involved, others rush at once into print with a description of a similar design, so that when the final work of the originators is fully developed and published, it would appear as though they were the plagiarists, when in point of fact the contrary is the truth. A case in point is the ring dynamo with interior magnets. A description of a dynamo of this type, as manufactured by Messrs. Ganz and Co., of Buda-Pesth, has lately appeared in *Industries*, and any person reading the article would naturally be led to the belief that this firm were the originators of this particular type of dynamo.

Shortly described, the ring dynamo consists of a fixed central electro-magnet, with four limbs at right angles to each other; through the centre of this electro-magnet passes the axle of the external Pacinotti ring, which revolves outside the fixed central magnet. The outside ring is of considerable diameter, and as it entirely surrounds the magnetic field the lines of force must necessarily pass through it. The first continuous-current dynamo of this type with a Pacinotti ring, and with magnets inside the ring only, in the shape of a double T, formed one of the exhibits of Messrs. Siemens and Halske at the Paris Exhibition in 1881. Since that time they have been occupied in developing and perfecting this form of dynamo, and on the 22nd October, 1886, an application was made by them to the German Patent Office. The specification describes the practically completed form of the the ring dynamo with an interior multipolar electro-magnet. The communication with a detailed description and drawings was made public to everyone in the usual way on the 14th January of this year in the *Journal* of the Patent Office. Moreover, in the same month of January the detailed drawings of four large dynamos of this type were submitted by Messrs. Siemens and Halske with their tender for the electric lighting of the Frankfort Central Railway Station, and on the basis of this tender, the contract for the work was awarded to them.

At the meeting of the Berlin Electro-Technical Society, on the 29th March last, a paper was read by Mr. von Hefner-Alteneck on the "Ring Dynamo with Interior Magnets," which paper was subsequently printed in the April number of the *Journal* of the Society. No other publication had been made by Messrs. Siemens and Halske up to that time.

In the number of the *Zeitschrift für Elektrotechnik* (Vienna), of the 1st April, and in that of the *Centralblatt für Elektrotechnik* of the same date, the firm of Messrs. Ganz and Co., of Buda-Pesth, come forward with a dynamo, which, if different in details, is yet in design similar to the ring dynamo, and they state that in 1884 the question occurred to them to construct a dynamo capable of giving the greatest possible output, whilst having the least possible weight.

The *Centralblatt* accompanied this article by a foot note, to which it is desirable to give the widest possible circulation, while reproducing exactly the punctuation:—"Editorial note. The firm of Siemens and Halske is at present engaged in bringing out the same construction!!"

Messrs. Ganz and Co. maintain in the above-mentioned article that their dynamo is the offspring of the alternate current machine of the Zipernowski type, which they have constructed. It might equally well be said that the much older Gramme alternate current machine, which has a Pacinotti ring outside, and electro-magnets inside, is a much nearer parent to their new dynamo. Moreover, the Zipernowski machine, constructed in 1882 or 1883, had a striking family resemblance to the well-known Siemens alternate current machine, as it was modified in the German patent of the 3rd April, 1878, and as it was constructed by Messrs. Siemens and Halske prior to Messrs. Ganz and Co., and shown at the Vienna Exhibition in 1883.

THE MICRO-TELEPHONE PUSH-BUTTON OF DR. CORNELIUS HERZ.

This apparatus, says *La Lumière Electrique*, is a revised and augmented edition of the telephone push-button of the same inventor. In addition

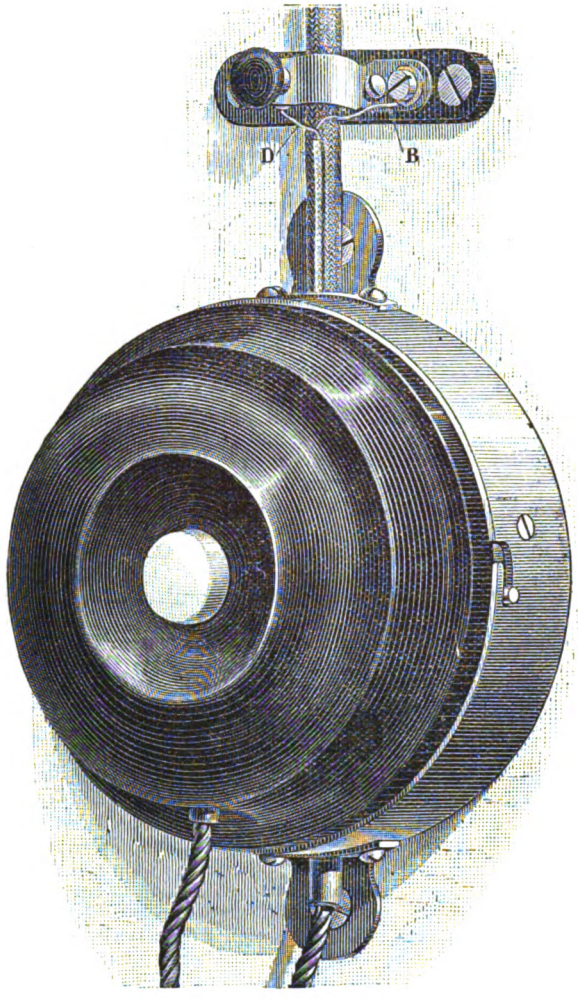

FIG. 1.

to the bell contact, automatic accumulator and telephone, serving alternately as transmitter and as receiver of the latter-mentioned instrument,

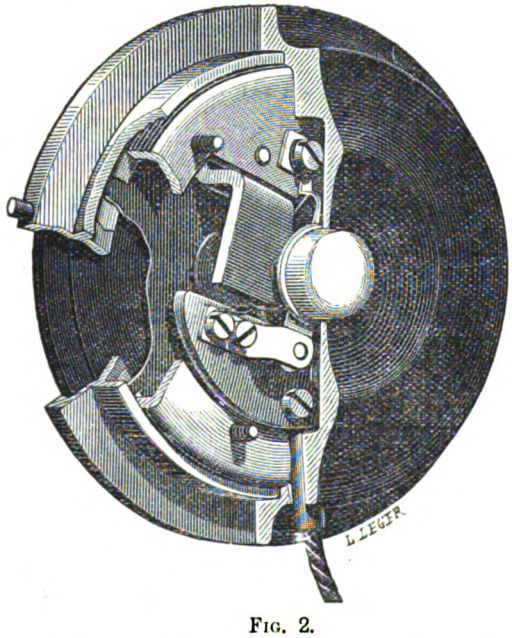

FIG. 2.

the micro-telephone push-button, which is also intended mainly for domestic use and private installations, includes a microphonic transmitter

It constitutes in itself a complete set of telephone apparatus for a station, with the exception of the battery, whilst providing at the same time an

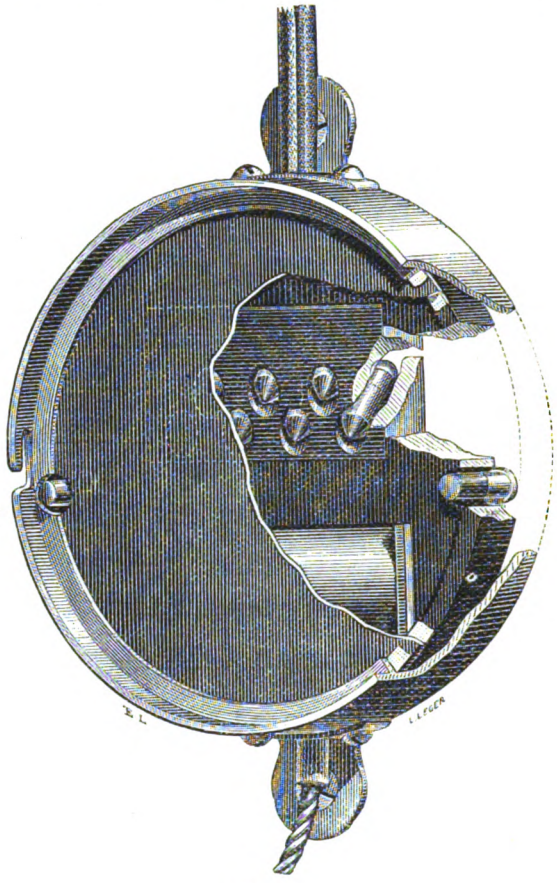

FIG. 3.

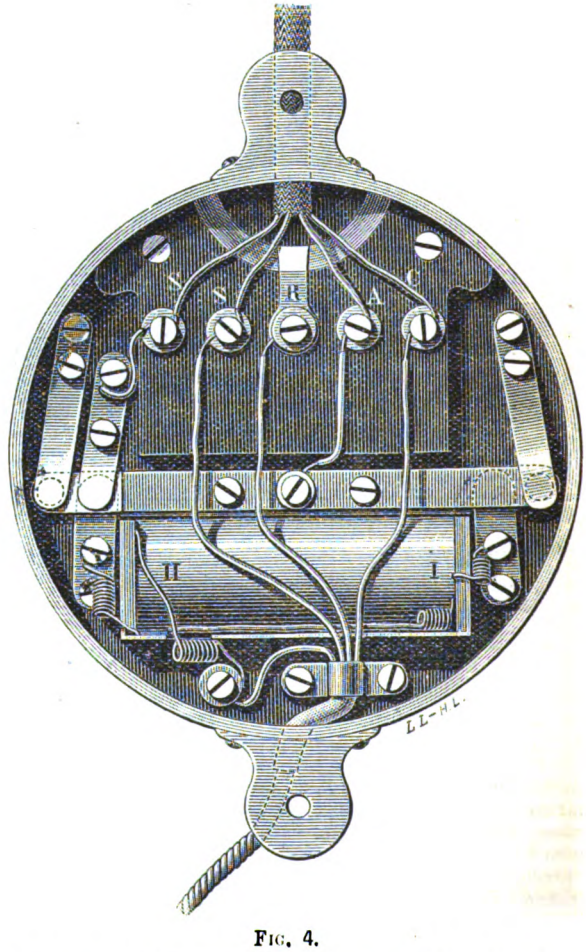

FIG. 4.

electric bell system. The object of the present article is to show that with

Digitized by Google

stations of this kind and a central battery the current can be utilised for working the microphones at the different stations, and that communication can be established at will between the different apparatus either through the intermediary of a central station or without such intermediary.

Fig. 1 is a full-sized view of the apparatus to be attached to the wall or doorpost of a room. It is composed of two parts, one which is fixed, containing the microphone and the automatic commutator, the other, which is movable, containing the telephonic receiver and the bell-push, the two portions being connected by a flexible conductor.

Fig. 2 represents the movable part of the telephone contact button alone. Figs. 3 and 4 show a front and back view of the fixed portion, with two holes through which project two little nipple contacts, which operate the automatic switch. In order to understand the action of this automatic switch, of which the different portions are placed, as shown in Fig. 4, on the back portion of the stand, it will be well to refer to Fig. 5, which shows the connections between two micro-telephonic stations, worked by a single battery.

The commutator is formed by an elastic rod of brass, T, placed horizontally on the front part of the apparatus, and which is moved forward by the nipple contacts when the telephone button is unfastened, and which is moved backwards when this is replaced on its stand.

In regard to Fig. 5, we will suppose that Station No. 1 calls to Station

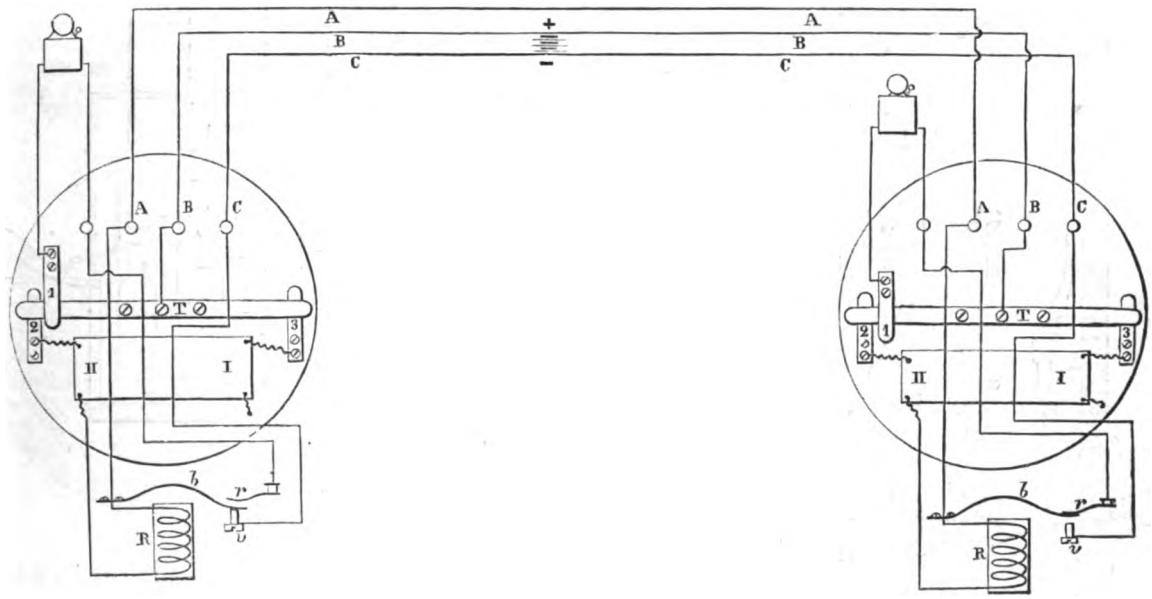

FIG. 5.

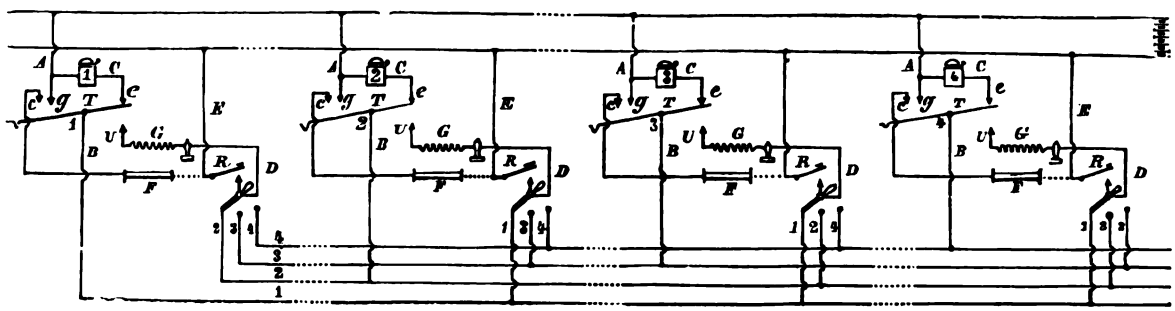

FIG. 6.

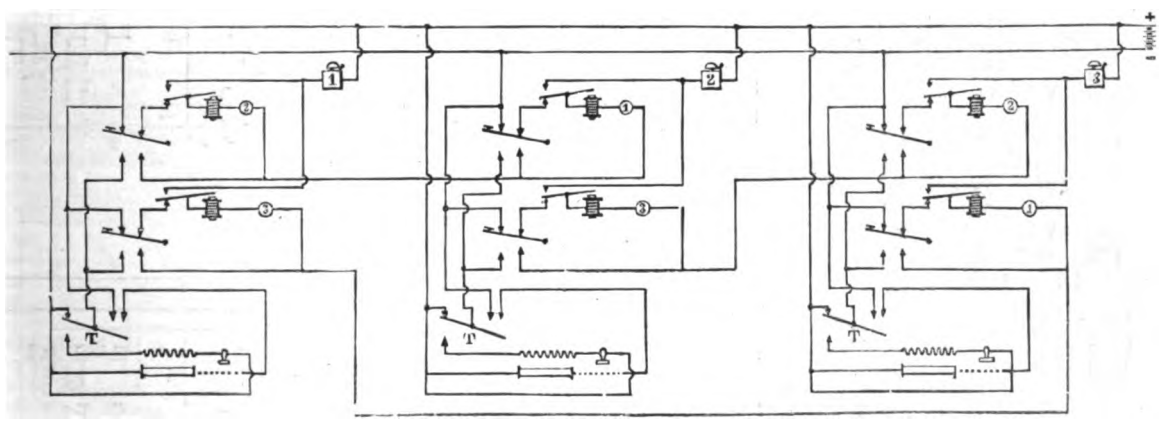

FIG. 7.

including, as we have said, the microphone, the induction coil, and the automatic commutator. Fig. 3 explains the construction of the microphone, which is formed of a carbon diaphragm 2 millimetres in thickness placed at a distance of 1 5 millimetre from the block, which is also of carbon, the variable resistance of the contact being formed by a group of small pencils of carbon, movable within inclined apertures. The positive ends of these pencils bear against the diaphragm, being pressed in contact with it by the effect of their own weight and that of small leaden balls placed above them.

On the carbon block just mentioned is placed the induction coil. The carbon plate is perforated at opposite ends of its horizontal diameter

No. 2. The push-button (Fig. 1) is pressed inwards, thus bringing the spring *b* (Station 1) against the screw *v*, thus breaking contact *r*, so as to put the bell of Station 1 out of circuit, and close the circuit of the battery through the bell of Station 2.

It is easy to see that we have a closed circuit starting from the positive pole of the battery and through the wire B, the commutator T, the Station 2, contacts I, the ball, the springs *r* and *b* of this same station, and returning to the negative pole of the battery through the wire A, the spring *b*, the screw *v* of Station 1, and the wire C.

When the telephone button is removed the ball is placed out of circuit by the motion of the commutator T, which breaks contact with *i* and

Digitized by Google

establishes contact with the springs 2 and 3, thus closing the primary circuit and the secondary circuit of the induction coil, 1 and 2. The primary circuit is established as follows:—From the positive pole of the battery to the wire *b*, the commutator T, and the contact spring 3, then through the coil, of which the other end is connected with the carbon diaphragm. From this diaphragm the circuit is completed by the variable resistance contacts and the wire *c*, which communicates with the negative pole of the battery.

It will be seen that, according to this arrangement the primary and the

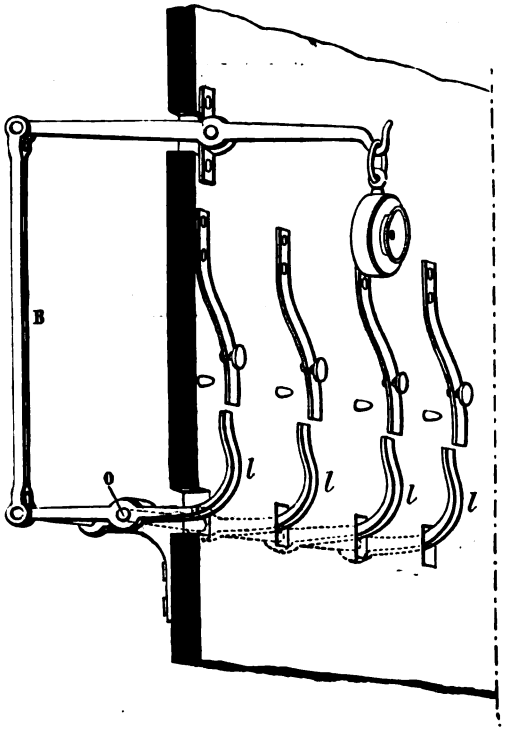

FIG. 8

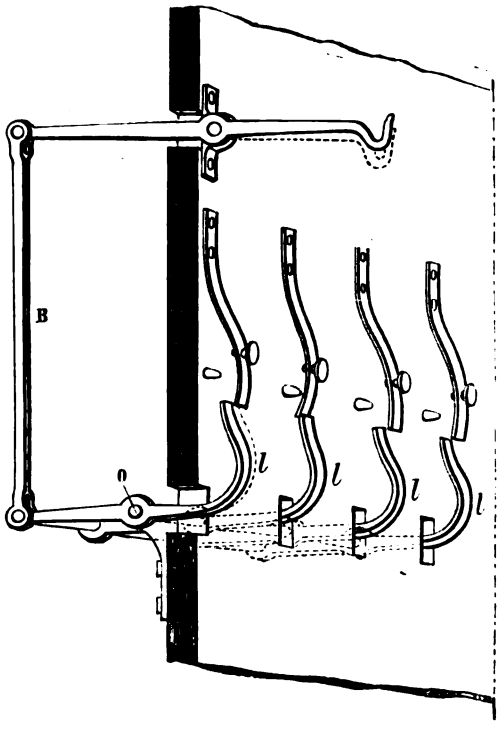

FIG. 9.

secondary circuits have one position in common, which position is represented by the wire B. This is an arrangement much used in America, allowing wire to be economised, and not offering any disadvantage. The play of the commutator T is ensured by the mode of attaching together the movable and fixed portions of the micro-telephone button. As is shown in Fig. 1, the two portions are fastened together by means of a bayonet joint.

The advantages exhibited in Fig. 5 are very simple, representing a case which would but rarely occur in practice. Practically, there would almost always be a certain number, *n*, of stations which would have to be connected together and with a single battery in such a manner that each station would be able to call either of the others. The problem to be solved admits of several solutions, some of which are explained at considerable length in the article by our contemporary. Thus, for instance, Fig. 6 applies to the case in which a central station is out of the question. Here T represents the automatic switch, F the microphone and the primary

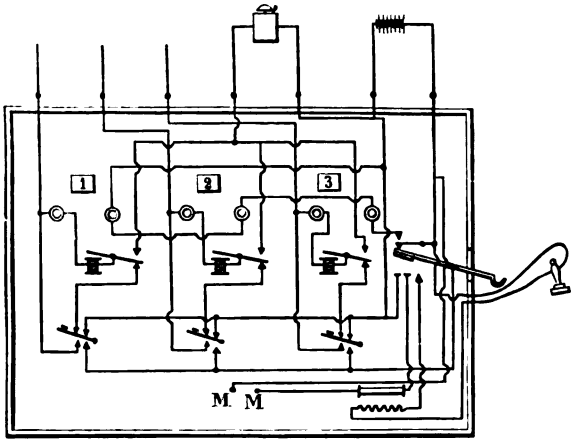

FIG. 10.

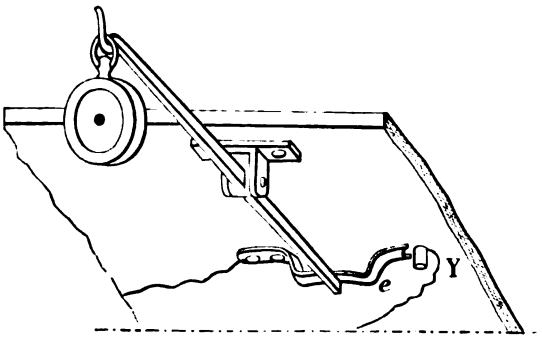

FIG. 11.

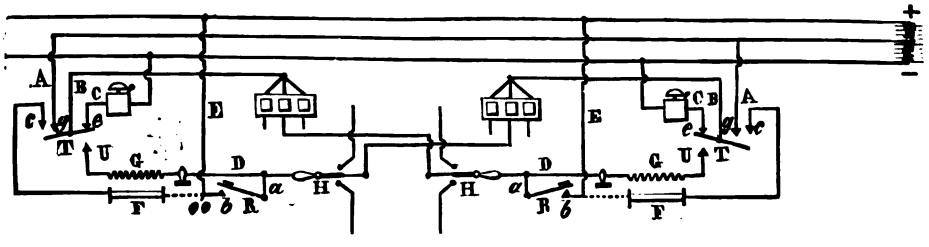

FIG. 12.

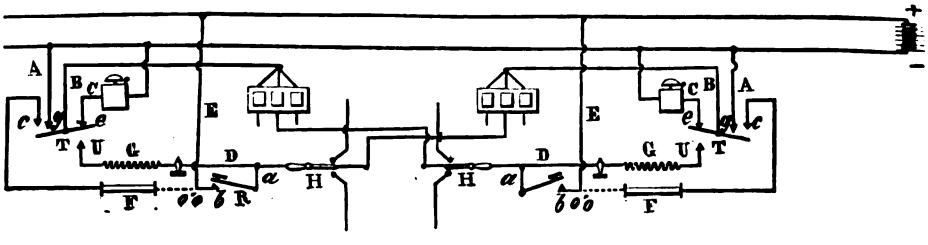

FIG. 13.

circuit of the induction coil, G the secondary circuit of the coil, R the call push, and D a switch having $n-1$ branches for a given number, *n*, of stations. If it is required that each station should be informed by means of an annunciator as to the locality whence the call comes, then the installation represented in Fig. 7 becomes somewhat more complicated. The switch T is still in its position, but instead of the single push of the micro-telephonic button we have as many contact pushes as there are lines,

Digitized by Google

less one. The lines are connected to an annunciator through a small electro-magnet, the armature of which closes the circuit of the bell when the current passes. This prevents the bells of the other stations ringing when any one calls another. A single electro-magnet can, however, be used, around which would be placed all the coils of wire corresponding to the different lines. When the push call is pressed the circuit of its own bell is opened, and the number of its annunciator corresponding to the station to be called is short-circuited in order not to show the number there.

The commutator T acts as before, but the push must be kept down all the time the conversation lasts.

Figs. 8 and 9 show a plan for keeping down the pushes during conversation, and for raising them afterwards. The commutator T commands by means of B a series of elbowed levers *l*, movable about a common axis *o*. When the telephone is hooked the levers *l* allow of sounding freely, but when the telephone is unhooked the levers prevent the raising of the lowered buttons, or lowering of those which are up. On re-hooking the telephone after speaking this locking is undone, the numbers are returned, and the apparatus is placed in the waiting position. This plan requires (and this is the drawback to the system) $n\left(\frac{n-1}{2}\right)+2$ wires for n stations, a number increasing rapidly with the value of n. When the number of stations is quite small they can be connected two by two, a plan necessitating $n(n-1)+3$ or $n(n-1)+2$ wires, according as the microphones are capable of supporting a fraction of the current (Fig. 12), or that of the whole battery (Fig. 13).

Fig. 10 shows the arrangement of an automatic microphonic station on this system. The terminals M M are those which are connected with the microphone wires. The contact Y, Fig. 11, serves to replace the numbers which have been exposed. The clutch *c* of the telephone hook is a spring fixed on one side only, which does not come into contact with Y by the weight of the telephone alone, although by a slight pressure when the telephone is hooked up after a conversation the circuit of the recall coils is momentarily closed, and the numbers drawn out thus replaced.

(*To be continued.*)

MODES OF MEASURING THE CO-EFFICIENTS OF SELF AND MUTUAL INDUCTION.*

By Profs. W. E. Ayrton, F.R.S., and John Perry, F.R.S., Members.

This paper does not resemble Prof. Hughes's inaugural address, in containing a charming account of new experimental researches into the laws of self-induction and of the extra resistance offered to a rapidly-varying current. Its aim is different, it is meant to help the practical electrician to obtain as clear a conception of self-induction as he now has of resistance, and to this end the paper contains the description, and theory of the action, of a simple apparatus that we devised a year ago, and which we have been since improving, for the *direct* measurement of the coefficients of self and of mutual induction in terms of the legal unit.

The electrician of to-day is so familiar with the idea of resistance, that he is liable to forget the time when people had no clear conception that the resistance of a conductor was one of its definite properties, like its weight and length. In the "Reports of the Committee on Electrical Standards," edited by the late Prof. Fleeming Jenkin, a most interesting account is given of the gradual growth of the conception that a conductor had a definite resistance; and in our paper on "A New Determination of the Ratio of the Electromagnetic to the Electrostatic Unit of Electrical Quantity," read before this society in 1879, something is said about the development of this idea of resistance. And during the fifty years that have elapsed since Lenz employed the one foot of No. 11 copper wire as his unit of resistance, the electrical world has not only learnt to regard resistance as a definite property of a definite piece of matter in a definite state, but has become so fully imbued with this idea, that it positively resented Prof. Hughes' experimental proof, last year, that the resistance of a conductor for an intermittent current was a variable.

Now, how has this clear perception about resistance been acquired? We believe by the measuring of hundreds of thousands of resistances during the last twenty-two years in terms of a unit of resistance with a simple name; and we feel that it will not be until many measurements of the coefficients of self-induction of various coils, electro-magnets, dynamos, &c., have been made by practical men, as part of their regular work, and expressed in a unit of self-induction having a simple name, that they will come to have the same instinctive feeling about self-induction that they now have about resistance. There are two reasons why such measurements have not been regularly made; one is, that the importance of a knowledge of the coefficient of self-induction of a circuit is only beginning to be generally appreciated; the other, that the methods of measuring the coefficient have not been very easy to employ. But now that the speed of telegraph signalling is becoming greater and greater, that long-distance telephony is receiving more and more attention, and that the system of distributing electrical energy with secondary generators and alternating currents has become a most important rival to other systems, the regular measurement of the coefficients of self and of mutual induction of dynamos, electro-magnets, induction coils, &c., has now become quite as important to the electrical engineer as the measurement of resistance.

Prof. Hughes' telephone methods for comparing the self-induction of one circuit with that of another are marvellously sensitive, as shown by the results he obtained, but the very delicacy of the methods prevents their being used without a compensator or adjustable standard of mutual induction for the commercial measurement of a coefficient of self-induction in terms of the product of a time into a resistance.

On turning to the electrician's "stand-by," Clerk-Maxwell, one finds a complete exposition of the general principles of self-induction, also several methods for determining what he calls "the electro-magnetic capacity of self-induction of a coil." The very length of the name makes one fear that the methods will be impracticable for every-day work, and that is the case; for the only one which is suited to a practical man, as far as the apparatus is concerned, is unsuitable from a difficulty met with in carrying it out. The method in question is called "comparison of the electrostatic capacity of a condenser with the electromagnetic capacity of self-induction of a coil,"* and the result expresses the coefficient of self-induction as equal to the product of two resistances into the capacity of a condenser. A number of attempts to employ this method were made rather more than a year ago by one of our students, Mr. Sumpner, but the necessity of having to make two separate adjustments of the resistances of the Wheatstone bridge, one in order that there should be no deflection of the galvanometer for steady currents in the arms, the other that there should be no deflection on making or breaking the battery circuit, and the fact that altering the resistances to make either of these adjustments generally disturbed the other adjustment previously made, rendered the method nearly hopeless.

If not merely the resistance of the arms of the bridge were adjustable, but also the capacity of the condenser, so that it might be made to have different known values, this method might give good results if a galvanometer with a long periodic time of vibration were employed. If, however, an ordinary bridge galvanometer were used, the difference that exists in the rate of charging of a condenser and the rate of variation of the extra current due to self-induction would make it impossible for the resistances and the capacity of the condenser to be generally adjusted, so that there was no deflection of the galvanometer on making and breaking the battery circuit, as there would first be a deflection on one side of the zero, then on the other, consequently a very accurate measurement of the coefficient of self-induction could not be made. Modifications of this method, by combining resistances and one or more condensers with a differential galvanometer, have been suggested and tried with more or less good results, but, as explained later on, with none of these methods can the effect be made *cumulative*, and the test therefore very sensitive, by using the plan of rapidly making and breaking the battery circuit.

Probably the best method yet published for measuring the coefficient of self-induction in terms of the product of a time into a resistance is that described by Lord Rayleigh in his paper on "Experiments to Determine the Value of the British Association Unit of Resistance in Absolute Measure," given in *Philosophical Transactions* for 1882, and abstracted by one of us for the *Journal* of the Society, where it will be found on page 152 of the volume for that year. This method, based on one devised by Clerk-Maxwell, but not described in either the first or second edition of his book, consists in placing the coil with self-induction in one of the arms of a Wheatstone bridge, and first obtaining balance in the ordinary way, the battery circuit being completed *before* the galvanometer circuit, then measuring the swing of the galvanometer needle when the battery circuit is completed *after* the galvanometer circuit, and lastly measuring the steady deflection obtained when one or more of the arms of the bridge is altered by a known amount, the battery circuit being completed before the galvanometer circuit, as in the first test.

This method is simple, but it has three great disadvantages. First, while an ordinary Wheatstone bridge is employed, an ordinary dead-beat Wheatstone bridge galvanometer is totally unsuitable, since on making or breaking the battery circuit, when performing the second test, the galvanometer needle must not begin to move until the extra current has ceased; and further, the time of vibration of the galvanometer needle, and the logarithmic decrement, have to be determined, as they both enter into the formula, so that, in fact, a ballistic galvanometer must be employed. Second, if the coefficient of self-induction to be measured be small, the swing of the galvanometer needle obtained on making or breaking the battery circuit will be very small, and cannot be accurately read. And the effects cannot be made *cumulative* by rapidly making and breaking the battery circuit when using either this method or the one described in Clerk-Maxwell, referred to above, or any simple modification of these methods, since the swings of the galvanometer needle are in opposite directions on making and on breaking the battery circuit. Third, in making the first test with the Wheatstone bridge a *very accurate* balance must be obtained, since the swing obtained on making the second test must be *entirely* due to the effect of self-induction. Consequently a sliding wire in addition to the ordinary bridge must be employed, instead of using the simple interpolation method of obtaining the last decimal place from the small steady deflections to the right and left of the true zero. *(See Appendix II.)*

* Paper read before the Society of Telegraph-Engineers and Electricians on April 28th, 1887.

* A student might naturally conclude that, as a capacity measured *electrostatically* is of the same dimensions as a coefficient of self-induction measured *electromagnetically*, both being a simple length, it was this comparison that Clerk-Maxwell referred to; but that is not the case, as shown by the working out of the problem, consequently the answer contains the square of a resistance in addition to the capacity of the condenser and the coefficient of self-induction of the coil. Hence the problem is not strictly the comparison of the electrostatic capacity of a condenser with the electromagnetic capacity of self-induction of a coil.

Digitized by Google

A circuit containing self-induction acts as if it had a larger resistance than its true one when a current is started in it, and a smaller resistance when the current is stopped. Hence, if balance be obtained with a Wheatstone bridge in the ordinary way, the fact of any of the arms possessing self-induction, or of any one of the arms having a condenser attached to it, will produce no effect on the balance if the battery circuit be rapidly made and broken, provided that the rapidity of make and break be not too great for the currents in the arms of the bridge to reach their steady values each time that the battery circuit is made, and to die away each time that it is broken. If the currents have not time to reach their steady value when the battery circuit is closed, and to die away when it is broken, then self-induction in any one of the arms will produce a disturbance in the balance; but such a method of measuring a coefficient of self-induction would lead to very complicated formulæ, and is not worth developing with the view of obtaining a simple method of measuring self-induction.

It therefore occurred to us to consider whether, without employing such rapid makes and breaks as would prevent the currents reaching their steady values, the self-induction of a circuit might not be made to act as an apparent steady definite increase of the resistance of that circuit which could be measured in the ordinary way with a Wheatstone bridge or differential galvanometer, and by this means the measurement of a coefficient of self-induction would simply resolve itself into the measurement of a resistance. And this problem we solved in the following way, in the spring of 1886:—

The coil, the coefficient of self-induction of which it is desired to measure, is placed in one of the arms of a Wheatstone bridge, the three other arms consisting of ordinary doubly-wound resistance coils possessing no appreciable self-induction, and not only is the battery circuit rapidly made and broken, but, in addition, after each closing of the battery circuit the galvanometer circuit of the bridge is either short-circuited or broken, so as to cut out the galvanometer, and after each breaking of the battery circuit the galvanometer circuit is either unshort-circuited or closed again, so that the galvanometer is now operative again. In this way all the successive impulses of the galvanometer needle that are produced on starting the current in the coil with self-induction produce their *cumulative* effects, but the successive impulses of the needle that, under ordinary circumstances, would be produced on the needle in the opposite direction are cut out. Hence the self-induction possessed by one of the arms causes that arm to apparently increase in resistance by a definite amount depending on the coefficient of self-induction and the number of operations performed per minute. This apparent increase of resistance produces a deflection of the galvanometer which can be noted, and its value ascertained by comparing it with the deflection produced with steady currents when one or more of the arms of the bridge is altered by a known amount, as in making the Rayleigh test described above. But since the necessity of having to read the deflection limits the speed of performing the double make and break operation, in order that the spot of light may not be sent off the scale, we soon replaced this comparative deflection *cumulative* method* by a much more sensitive *zero cumulative* method, and instead of reading the galvanometer deflection we re-establish the balance and bring the needle back to zero, by altering one or more of the arms of the bridge, as in making an ordinary resistance test with a Wheatstone bridge.

In our experiments we have also preferred the periodical short-circuiting of the galvanometer to breaking the galvanometer circuits, since, as there is a current flowing in the galvanometer when this operation is performed if the zero method be employed, the breaking of the galvanometer circuits would produce a spark which would make the calculations difficult, whereas, as will be seen, the periodical short-circuiting of the galvanometer produces an effect that can easily be taken into account in the mathematical investigation.

The measurement of a coefficient of self-induction in this way is extremely simple, because on the condition that the periodic time of our operation is not too short for the currents to become steady in the interval between the closing of the battery circuit and the short-circuiting of the galvanometer, and to die away in the interval between the breaking of the battery circuit and the unshort-circuiting of the galvanometer, we have shown that the following *remarkably simple* formula is very approximately true:—

$$L = T\sigma \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where L is the coefficient of the self-induction of the coil in ohm seconds, or earth quadrants, the commercial unit of self-induction, T the time in any one operation that the galvanometer is non short-circuited while the battery circuit is closed, and σ the apparent increase of resistance of the coil in ohms. It will be observed that when L is small the measured increase of resistance, σ, may be made quite large enough to be accurately measured by making T small. This may be done either by performing the operation rapidly, or, as will be seen later on, by altering the adjustment in the particular apparatus which automatically performs the required operation. *Hence this method is an extremely delicate one for the absolute measurement of a coefficient of self-induction, and the coefficient is expressed in its simplest possible form, namely, as the product of a time into a resistance.*

If instead of periodically cutting out the galvanometer circuit while the battery circuit is being broken, we cut it out while the battery current is being made, and allow the galvanometer to be operative while the battery circuit is being broken, the resistance of the coil possessing self-induction will apparently become less by a definite amount, and in this case σ will be the apparent diminution of its resistance, and T is the time the galvanometer is operative after the battery circuit is broken.

The first apparatus for enabling measurements of self induction to be made in this way was constructed in the spring of 1886, under the superintendence of one of our assistants, Mr. Mather. It consisted of a double commutator, shown in Fig. 1, the spindle S, to which the commutators were locked by the nut N, being rotated at any speed by a small electromotor not shown in the figure, to which was attached a Young speed indicator, which registered the speed of rotation at any moment. The brushes, B_1, B_2, b_1, b_2, were fixed to the baseboard and joined to the bridge, as indicated in the figure. When the double commutator was rotated by the motor (of which the speed was correctly adjusted by means of a Varley flexible carbon-resistance), the portion A B caused the battery circuits to be periodically made and broken, while the other portion, C D, periodically short-circuited and unshort-circuited the galvanometer, so that the following cycle of operation, called for simplicity *one operation*, was performed any desired number of times per minute.

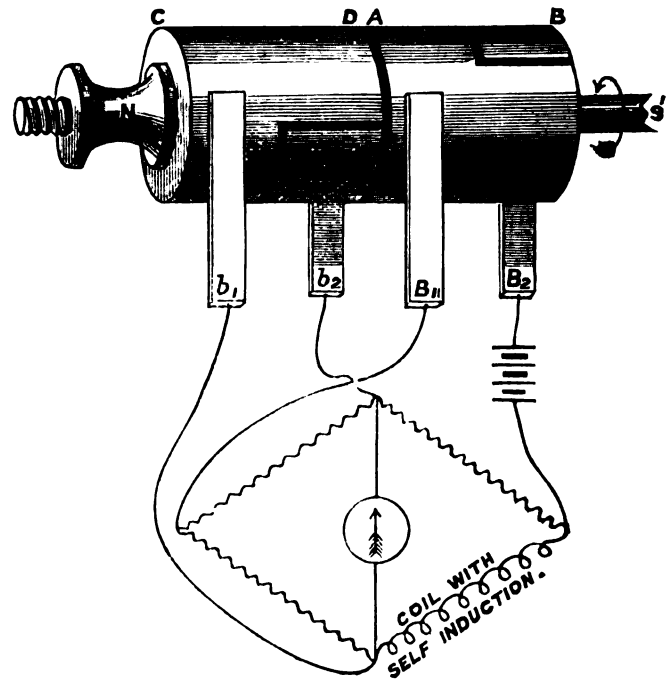

FIG. 1.

Battery Circuit.	Galvanometer Short Circuit.
Make.	While broken.
While made.	Make.
Break.	While made.
While broken.	Break.
Make.	While broken.

The time T in the formula given above is the interval that elapses in one rotation between the time when the continuous part of the commutator A B comes into contact with the brush B_2, and the time when the continuous part of the commutator C D comes into contact with the brush b_2. This time can be made shorter or longer by varying the speed of rotation, but it can also be varied by loosening the nut, N, and shifting one of the commutators round relatively to the other, and then screwing up the nut again. Indeed, it was for the purpose of enabling this adjustment to be easily made that double springs were in each case employed, instead of making one contact through the spindle.

At about this time—that is, in the summer of last year—we invited Mr. Sumpner, one of the third year students of the Central Institution, to experiment with this apparatus, and generally, by experimenting and by working at the subject mathematically, to find out the capabilities of this new method of measuring self-induction, also to see whether by possibly using the apparatus in some other way the method could be made even still more sensitive. We take this opportunity of thanking Mr. Sumpner for the energetic way in which he has worked at the subject, and for the very large number of experiments on the accuracy of various modes of measuring self-induction which he has conducted, with the occasional aid of two other of the third year students, Messrs. Rossiter and Watney.

* Since this paper was announced to be read, M. Lipmann has communicated to the French Academy a paper "Sur la Détermination du Coefficient du Self-induction," by MM. P. Ledeboer and G. Maneuvrier, describing a new method which these experimenters have devised. An examination of it, however, shows that it is identical with our *less sensitive* 1886 method. After giving some very accurate results that they have obtained by using the new method of testing, they say:—"Nous l'avons préferée d'ailleurs aux autres méthodes pour le mésure des faibles coefficients de self-induction, et notamment à la méthode de M. H. F. Weber (modification de celle de M. Hughes), parce qu'elle conduit à une formule très simple et qu'elle nécessite, en dehors du pont du Wheatstone, d'autre disposatif expérimental qu'un interrupteur tournant."

Digitized by Google

The various methods of testing which Mr. Sumpner has employed, the mathematical development of the formulæ used by him in each case, and his general conclusions as to the accuracy of the various methods, are given later on in the Appendix; but one interesting result that he has arrived at may here be mentioned, viz., that although the apparatus has during the past twelve months been gradually totally altered in detail, the experiments have shown that the principle originally proposed for carrying out the measurement, requiring the cycle of operations given in the foregoing table to be periodically and rapidly performed, is the simplest and most accurate one to employ. One reason for the accuracy of the method is that neither commutator is in any one of the arms of the bridge, so that no ordinary change in the resistance of the contacts produced by oil or dust, &c., getting in between the springs and the rotary barrels can introduce any error into the test. Of course an actual failure of contact might lead a careless experimenter to a wrong result, but so might a disconnection in the battery or galvanometer circuit in an ordinary Wheatstone bridge, if the conclusion was drawn that, because there was no deflection on pressing down the key, balance had been obtained.

The first thing to be done after constructing the apparatus, was to ascertain what was the formula connecting the unknown coefficient of self-induction with the apparent increase of resistance of the coil, and the time in which the cycle of operations was performed.

This formula we calculated ourselves, neglecting the self-induction of the galvanometer, since we felt that its effect could not be serious. Mr. Sumpner, on the other hand, took up the complete problem, and we give his proof reduced to its simplest form, since, in addition to its application to the experiment in question, the calculation is interesting in connection with the problem of measuring the capacity of a condenser with a Wheatstone bridge and vibrating wippe, which will be found worked out by Clerk-Maxwell, without, however, any notice being there taken of the self-induction of the galvanometer, the effect of which, therefore, on the answer is not considered.

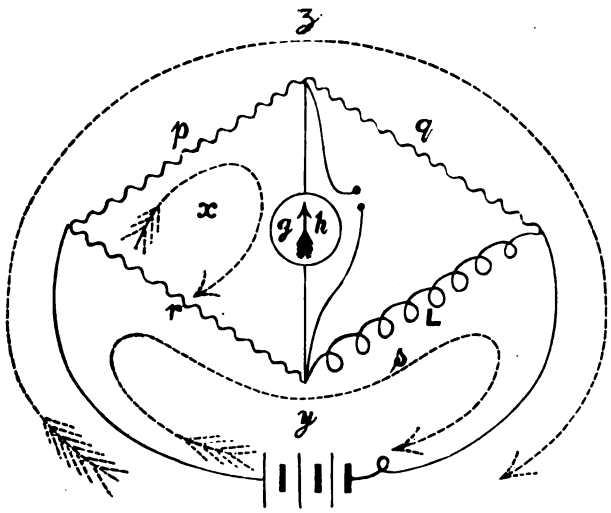

FIG. 2.

Fig. 2. shows the Wheatstone bridge, s being the resistance of a coil with a coefficient of self-induction L; p q and r are the resistances of the three other arms of the bridge when they are so adjusted that there is no deflection of the galvanometer on rotating the commutators at a certain speed. On rotating the commutators a current will sometimes pass one way through the galvanometer and sometimes the other, but with the particular speed of rotation p, q, and r are such that the total quantity passing through the galvanometer is nought. The resistance and coefficient of self-induction of the galvanometer are g and λ, and the electromotive force and resistance of the battery E and b. Then if x, y, z be the imaginary currents on the meshes,*

$$r(x-y)+p(x+z)+gz+\lambda\frac{dx}{dt}=0$$

$$b(y+z)+r(y-x)+sy+L\frac{dy}{dt}=E$$

$$b(y+z)+px\qquad+qz\qquad=E.$$

Eliminating y and z, we have

$$Ax+B\frac{dx}{dt}+P\frac{d^2x}{dt^2}+C\quad=0\quad\ldots\ldots\quad(2)$$

where $$A=\begin{vmatrix} r+p+g & -r & p \\ -r & s+b+r & b \\ p & b & p+q+b \end{vmatrix}$$

$$B=\lambda\begin{vmatrix} s+b+r & b \\ b & p+q+b \end{vmatrix}+L\begin{vmatrix} p+g+r & p \\ p & p+q+b \end{vmatrix}$$

$$P=(p+q+b)L\lambda,$$

$$C=E(ps-qr).$$

* For the method of solving such problems by the employment of these imaginary currents, see a most interesting paper by Dr. Fleming, in the *Proceedings* of the Physical Society, Vol. VII., p. 215.

Integrating (2) we obtain

$$A\int x\,dt+B\int dx+P\int\frac{d^2x}{dt^2}dt+\int C\,dt=0\quad\ldots\ldots\quad(3)$$

The effect on the galvanometer needle may be divided into two parts—one, the first rush of electricity that occurs through it when the battery circuit is closed during the time the galvanometer is not short-circuited, and the diminution of this current through zero and its increase in the opposite direction until it reaches a certain definite value, when the currents in the arms of the bridge have become steady; the second, the dying away of this reverse current in the galvanometer while it is short-circuited. These two effects we shall consider separately.

To ascertain the amount of the first effect, we must integrate between t equals nought and t equals T, since, by hypothesis, T is the interval that elapses between the closing of the battery circuit and the short-circuiting of the galvanometer.

Integrating between these limits we have

$$\int_0^T x\,dt=Q_1,$$

where Q_1 is the quantity of electricity that flows through the galvanometer in the time T,

$$\int_0^T dx=-\frac{C}{A},$$

since this is the final steady value of the current x, which is nought at time nought.

Also $$\int\frac{d^2x}{dt^2}dt=\frac{dx}{dt}$$

and $$\frac{dx}{dt}=0 \text{ at time T},$$

since, by hypothesis, T is long enough for the currents to become steady. To find the value of $\frac{dx}{dt}$ at time nought, we have the fundamental differential equation for the current through the galvanometer

$$gx+\lambda\frac{dx}{dt}=V,$$

where V is the potential difference at the terminals of the galvanometer at any time. And since where t equals nought x equals nought, we have at time nought

$$\frac{dx}{dt}=\frac{V_0}{\lambda},$$

where V_0 is the value of the potential differential at the terminals of the galvanometer at time nought

and $$V_0=-\frac{Ep}{p+q+b},$$

since at time nought both x and y are nought, therefore at time nought

$$\frac{dx}{dt}=-\frac{Ep}{\lambda(p+q+b)},$$

and therefore $$\int_0^T\frac{d^2x}{dt^2}dt=-\frac{Ep}{\lambda(p+q+b)}.$$

Lastly $$\int_0^T dt=T,$$

therefore equation (3) reduces to

$$AQ_1-B\frac{C}{A}+P\frac{Ep}{\lambda(p+q+b)}+CT=0.$$

Next, let us consider the dying away of the current in the galvanometer after it is short cuited. We may now use simply the equation

$$gx+\lambda\frac{dx}{dt}=0,$$

if the resistance of the short circuit be very small compared with that of the galvanometer itself.

Multiplying by dt, and integrating from t equal T to t equal T', say the time the short circuit is removed, we have

$$gQ_2+\lambda\int dx=0,$$

where Q_2 is the quantity of electricity that passes through the galvanometer while short-circuited. At the moment after short-circuiting

$$x=-\frac{C}{A},$$

the steady value of the current, since the self-induction of the galvanometer prevents any instantaneous change in the current passing through it, and when t equals T' the current in the galvanometer is nought, since, by hypothesis, the time of short-circuiting T' - T is long enough for the current in the galvanometer to die away,

$$\therefore\int_T^{T'}dx=-\left(-\frac{C}{A}\right).$$

Now, in order that there may be no deflection of the galvanometer, we must have

$$Q_1+Q_2=0,$$

$$\therefore\frac{BC}{A^2}-\frac{P}{A}\frac{Ep}{\lambda(p+q+b)}-\frac{C}{A}T=\frac{\lambda}{g}\cdot\frac{C}{A}\quad\ldots\ldots\quad(3)$$

Digitized by Google

Let σ be the apparent steady increase of the resistance of the coil with self-induction (of which the ordinary resistance is s) produced by the rotation of the commutator at speed corresponding with the times T and T^1, then

$$p(s+\sigma)=rq,$$
$$\therefore C=-Ep\sigma.$$

Substituting this value for C, and for P its value $L\lambda(p+q+b)$ in equation (3), we have

$$L=\sigma\left(T+\frac{\lambda}{g}-\frac{B}{A}\right). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Now $\frac{\lambda}{g}$ and $\frac{B}{A}$ are usually small compared with T, therefore when this is the case

$$L=\sigma T,$$

the simple formula previously referred to.

Referring to Fig. 1, it will be seen if the brushes B_2 and b_2 touch over a small area, and if the centres of these areas are in a plane passing through the axis of rotation, that T is simply equal to

$$\frac{\text{angle between the slits in the two commutators}}{360\times\text{number of revolutions per second.}}$$

We may call

$$\frac{\text{angle between the slits in the two commutators}}{360\text{ deg.}}$$

the lead or l, and l will be equal to $\frac{1}{4}$, for example, when each of the cycle of operations given in the table last for one quarter of a revolution.

Introducing l we have, if σ be in ohms,

$$L=\frac{l}{n}\sigma \text{ second-ohms},$$

where n is the number of revolutions of the commutator per second, or

$$L=\frac{60\,l\sigma}{N}\text{ second-ohms} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where N is the number of revolutions per minute.

A large number of experiments were made in May 1886, with a solenoid of which the resistance was about 4 ohms at ordinary temperatures, to see how nearly the coefficient of self-induction determined by using the double commutator arrangement running at different speeds, and with different leads, agreed with the coefficient of self-induction determined by Lord Rayleigh's method, which gave 0 0215 second-ohm for the solenoid alone, and 0 517 second-ohm when a certain iron core was introduced into the solenoid.

The following are some of the results obtained with the solenoid without the iron core when the lead

$l=\frac{1}{12}$ about :—

N	$s+\sigma$	σ	$L=\frac{60\,l}{N}\sigma$
0	4·06		
660	6·70	2 64	0·0200
760	7·00	2·94	
860	7·50	3·44	0 0200
997	8·00	3·94	
1117	8·50	4 44	
1240	9·00	4·94	
1362	9·50	5·44	0·0200
1450	11·00	6·94	
1850	12·00	7·94	0·0204
2335	13·50	9·44	0 0202

Plotting these results on squared paper, we obtain the curve A A A (Fig. 3), the abscissæ representing the values of N, the number of revolutions per minute, and the ordinates the values of $s+\sigma$, the apparent resistances of the solenoid at the various speeds. This curve we see is a perfectly straight line, which means that the increase of resistance is proportional to the speed ; or, in other words, the approximate formula (5) for calculating L may be employed with *any* of the results, and the value of L so obtained from a few of the results is given in the last column of the preceding table. That we may use the approximate formula at all for L shows us that the term

$$\frac{\lambda}{g}-\frac{B}{A}$$

in the expression (4) is negligible in comparison with T ; and that we may use it even for the result obtained with the highest speed of rotation employed, viz., 2,335 revolutions per minute, shows us that $\frac{1}{12\times2335}$ minute, or about 0 0022 of a second, which is the time the galvanometer remains unshort-circuited after the battery circuit is closed, is long enough for the currents in the bridge to reach their steady value.

The values of the coefficient of self-induction obtained, 0 020, are approximately equal to 0·0215 second-ohm, the value obtained by Lord Rayleigh's method, and that they are not exactly the same arises from the difficulty, already referred to, of estimating the lead l accurately with the eye. This would not introduce any inaccuracy in the actual use of the instruments, since for a given adjustment of the relative positions of the commutators A B and C D in Fig. 1, the value of l is a constant, and this value would be determined once for all, not by the eye, but by an actual experiment made with a coil of known self-induction. We were not, however, calibrating the instrument on the assumption that the approximate formula (5) was true, but using the instrument to see how nearly (5) might be employed. In our experiment l was probably not $\frac{1}{12}$ exactly, but more nearly $\frac{1}{11}$.

Experiments were now made with the lead l, equal about to 0·3.

$l=0·3$ about

N	$s+\sigma$	σ	$L=\frac{60\,l}{N}\sigma$
0	4·06		
770	5·00	0·94	
1120	5·50	1·44	
1600	6·00	1·94	Mean value, 0·0218 ohm-second.
2000	6 50	2 44	
2410	7·00	2 94	
2860	7·50	3·44	

These results when plotted give the straight line B B B. Instead, therefore, of calculating the value of L from several of the results, as before, we may more accurately determine it from the point at the end of this line corresponding with a speed of 3,000 revolutions per minute, and an apparent resistance of 7·7 ohms, that is an apparent increase of 3·64 ohms. This gives for L the value 0·0218 second-ohm, also not differing much from the true value 0·0215 second-ohm, considering that the exact value of the lead was not known.

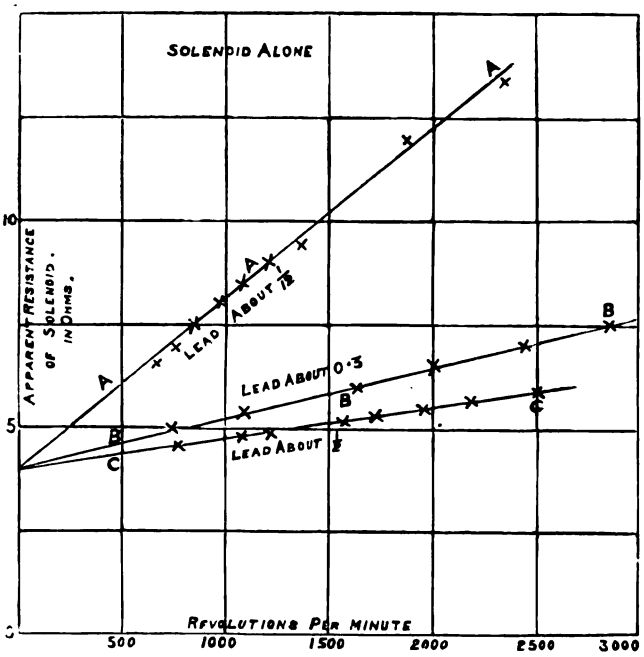

FIG. 3.

Lastly, experiments were made with a lead of about $\frac{1}{2}$, with the following results :—

$l=\frac{1}{2}$ about

N	$s+\sigma$	σ	$L=\frac{60\,l\,\sigma}{N}$
0	4 1		
820	4·7	0 6	0·0219
1100	4 9	0·8	
1240	5·0	1·0	0·0217
1560	5·2	1·1	
1700	5·3	1·2	0·0212
1950	5 5	1·4	
2220	5·7	1·6	0 0216
2500	5·9	1 8	0 0216

Here again the points all lie very nearly in the straight line C C C, and the values given in the last column, calculated from some of the points, are all nearly equal to one another and to the true coefficient of self-induction of the solenoid.

It is clear, therefore, that with speeds up to 3,000 revolutions per minute and higher, and with leads varying from $\frac{1}{12}$ to $\frac{1}{2}$, any single experiment correctly made gives the true value of the self-induction by the use of the simple formula

$$L=\frac{60\,l}{N}\sigma.$$

We see from the formula, and from the experiments which substantiate it, that the smaller the lead and the higher the speed of rotation of the

Digitized by Google

commutating arrangement, the larger is the value of apparent increase of resistance—that is, the more sensitive is the test.

The iron core was now inserted in the solenoid, and a series of experiments made with leads equal to $\frac{1}{12}$, $\frac{1}{8}$, $\frac{1}{4}\frac{3}{6}$, $\frac{1}{3}\frac{7}{6}$, in the respective sets of experiments. The results are shown by the curves D D D, E E E, F F F, G G G. It will be observed that, although the speed of rotation of the commutating arrangement did not exceed 680 revolutions per minute, the observations do not lie even approximately in a straight line, until the lead $\frac{1}{4}\frac{3}{6}$ is employed, and even when the last lead $\frac{1}{3}\frac{7}{6}$ is used there is still curvature in the line. This great difference between the curvature of the lines for a range of even slow speeds when the iron core is introduced, and the perfect straightness of the lines beyond the highest speed, 2 800 revolutions per minute, employed with the solenoid alone, arises from the coefficient of self-induction of the solenoid, with the iron core inserted, being about twenty-five times as great as the self-induction of the solenoid alone. Hence the smallest interval, T, between the closing of the battery circuit and the short-circuiting of the galvanometer that can be employed is much larger when the iron core is inserted than when the solenoid alone is used. Consequently the lead must be large or the speed must be slow for the results to lie in a straight line. The curve D D D, obtained with the lead of about $\frac{1}{12}$, is too far from straight for any portion of it to be used in calculating the coefficient of self induction, with the simple formula—in other words, so small a lead was unsuitable to be used. The greater part of the next curve, E E E, is also too far from straight to be used, but the first observation, corresponding with a speed of 156

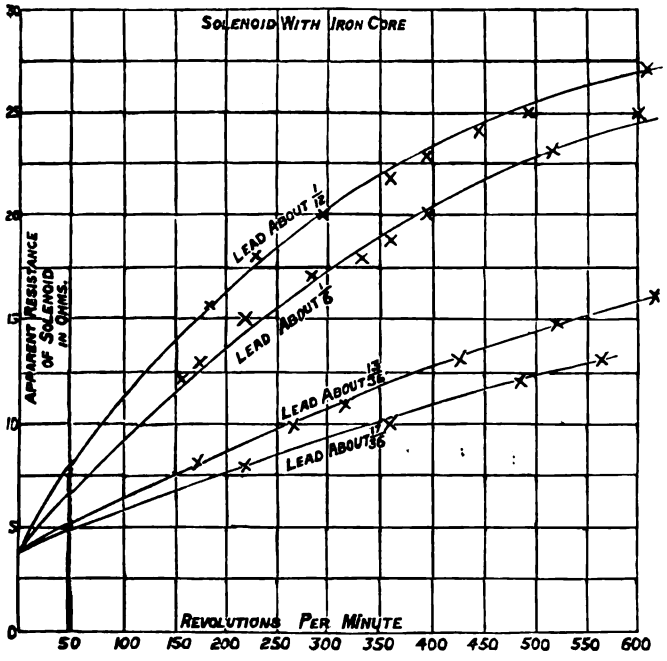

FIG. 4.

revolutions per minute and an apparently increasing resistance of 8 ohms, is on a portion of the curve sufficiently straight to give an answer not much smaller than the truth. The result so obtained is

$$L = \frac{60 \times \frac{1}{6}}{156} \times 8$$

$$= 0{\cdot}513 \text{ second-ohm},$$

which is not very much less than the true value of the coefficient of self-induction of the solenoid with the iron core, as determined by Lord Rayleigh's method, which, as before mentioned, gave 0·517 second-ohm.

With the lead of about $\frac{1}{8}$, the lowest speed at which an observation was taken was 170, corresponding with an apparent increase of resistance of 4 ohms. This gives

$$L = \frac{60 \times 13}{170 \times 36} \times 4$$

$$= 0{\cdot}510.$$

If we take the next speed, 260, corresponding with an increase of resistance of 6 ohms, we find L equal to 0·500.

The last curve G G G, obtained with the largest of the leads, about $\frac{1}{3}\frac{7}{6}$, is the one that, being straightest, will probably give the best results, but as even this is not quite straight we must expect to obtain slightly too low a value. The two first observations correspond with speeds of 220 and 355 revolutions per minute, producing an apparent increase of resistance of 4 and 6 ohms. The values of L obtained from these results are 0·515 and 0·482 second-ohm, from which we should conclude that the true answer was a little higher than 0 515 second-ohm, and this we know is correct, as the true answer is 0·517 second-ohm.

That it is necessary to employ only slow speeds when a large coefficient of self-induction is being measured is no disadvantage, because when the self-induction is large the apparent increase of resistance at even slow speeds is great, and so can be accurately measured.

(To be continued.)

SOCIETY OF TELEGRAPH-ENGINEERS—STUDENTS' MEETING.

The first students' meeting was held in the Society's Library on Thursday, the 5th inst., Prof. W. E. Ayrton, F.R.S., in the chair. Prof. Ayrton briefly addressed the meeting, stating the objects of such meetings, and expressing his warm sympathy with the movement. Mr. J. Rance then opened the discussion upon Dr. Thompson's "Telephonic Investigations," and was followed by Messrs. A. H. Bate, A. C. F. Webb, Wordingham, E. Thomas, and Cooper. Prof. Ayrton replied to several questions, and closed the discussion.

A vote of thanks to Prof. Ayrton terminated a very successful meeting.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The twenty-seventh ordinary general meeting of shareholders in this Company was held at Winchester House, 50, Old Broad-street, on the 11th inst. under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting, and the minutes of the last general meeting, which were approved by the present meeting and signed by the Chairman.

The CHAIRMAN having stated that that was the twenty-seventh occasion within the last fourteen years upon which his present duty had devolved upon him, continued: It is rather difficult to avoid monotony in discharging this duty on so many successive occasions. However, gentlemen, the monotony has not been altogether of a disagreeable character. I think there have been in the reports and addresses which I have had the honour to make to you elements which have rendered the monotony satisfactory or at least palatable to you. I remember that in the early days of our enterprise our proceedings were somewhat diversified by a not unnatural expression of impatience that our undertaking had not at once realised all the anticipations formed of it. However, that is now a matter of history, for of recent years our proceedings have been tolerably amicable between the Directors and the shareholders, and I think the state of the room on the present occasion proves that the shareholders have no want of confidence in the management of the Directors. Those of you who have taken the trouble to read the present report—which is a condensed history of the transactions of the Company for the last six months—will see that the satisfactory elements to which I have alluded as existing in former reports are not wanting on the present occasion. I am happy to say that we are able to report that all your plant is in excellent condition. We have had during the last six months a complete immunity from any casualty, and our traffic has shown a substantial increase both on the previous half-year and on the corresponding period of the previous year. I may incidentally mention that that satisfactory increase of traffic is still going on, and that up to the present time we are receiving considerably more than we obtained last year. We have been able to pay our usual dividend and to carry a very substantial sum to the reserve fund, and also to carry forward a considerable sum to the current half-year's accounts. Well, under those circumstances I do not think the resolution that I have to propose requires any very great eloquence or argument on my part to enforce it There are one or two incidental circumstances to which I would venture just to allude. We have been threatened with competition in several directions. These threats have not as yet assumed what I may call a tangible form. All I can say about them is that we are exercising the greatest vigilance as to those threatened attacks, and your Board will take such steps in the event of their becoming tangible as they may consider necessary to support the interests of the Company. You are aware that for a long period past we have been engaged in negotiations for strengthening—as I stated on a former occasion—our position in Brazil. Those negotiations have as yet led to no practical result; but we are not without hope that they may do so, and in the meantime we must ask the continued forbearance of the shareholders, for it will be obvious to you that to disclose our hand, and show what our operations are in the midst of a negotiation, would not be a wise or a useful course for us to pursue. I do not think there is any other circumstance that I need allude to, and I beg leave to propose that the report of the Directors and the accounts to the 31st December, 1886, now submitted, be approved and adopted.

Sir JAMES ANDERSON: I beg leave to second that.

The CHAIRMAN, in answer to a question, said that what he had referred to as competition was that there were several proposals to construct new lines which would practically compete with the Company. However, as he had already stated, they had not yet assumed any very decided form. The resolution was then carried unanimously.

On the motion of Mr. GRIFFITH, seconded by Mr. NICOL, a cordial vote of thanks was passed to the Chairman and the Directors.

The CHAIRMAN, in acknowledging the vote, stated that the Directors would continue to do their best, as in the past, to promote the interests of the Company.

The proceedings then terminated.

Submarine Cables Trust.

The sixteenth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices of the Trust, Winchester House, No. 50, Old Broad-street, on Wednesday, the 11th inst., Mr. John Pender presiding.

The SECRETARY (Mr. Lewis Wells) read the notice convening the

Digitized by Google

meeting, and the minutes of the previous meeting, which were confirmed and signed by the Chairman as correctly entered. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: On referring to the accounts, it will be seen that our revenue for the past financial year amounted to £14,528, against £21,826 in the previous year. As stated in the report, this is mainly owing to the falling off in the dividend paid by the Anglo-American Company, from whom we received only 5s. per cent., against £1. 5s. in 1886; but we have also had diminished returns from our other investments—the Eastern Company has only paid 5½ per cent, against 6 per cent., and the Eastern Extension Company 6 per cent., against 7 per cent. It will be observed that we brought into the past year's accounts £1,949, and carry forward a balance of only £95. We have, in fact, divided our revenue up to the hilt, not even retaining in hand sufficient to meet the expenses of the current half year. Knowing that the interest on the coupons was cumulative, the trustees wished to give the certificate holders as much as possible on account of the April coupon, as they did not see their way to pay the balance of 30s. before October 15th. The expenses of the Trust are £1,359, against £1,349, or only £10 more than last year, in spite of the extra cost of stationery and clerical labour in having to stamp the coupons in the office here—a work which was not necessary when the coupons were paid in full by the bankers. For the current year we estimate that we shall receive at least 1 per cent. from the Anglo-American Company, against 5s. last year, while it is hoped that the Eastern Extension Company will again be in a position to pay a dividend of 7 per cent. In this case, although we shall not be able to pay our coupons in full, we shall give the certificate holders a fair return on their investment. There can be no doubt, gentlemen, that the American cable war of rates must terminate some time; as to when it will terminate I am not prepared to say, but having a strong belief that there is a period when it is positively throwing away money to continue such a war, I hope the termination is perhaps nearer than at present we should be disposed to expect. The reduction of returns, and therefore of dividend, on the part of the Eastern and Eastern Extension Companies arose through very material reductions made in the tariffs at the Berlin Conference. That reduced the income for the moment of these companies by something like £100,000. Of course it takes time to recoup this loss, and temporarily their dividends had to suffer, and consequently we have had to suffer with them. There was a Colonial Conference the other day, in which telegraphs were discussed. The result of that conference is, I think, to leave us in a better and stronger position than we have occupied for a very long time. I am therefore hopeful that before I have the pleasure of seeing you again the traffic will continue to show that vitality which has hitherto been so remarkable in telegraphs, and that we shall be able to go back both in the Eastern and Eastern Extension to our old dividends, and I hope also that the war of rates to which I have referred will be terminated in the interests of the Anglo-American and all concerned. Altogether, I think the prospects are good for those who hold in this Trust, and that we shall before long be in a better financial position than we are in to-day. With these remarks, I beg to move:—"That the report and accounts of the Trustees, now submitted to the meeting, be approved and adopted."

The Right Hon. Viscount MONCK seconded the motion, which was carried unanimously.

The CHAIRMAN: The next resolution is one that rests with the shareholders, and I shall be pleased if any of them will move it.

Dr. HATHAWAY: The resolution which has been put into my hands is: "That Messrs. John G. Griffiths and Mr. John Gane be re-elected auditors of the Trust for the current year, at a remuneration of £25 each," which I beg to move.

Mr. DAVIES seconded the motion, which was agreed to unanimously.

On the motion of Mr. DAVIES, seconded by Dr. HATHAWAY, a vote of thanks to the Chairman and Directors was cordially passed.

The CHAIRMAN: Gentlemen, we are always pleased to have our services recognised by the shareholders on occasions of this kind. We do our very best for your interests, and when that best is appreciated by you it makes us still more earnest to carefully look after your affairs. As I said before, I hope by the time we shall meet you again we shall be able to report a better state of things.

The proceedings then terminated.

West India and Panama Telegraph Company (Limited).

Report of the Directors to be presented to the twentieth ordinary general meeting of members, to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 18th inst., at 12 o'clock:—

The amount to credit of revenue is £37,930. 18s. 11d., and the expenses have been £27,934. 18s. 5d., leaving a balance of £9,996. 0s. 6d. which, with the balance of £2,292. 13s. 0d. brought from last account, makes a total of £12,288. 13s. 6d. with which it is proposed to deal as follows:—

Payment of 6s. per share on account of arrears of dividend on the first preference shares	£10,368 18 0
Balance to current half year's account	1,919 15 6
	£12,288 13 6

The traffic receipts for the six months show an increase of £147. 12s. 3d. as compared with the corresponding period. The expenses on account of repairs of cables have been exceptionally heavy during the half year, amounting to £4,800 in excess of the corresponding half. Both vessels have been more continuously engaged. The Jamaica-Colon section, referred to in the last report, was repaired on the 24th December after prolonged operations, rendered extremely costly and tedious by the great depth of water and the rocky nature of the sea-bed. The cable was eventually recovered from a depth of 1,613 fathoms. After completing this work the ss. "Grappler" resumed operations on the original (duplicate) Jamaica-Porto Rico section, but had to be recalled in order to proceed with other repairs. The Holland Bay-Ponce cable failed on the 30th ult., but was repaired on the 7th inst. The "Grappler" will now be ordered home, and will return to the West Indies with 250 knots of deep sea cable referred to in the last report.

The attention of the Board has been directed to a proposal which has been submitted to the French Chamber of Deputies by the Minister of Posts and Telegraphs, to authorise the guarantee of a gross revenue of £40,000 per annum for the construction of a cable between Para (Brazils) and New York, touching, among other places, at the French Islands of Martinique and Guadeloupe, which have been connected with the telegraphic systems of the world for the past 16 years by means of this Company's cable. The Directors have addressed communications to the French Government, pointing out the inevitably disastrous financial results of such an undertaking, and the inadequacy of the advantages expected, to justify so large a liability. A final decision has not yet been arrived at.

Of the £50,000 Six per Cent. Debentures which fell due on the 31st December last, £37,900 have been extended for a further term of five years at 5 per cent. per annum. The balance of £12,100 is still for disposal. In accordance with the Articles of Association, Sir James Anderson and William Andrews, Esq., retire at this meeting and offer themselves for re-election. John George Griffiths, Esq., the auditor, also retires and offers himself for re-election.

CITY NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY. — The traffic receipts of this company for the week ended 6th inst. amounted to £4,001.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company for April amounted to £20,320. From January 1 to April 30 they were £81,520, and for the corresponding months in 1886 and 1885 £78,480 and £89,200 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 6th inst. were £3,322.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 30th April are £3,156, as compared with £2,467 in the corresponding period of 1886.

NOTICE OF REMOVAL.—The Direct Spanish Telegraph Company inform us that the general offices of this Company have been removed to Winchester House, 50, Old Broad-street, E.C.

NOTES.

INTERRUPTION OF A FRENCH CABLE.—The cable between Porto-Rico and the Antilles is interrupted.

FIUME.—The port and town of Fiume are to be lit by electricity; power will be obtained from the River Fiumera, at a point some miles from the town.

TUNNEL LIGHTING.—The Hoosac Tunnel, near Boston, U.S., is to be lit throughout by Westinghouse transformers. The tunnel is 5½ miles in length.

CENTRAL LIGHTING STATIONS IN AMERICA.—The number of central electric lighting stations in full operation at the present time in America is given as 426.

WATERFORD.—Messrs. Laing, Wharton and Down have obtained the contract for lighting the streets of this town with arc lamps. The Thomson-Houston system will be employed.

CONTRACT OPEN.—Tenders are being asked for the lighting of the town of Port Louis in the Mauritius; no particular method is stipulated for. Further information may be obtained from the town clerk.

MADRID.—The *Imparcial* states that efforts are being made to arrange for the lighting by electricity of the grounds of the forthcoming Philippine Exhibition at Madrid. An installation of at least 6,000 lights is spoken of.

SHIP LIGHTING.—The North of Scotland and Orkney and Shetland Steam Navigation Company's new steamer, "St. Sunniva," has been fitted with an installation of 136 lamps by Messrs. J. D. F. Andrews and Co., of Glasgow.

"ELECTRO-DEPOSITION."—We have received from Messrs. Crosby Lockwood and Co. a copy of the second and revised edition of the work by Mr. Alexander Watt on "Electro-Deposition: A Practical Treatise on the Electrolysis of Metals, with several chapters on Electro-Metallurgy."

ORDERS FROM INDIA.—The Gülcher Company have, we hear, received orders for three installations for lighting palaces in India. The present order consists of one 100-light installation, and two 500-light installations, with engines, boilers, dynamos, accumulators, and fittings complete.

"THE SPECIALIST SERIES."—We have received from Messrs. Whittaker and Co. a copy of the second edition of the "Specialist Series" volume on "Magneto and Dynamo Electric Machines." This edition contains a preface and an additional chapter on the latest types of machine, by Mr. W. B. Esson.

"THE STORAGE OF ELECTRICAL ENERGY."—We have received from Messrs. Whittaker and Co. a copy of Mr. Bedford Elwell's translation of the collected edition of Gustave Planté's papers, entitled "The Storage of Electrical Energy, and Researches in the Effects created by Currents combining Quantity with High Tension."

"ELEMENTARY PRACTICAL PHYSICS, VOL. II.: ELECTRICITY AND MAGNETISM."—We have received from Messrs. Macmillan and Co. a copy of the second volume of the Owens College series of "Elementary Practical Physics," being the volume on "Electricity and Magnetism," by Prof. Balfour Stewart, F.R.S., and Mr W. W. Haldane Gee, B.Sc.

OPENING OF THE PARIS-HAVRE TELEPHONE LINE.—On Sunday week the telephone line between Paris and Havre was opened for the public service. The distance is about 110 miles. At present communication can only be obtained between the Bourse at Paris and the Central Exchange at Havre. The tariff has been fixed at the rate of 1fr. for five minutes' conversation.

MEXICO.—We learn from the City of Mexico that Commissioners of the State of Zacatecas are travelling in America studying the telephone, telegraph, and electric lighting systems of the large cities there. After inspecting the American cities, the commissioners will sail for Europe for the same purpose. They are generally authorised to examine all inventions and improvements in electrical apparatus.

SLATE CUT-OUT FRAMES AND SWITCH BLOCKS. — Mr. Rashleigh Phipps sends us a sample of his cut-out blocks and covers, made entirely in slate. The advantage, and in many cases the necessity, of using non-inflammable material for the support of fusible cut-outs has long been recognised, and we have seen no material that fulfils the purpose better than slate. These cut-outs are manufactured in all sizes to suit wood casing.

HAMBURG.—The municipality of Hamburg has appointed a committee to consider a proposal for undertaking electric lighting by means of transformers, and in connection with the gasworks it already owns. The capital outlay involved in the scheme under consideration amounts to £50,000. If it is decided to carry out the work the contract will, it is understood, be placed in the hands of Messrs. Schwartzkopf, of Berlin.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—The next meeting of this society will be held at 25, Great George-street, S.W., on Thursday, May 26th, at 8 p.m, when a paper on "Underground Telegraphs" will be read by Charles J. Fleetwood, member, followed by the paper on "Driving a Dynamo with a very Short Belt," by Profs. W. E. Ayrton, F.R.S., and John Perry, F.R.S., which was adjourned from the last meeting.

THE ELECTRIC LIGHT IN THE HOUSES OF PARLIAMENT.—In the House of Commons, in reply to Dr. Tanner, Mr. Plunket (First Commissioner of Works) said that he was deterred by the large expenditure from proposing the adoption of anything like a general system of electric lighting for the House and its offices, but he had directed the preparation of a complete scheme and estimate should the House be disposed to sanction the large expense.

LIGHTING OF THE LYCEUM THEATRE AT EDINBURGH.—The Lyceum Theatre at Edinburgh has been supplied with 200 Victoria lamps of 10 and 17 candle-power, for which current is generated by Victoria dynamos and a Raworth engine. The plant has been erected under the superintendence of Mr. Geipel, district manager of the Anglo-American Brush Corporation. Outside the theatre an arc lamp of 4,000 candle-power is hung, and is run on the same circuit as the incandescents.

PADUA.—The town of Padua supports a telephone exchange which numbers 232 subscribers, and at the low rate of £6 per annum managed last year to pay a 6 per cent. dividend, and carry forward a substantial sum. All the wires are of silicium bronze. The communications in 1886 numbered on the average 738 daily. It appears, however, that the Telephone Company of Milan claim to possess the sole right to the use of the Bell-Blake instruments, and have served a notice to that effect upon the Padua Company.

NARROW ESCAPE OF EDISON.—An American journal says:—"The safe arrival of Mr. T. A. Edison, Mr. E. T. Gilliland, and the other members of their party in this city on May 1st was the occasion of their receiving numerous congratulations over their very narrow escape from drowning on Thursday, 28th April. The entire party of eight persons were standing on a pier at Kissimmee Springs, two miles from Barlow, in Florida, when the pier collapsed and precipitated all the party except

Digitized by Google

Mr. Edison and Mrs. Gilliland into the water, which was eight or ten feet deep." Fortunately no lives were lost.

CITY AND GUILDS OF LONDON FINSBURY TECHNICAL COLLEGE "OLD STUDENTS'" ASSOCIATION.—At the last meeting of the Finsbury Technical College "Old Students'" Association, Mr. John Rance, from the Central Institution, read a paper on "Electric Railways." The relative advantages and disadvantages of battery and conductor systems were pointed out, and the efficiency of reversible batteries discussed. The paper concluded with a short description of the various lines now in operation and in process of construction, and tables were given showing the relative cost of electric and horse traction. Altogether the subject was very thoroughly treated, and induced an animated discussion.—At the same meeting Mr. Howard Swan read a short and appropriate paper on "Taking Lecture Notes."

THE TELEGRAPH SERVICE.—In the House of Commons on Tuesday last the Chancellor of the Exchequer, in reply to Sir W. Harcourt, said that the net revenue of the Post Office for the year 1881 was £2,586,436, and the estimated net revenue for the year 1887 was £2,400,000, showing a decrease of £186,000. In 1881 the net revenue from the telegraphs was £413,000. In 1886-7 there would be a deficiency of £223,000, so that in six years there was a falling off in net revenue of £536,000. This was without taking into account the interest on the purchase money of the telegraphs, which was £326,000. If that was added there would be a deficit on the telegraph service for 1886-7 of £549,000. The falling off was due not to diminished receipts, but to the additional expenditure, especially that incident to the parcels post and the introduction of sixpenny telegrams.

ARC LAMPS AT THE NEWCASTLE EXHIBITION.—At the opening of the Newcastle Exhibition on the 11th inst. it was noticed that the arc lamps in the gardens were very unsteady. We understand that this was due to the contractors being late with their work, so that there was no opportunity of regulating the lamps prior to the opening night; in fact, many of the lamps were only hung the same day. As the lamps have been properly regulated they have become perfectly steady, and those in the engine room and north gardens are now burning well, and there is every reason to believe that the installation will be perfectly satisfactory as soon as the contractors have had time to adjust every lamp for its work. Had the installation been completed a week before the opening of the Exhibition the flickering noticed would no doubt have been avoided, and it is certainly unfortunate that this was not done.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—The following is the programme of the session of the American Institute of Electrical Engineers, which is being held during the present week:—Papers will be presented on "Storage Batteries," by Mr. E. P. Roberts; "Results with Hard Drawn Copper Wire," by W. Maver, jun.; "Novel Phenomena in Secondary Generator Systems," by Prof. Elihu Thomson; "Installation of Electric Lighting Plants," by Mr. J. A. Powers; "Electric Lighting in Trains," by Mr. J. Wetzler and Mr. T. C. Martin; "Note on the Differing Temperature Coefficients of the Different Coils of a Fine Rheostat," and "Note on the Change from Negative to Positive of the Temperature Coefficients of some Carbon Filaments," both by Prof. W. A. Anthony; and "The Best Ratio of the Section of the Core of the Gramme Armature to the Section of the Field-Magnets," by Mr. D. C. Jackson, of Cornell University.

TEMPORARY INSTALLATION AT BRIDGWATER.—The *Bristol Times and Mirror* of May 16 says: "Upon the occasion of the visit of the Somerset Agricultural Association to Bridgwater last week, very material aid was rendered to the decorations, which were carried out on a large scale, by the use of the electric light. Messrs. King, Mendham and Co., of Bristol, were able at one day's notice to brilliantly light up a portion of the show by means of arc lamps, the dynamo being driven by a portable engine in a yard at some distance from where the lamps were suspended. As was to be expected, the light proved a great attraction to the country visitors, and many came in to the show having seen the glare of the light from a distance of two or more miles. The light was in every way a success, and the manner in which the work was carried out reflects great credit upon the firm, considering the extremely short notice they received at which to undertake it."

THE CALCULATION OF WORK DONE BY AN ALTERNATING E.M.F.—In another column will be found an interesting communication relating to the work done by an alternating E.M.F. in a compound circuit, the numerical data being taken from Messrs. Sharp and Kent's system of regulating series-wound transformers by means of "induction-rings," which we describ d in a recent issue. The calculation affords a good illustration of the immense difference between alternating and continuous E.M.F.'s as regards the energy expended. It is shown, for instance, that in a particular case, while both total current and E.M.F. in the secondary circuit remain constant, the consumption of energy may be caused to vary between 1,000 watts and 6·24 watts. This affords an excellent illustration (and one which should be very beneficial to those electricians who have not yet taken the trouble to make themselves acquainted with the laws of alternating currents) of the necessity for getting rid of the idea that the product E C represents watts when talking of alternating currents. The writer proceeds to show that in the same circuit, if the E.M.F. were continuous instead of alternating, instead of 6·24 watts, work would be done at the rate of 21·5 horse-power.

THE SCHOOL OF ELECTRICAL ENGINEERING AND SUBMARINE TELEGRAPHY.—The managers of this school, Messrs. W. Lant Carpenter and L. Drugman, inform us that they have just received from Mr. H. R. Kempe, of the engineer-in-chief's office, General Post Office, who undertakes the duties of external examiner in electrical engineering, a very satisfactory report on the results of the Easter examination for the vellum certificate of the school. This certificate is granted only to those pupils who get seventy per cent. of the marks, both in the theoretical and in the practical questions, and who have also passed the examination in the course of lectures on mechanical engineering. Certificates were awarded to twelve out of eighteen pupils who presented themselves from the class of the senior instructor, Mr. H. D. Wilkinson. The following is a list of their names and mark percentages:—B. S. Giles, 96·66; H. O. Holford, 96·66; T. D. Clapham, 93·33; W. J. Walters, 90·66; W. A. Purdom, 90; S. H. Lury, 89·33; E. G. Tidd, 88; G. Gregg, 88; F. W. M. Chapman, 87·33; P. J. Pringle, 85·33; A. W. Kingham, 76·66; J. R. Cotton, 74. All these gentlemen passed in electric lighting and transmission of power; three of them, Messrs. Gregg, Purdom, and Tidd, passed also in telegraphy and telephony.

ATTENDING CHURCH BY TELEPHONE.—We learn from a local paper that at the National Telephone Company's offices, Sheffield, last Sunday morning and evening a number of ladies and gentlemen listened to the service held at St. Paul's, Manningham, near Bradford, to which church the telephone wires had been extended. The voluntaries were exceedingly good. The anthem in the morning, "Where withal shall a young man?" by Sir G. J. Elvey, and in the evening the "Motet,"

Digitized by Google

"Oh God, when Thou appearest," by Mozart, were most distinctly heard, and the Sheffield audience more than once expressed their high appreciation of the skill of the organist (Mr. J. H. Rooks) and the singing of the choir. The tenor's voice was exceptionally fine. The preacher both morning and evening was the Rev. F. Hill, M.A., Rector of St. Luke's, Miles Platting. At the conclusion of the morning and evening services, Mr. Swithinbank, the company's manager at Huddersfield, and Mr. Young, inspector there, played at their residences several sacred tunes on the piano and harmonium respectively, which were distinctly heard by the audience at Sheffield. Conversation was also carried on in ordinary tones with Manchester, Preston, Burnley, Leeds, Huddersfield, and other towns, and in each case the articulation was as clear as if talking over a local line. Telephone communication between Sheffield, Manchester, Leeds, and other large centres, although not taken so much advantage of in Sheffield as in other towns, will in the near future prove invaluable to the commercial community. Mr. Northam, the Sheffield district manager, was warmly thanked by his congregation for the privileges granted them on Sunday.

COUNTRY HOUSE LIGHTING.—The Gülcher Electric Light and Power Company have completed the lighting of Mr. Neville's country house at Elsted, near Petersfield. The installation, which has been working satisfactorily for some time, has been carried out in the following manner:—The plant consists of a 2 horse-power Spiel petroleum engine, made by Messrs. Shirlaw and Co., of Birminghnm, and drives on to a No. 1 Gülcher shunt-wound dynamo machine. The dynamo charges a battery consisting of 27 Elwell-Parker 15 plate cells. A Mountain improved switch-board is placed by the dynamo machine, and is used for charging and discharging, running the dynamo and accumulators together in case of emergency, or running the lamps direct from the dynamo. A 5-contact switch is also provided on the same slate slab for adding extra cells as the E.M.F. falls, and the volt and ammeters with measuring plugs are arranged so that by inserting or withdrawing a plug the E.M.F. can be measured. The current from the dynamo room is led to the house by a pair of 7-15 cables, made by Messrs. Callender and Co. In the hall special hammered iron brackets have been used, in order to lend themselves to the character of the surroundings. In the bed rooms special raising and falling pendants, designed by Mr. Mountain, are used. Throughout the house the shades are of cut glass. The Gülcher Company adds:—"This installation is, we believe, one of the first where a Spiel petroleum engine has been used for private house lighting, and the result, as far as experience has shown, leads to the conclusion that they are admirably adapted for this purpose, and should be very largely used in the future."

CONVERSAZIONE.—The first *conversazione* of the Royal Society for the season took place last Wednesday evening at Burlington House, when Prof. Stokes (the president) received a numerous and brilliant assembly. The display of scientific apparatus on this occasion was specially interesting. Among physical appliances one which attracted much attention was shown by Prof. Rücker, F.R.S., explaining, by reflection on a screen, the use of Newton's famous rings in testing the expansion of metals by heat. By this beautiful contrivance, which Fizeau has employed, effects can be rendered visible which must be almost infinitesimal in amount. In the adjoining section Mr. C. V. Boys explained a mechanism for shooting threads of glass, emerald, and other substances melted in an oxyhydrogen flame, and attached to an arrow projected from a cross-bow. By this means he drew out filaments of incredible tenuity, quartz for example, so fine that the thinnest parts are beyond the power of any microscope to define. Dr. Marat, F.R.S., had at work in the reading room an instrument for speedy volumetric measurement of carbonic acid, where also Prof. Unwin, F.R.S., exhibited instruments for measuring extensions and compressions in materials subjected to stress to the nicety of the one hundredth thousandth part of an inch. In the principal library Mr. Norman Lockyer displayed a number of interesting photographs of the solar spectra; the Earl of Rosse, sketches of Jupiter and Mars; Prof. Ewing, earthquake records produced by the seismograph; Prof. the Rev. C. Pritchard, F.R.S., star-photographs; and Profs. Ayrton and Perry, the "Secohmmeter." In the department of biology, Mr. Edgar Crookshank, Dr. Klein, and Prof. Marshall Ward showed under the microscope a large number of those micro-organisms which produce disease in men, animals, and plants.

THE ELECTRIC LIGHT IN CHELSEA.—At the meeting of the vestry, on Tuesday, Mr. Mossop, the chairman of the Electric Light Committee, in moving the recommendation of the committee that the offer of the Cadogan Electric Light Company, in which they agree, in the event of the Vestry granting permission for overhead wires, to be bound by all the clauses both of the order and the Act confirming the same, as if the company were the actual holders of the said order and confirming Act, be accepted. This was seconded.—Mr. Kingsbury said he did not think the Vestry could comply with this, when they had for a long time been trying to put down overhead wires.—Mr. Wright said that the Vestry had objected to the Chelsea Electric Supply Company putting up overhead wires, and he did think the Vestry should object to this company putting up overhead wires. It was an impossibility to say that the wires would not break with the snow. He moved that the Vestry do not consent to the overhead wires.—Mr. H. Young said by the decision of the law courts the parochial authorities had not much to do with this question. The Cadogan Company were the same company, he believed, as the Grosvenor Company. The houses built by Messrs. Trollope were fitted with wires, and those gentlemen were connected with this company.—Mr. Mossop said the Cadogan Company wished to place themselves in the same position as the company that had an order, and in that order there was a clause which prevented overhead wires. He thought it was folly for two people to go to one district and compete when there were other parts of Chelsea that were open; but that was nothing to do with the Vestry.—The chairman, in answer to Mr. Wright, said he believed this company asked to be allowed to put themselves under the same terms as if they had been through the form of getting a provisional order.—The amendment was put and lost, and the motion carried.—The committee recommended, with regard to the letter received from the Chelsea Electricity Supply Company, that the Vestry should inform the company that this Vestry will assent to the Board of Trade using its powers under Section 70 of the Provisional Order to suspend the obligations of the company in all streets in Schedule A, save in the following:—Pont-street, Hans-place, Lennox-gardens, Lennox-gardens Mews, Clabon Mews, Cadogan-square, Cadogan-street, Draycott-street, and Draycott-place, for such term of years as they see fit.—Mr. Mossop moved the adoption of the report. This was to allow the company to reduce its area.—Mr. Moon seconded the motion, which was agreed to.

LAUNCH OF AN ELECTRIC YACHT.—The electric yacht, "The Countess," which has been built by Messrs. Lester and Perkins, at the Royal Albert Docks, to the order of the Electric Locomotive and Power Company, was launched on Saturday afternoon last. The boat has been constructed from the designs of Mr. Lester, and is 90ft. in length, 11ft. 6in. in the

Digitized by Google

beam, and 5ft. 6in. deep, and will draw about 3ft. of water. The motive power will be supplied by Elieson storage cells, and the screw will be driven by an Elieson motor of the pattern which has already been employed with some success for tramcar traction. The ceremony of christening was performed by the Countess of Galloway as the vessel hung suspended from one of the dock company's huge and powerful derricks. The boat was then swung bodily over the basin, and lowered into the water. The company afterwards adjourned to the workshop, where a light repast had been provided. Mr. T. Wickham proposed "The health of the Countess of Galloway," and spoke of the honour which her ladyship had done them by coming amongst them that day to perform the ceremony of christening the new boat. He felt that that was a ceremony full of promise and fraught with great advantage, not only to themselves, but to the community at large. The vessel they had seen launched that day would combine in itself two very important inventions which their company thought would some day make a very great sensation in the world. In that vessel there would be their new electric motor applying electricity in a new form, and their own accumulator or storage battery, to which they attached very great importance indeed. Therefore in thanking her ladyship for the act she had performed that afternoon, they felt that she had launched and put before the world a scheme which was fraught with great consequences in the future. They felt and hoped that the day was not far distant when not one of Her Majesty's ships or the vessels of the great navigation companies would go to sea without a launch of that kind. In returning thanks on behalf of the Countess, the Earl of Galloway said that had her ladyship not been confident of the success of the scheme they had in hand, he was certain she could not have been persuaded to assist in its development. He also took great interest in the proceedings of the Electric Locomotive and Power Company, but he did not think that vessel would have been built had it not been for the suggestion of Mr. Lester, who was one of the most active of their directors, and who by means of his firm had been instrumental in its construction. Other toasts followed.

Proposed Electric Lighting in Cork.—A special meeting of the Standing Committee of the Cork Corporation was held on Monday week to consider the representations and estimates of Mr. D. O. Bate, of the firm of Messrs. Laing, Wharton and Down, electrical engineers, London, respecting the Thomson-Houston system of electric lighting, with a view of ascertaining if the employment of such a system was practicable and less expensive than the present system of lighting the city by gas. Mr. Bate was called before the committee, and said that since the council meeting had referred him to the committee he had called upon Mr. M'Mullen, the city engineer, who had furnished him with particulars, on which he was able to base somewhat of an estimate as to the number of electric lights required to replace a certain number of gas lights. Approximately, 1,300 lamp posts carried a little over 1,300 jets, and the cost of their maintenance was £4,883. As against that, the corporation could probably profitably utilise 100 arc lights in a number of the streets of the town, leaving the small and crooked streets, which could not be lighted successfully by electricity, to be lighted in the present way. Basing his calculation at £24 per arc, the arcs would cost £2,400 per annum. At the lowest estimate each of these lamps would take the place of six gas jets. That would leave 700 gas jets in the small streets, which would cost, at the same rate, £2,629, and that, added to £2,400, made £5,030, as against £4,883 by the present system of lighting. That was an excess of £147. But in some places he could extinguish ten jets for one electric light, and, making allowance for this additional saving, he found the cost of lighting to be £4,654, £229 less than the cost at present. His esitmates were based on the figures for the year 1885. The city was illuminated by gas, at an average of nine hours per night; and he reckoned for keeping the electric lamps alight for ten hours, the same as his firm usually reckoned for English towns. If the corporation would use oil in the smaller streets, like the Waterford people, they would gain £700 a year. The Lighting Committee of Waterford had accepted the tender of his firm to light the streets of that city for the next five years, and this was now awaiting confirmation by the council. After some discussion it was finally resolved "that Mr. Bate and the engineer select within the channels the sites for 100 electric lamps, Mr. Bate then to furnish an estimate for supplying and maintaining such 100 lights for three or five years; the engineer to ascertain exactly what number of the present gas lamps might be extinguished if those 100 electric lights were erected."—*Gas World.*

Galvanometer Deflection by Alternating Currents.—The interesting and important discovery connected with alternating currents, made by Dr. Fleming in this country (and re-discovered apparently a little later by Prof. Elihu Thomson in America) renders it also interesting to note what was previously known with regard to the use of the galvanometer, with alternating currents. In Dr. Fleming's galvanometer (see *The Electrician*, May 6th) it will be remembered that the suspended needle takes the form of a thin copper disc, and the force by which it is deflected is due to the couple established between the alternating field of the coils and the Foucault currents in the disc, the latter being subject to a retardation due to the time constant of the disc, which has the effect of disturbing the equilibrium between the magnetic effect of the reversals. The fact that a *magnetised* needle is, under certain conditions, deflected in an alternating field was, however, observed by Poggendorff at least as early as the year 1838 (*Pogg. Ann.*, Vol. XIV., p. 353). The phenomenon was named by Poggendorff "Doppelsinnige Ablenkung." Thirty years later, at the meeting of the British Association at Norwich, a paper was read by the Hon. J. W. Strutt (Lord Rayleigh) "On a Permanent Deflection of the Galvanometer Needle by a Rapid Series of Equal and Opposite Induced Currents." This paper was not, however, printed in the *Transactions* of the Association, where the title alone appears. The next mention of the subject which we have been able to find occurs in 1876, when Mr. Chrystal contributed to the December number of the *Phil. Mag.* a paper entitled "Bi- and Uni-Lateral Galvanometer Deflection"; where (following Poggendorff) bi-lateral deflection refers to the deflection of a magnetised needle by alternating currents, which, under certain conditions, may be directed indifferently to either side of zero according to the accident of the first impulse, actual zero being in fact a position of unstable equilibrium. Mr. Chrystal made, however, the discovery that a different effect comes into play when the permanent field in which the needle moves is very strong compared with the alternating field, due to the current in the coils. In this case the equilibrium of the needle while at zero is much more nearly stable than in the previous case; if, however, before the current is started, the needle be moved into any position, either to the right or left of zero, then, on starting the current, it remains deflected upon that side of the scale. Mr. Chrystal enters into a mathematical explanation by which both effects are accounted for. It is, however, clear from what we now know that, owing to the Foucault current effect, the complete theory of the deflection of a magnetised needle must be very complex.

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 519, Vol. XVIII.)

ERRATA.—On page 479, Vol. XVIII., the two last lines of the chapter should read as follows:—

The output $\propto \mu \times$ angular velocity $\times$ (linear dimensions) $^{\frac{7}{2}}$

or output $\propto \mu \times$ peripheral velocity $\times$ (linear dimensions) $^{\frac{5}{2}}$

Given the quality of iron we have now the necessary data from which to calculate the value of ρ,

for $$\zeta = Z_2 - Z_1 = \frac{p_1}{\rho};$$

thus $$\rho = \frac{p_1}{Z_2 - Z_1} = \frac{v}{\text{diameter of armature}},$$

v being constant for all sizes of the same type.

After the above value is thoroughly well determined by experiments made with a number of machines, the estimated maximum E.M.F. will afford a means of gauging the comparative magnetic quality of the iron, in which, by bringing this or some equally good test to bear, we may hope in time to get a more strict uniformity.

Returning to our design, we have now to fix upon the cross section of the field-magnets. Knowing the value of Z_2 (making $\sigma_2 = \sigma_1$) we have

$$AB = \frac{Z_2}{18\sigma_2}.$$

In dealing with the length of the cores, we must adopt a similar treatment to that which was employed for the dimensions of the armature, viz., a balance must be struck between the heating effect and the radiating surface.

At first sight this may seem a little difficult, because the conditions are not quite the same as in the armature, where conduction of the heat to other parts of the machine was negligible. A little reflection will, however, show that the ratio between the amounts of heat dissipated respectively from the surface of the magnet bobbin itself and from other surfaces on the frame, &c., is constant for machines of any one type. Thus, having found a coefficient giving good practical results in one case, we may be sure that it will serve for all sizes, having the same general configuration. A point of considerable practical importance arises from the above considerations, and although implicitly contained in the treatment, it will bear emphasis, viz., that the density of current in both armature and magnet winding must necessarily be diminished as the linear dimensions are increased.

For suppose the winding to consist of a single turn of solid copper, the resistance would then be inversely proportional to the linear dimensions, which we will denote by L. Thus $r \propto \frac{1}{L}$. The energy in watts absorbed in this resistance is $w \propto \frac{C^2}{L}$, and by the conditions $\frac{C^2}{L} \propto L^2$ thus $C \propto L^{\frac{3}{2}}$; but if the density were to remain constant C would vary with L^2.

Since in practice magnets have to be wound with wires of various sections in which the coefficient of insulation assumes different values, care must be taken to allow sufficient space for the smallest sizes which are likely to be used. Of course the proposition that the core surface may be used as the basis of calculation for the number of watts converted into heat in any one bobbin only holds good if the ratio between the core radius and the radius to the outside of the winding is kept constant for all sizes. This ratio, we have seen, is subject to modifications in a given size when wound for different purposes, but a constant *average* ratio may very well be maintained. It is now necessary to fix both this average ratio and also a ratio between the heat dissipated and the core surface. For the first, a good proportion will be to make the average depth of winding one-half the core radius, or, if rectangular in section, one-fourth the short diameter. For the second, a maximum of one watt per square inch of core surface will be found a fairly safe rule in general practice. We now have P the exciting power, A B the core section (from which we can also obtain the depth of winding), and a certain ratio in any given case between the length of core and the work done thereon—that is, a given number of watts per linear inch. This gives the sectional area of the wire for series winding, for then the current C flowing in each bobbin is known, and writing d for the depth of winding, w for the watts per linear inch, l for the length of a mean convolution, and A for the copper section, we have

$$\frac{d\,l\,\mu^2}{162 \times 10^4 \,.\, A^2} = \text{resistance} = \frac{w}{C^2},$$

from which A is found. The number of windings n per unit length follow immediately from this equation, and $\frac{P}{2Cn}$ then gives the length of core, the numeric being inserted because there are in general two cores to each magnet.

The length of the iron portions of the magnetic circuit are now known and have been determined in such a way as to secure for them a minimum value; the length of the air gap, δ, has, however, so far only been fixed in a purely arbitrary manner, and we must try to deal with this quantity a little more fully.

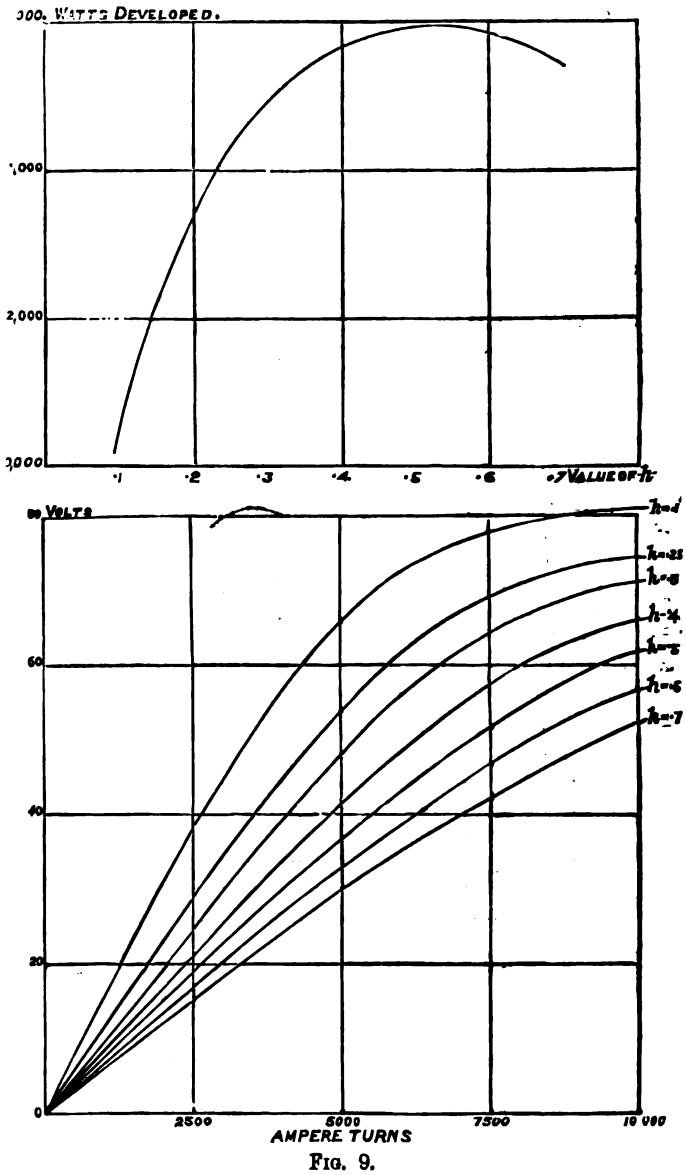

FIG. 9.

It consists of two parts, viz., the depth of winding, which we will call h, and the clearance Q necessary to mechanical safety. What we have now to do is to express the output as a function of h, in order that the effect of modifications in this latter quantity may be traced. As our object is to secure the

Digitized by Google

highest efficiency as well as the greatest output, we will cause the two quantities to vary in the same direction by keeping the work done in the armature constant. We then have from equation (2).

$$r_a = \frac{t(a+2\beta)}{\beta(b-\beta)},$$

where

$$t = \frac{N^2}{162 \times 10^4 . \pi \mu^2 P^2 R},$$

$$a = q + p \text{ and } b = 1 - p;$$

thus

$$r_a = \frac{t\left(a + \frac{2h}{R}\right)}{\frac{h}{R}\left(b - \frac{h}{R}\right)}.$$

Also $C = \sqrt{\frac{W}{r_a}}$ where W = watts in armature. We then have

$$C = \left\{\frac{\frac{Wh}{R}\left(b - \frac{h}{R}\right)}{t\left(a + \frac{2h}{R}\right)}\right\}^{\frac{1}{2}}$$

The electromotive force E can also, as we have seen, be expressed in terms of Z, the number of lines passing through the armature core. In this expression Z is a function of h, but as there is also a saturation term, k, which is affected by modifications in h, a general solution of the problem presents serious difficulties. We can, however, take a particular case, and calculate from the tangent formula already given a number of curves of E.M.F. corresponding respectively to certain values of h; a vertical line can then be struck at any suitable exciting value along the line O X, and the points of intersection with the curves will give the E.M.F. in each case. These values will then be taken to form products with the corresponding values of C, and thus another curve of the products of E C may be made in which the various values of h are taken along the line O X. Although such a curve is limited in its actual application to one particular machine, it may yet be taken as *characteristic* of all machines. A case is therefore worked out in Fig. 9 in which the constants are as follows :—

W = 600.
R = 7·625.
t = ·000336.
a = ·8.
b = ·6.
N (number of turns on armature) = 320.
n (revolutions per minute) = 900.
R_A = 1·22.
R_F = 2·85.
ρ (resistance of air leak) = 80.

SIR WILLIAM THOMSON'S NEW ELECTRIC MEASURING INSTRUMENTS.

Standard Electric Balances.

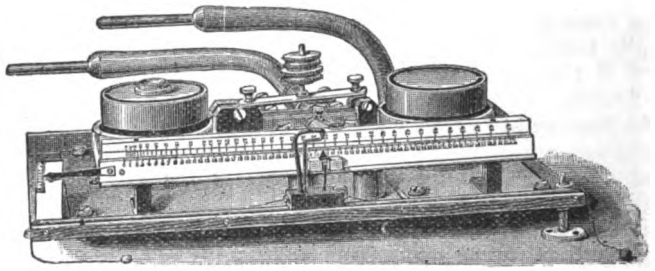
1. These instruments are founded on the mutual forces, discovered by Ampère, between movable and fixed portions of an electric circuit. The shape chosen for the mutually-influencing portions is circular, and each such part will be called for brevity an ampere ring, or sometimes simply a ring, whether it consists of only one turn or of any number of turns of the conductor.

2. In the balance instruments each movable ring is actuated by two fixed rings—all three approximately horizontal. In each of the balance instruments there are two such groups of three rings—two movable rings attached to the two ends of a horizontal balance arm pulled, one of them up and the other down, by a pair of fixed rings in its neighbourhood. The current is in opposite directions through the two movable rings to practically annul disturbance due to horizontal components of terrestrial or local magnetic forces. In the direct reading voltmeter there is only one fixed ring acting on a single movable ring, which is attached to one end of the balance arm and counterpoised by a weight at the other end.

3. In all the instruments the balance arm is supported by two trunnions, each hung by an elastic ligament of fine wire, through which the current passes into and out of the circuit of the movable rings or ring.

4. In the balance instruments the mid-range position of each movable ring is in the horizontal plane midway or nearly midway between the two fixed rings which act on it. The current goes in opposite directions through the two fixed rings, so that the movable ring is attracted by one of the fixed rings and repelled by the other.

5. In the balances to measure direct currents of from 5 amperes to 1,000 amperes the outer diameter of each pair of fixed rings is somewhat smaller than the inner diameter of the movable ring, and the proportions are so arranged that the force experienced by the movable ring is very nearly constant through half a centimetre on each side of its middle position This is the sighted position for the ordinary use of the balance; and it is marked by the zero line or middle one of five stout black lines across the scale traversed by the pointer of the balance.



Standard Electric Balance.

6. In the balance instruments to measure alternate currents of all strengths, and direct currents of from 5 milliamperes to 10 amperes the fixed rings are larger than in the instruments to measure the larger direct currents. Their outer diameters are greater and their inner diameters less than that of the movable ring which moves between them, above one and below the other. The position of the movable ring equidistant from the two fixed ones is a position of minimum force, and the sighted position, for the sake of stability, is above it at one end of the beam and below it at the other, in each case being nearer to the repelling than to the attracting ring by such an amount as to give about $\frac{2}{10}$ per cent. more than the minimum force.

7. In the balance instruments to measure alternating currents (which may be also used for direct currents) of from 5 amperes to 1,000 amperes the main current through each circle, whether of one turn or of more than one turn, is carried by a wire rope of which each component wire is insulated by silk covering, or otherwise from its neighbour, in order to prevent the inductive action from altering the distribution of the current across the transverse section of the conductor.

8. The balancing is performed by aid of a weight which slides on an approximately horizontal graduated arm attached to the balance; and there is a trough fixed on the right hand end of the balance, into which the proper counterpoise weight is placed, according to the particular one of the sliding weights in use at any time (§ 11 below). For the fine adjustment of the zero a small metal flag is provided (as in an ordinary chemical balance) actuated by a fork, with a handle below the case outside as shown in the drawing. To set the zero, the left hand weight is placed with its pointer at the zero of the scale, and the metal flag is turned to one side on the other until it is found that, with no current going through the rings, the balance rests in its sighted position.

Digitized by Google

9. To measure a current the left hand weight is slipped along the scale until the balance rests in its sighted position. The strength of the current is then read off approximately on the fixed white scale (called the inspectional scale) with aid of the finely divided scale, for more minute accuracy, according to the explanations given in § 13 below. Each number on the inspectional scale is twice the square root of the corresponding number on the scale of equal divisions.

10. The slipping of the weight into its proper position is performed by means of a self-releasing pendant hanging from a hook carried by a sliding platform, pulled in the two directions by two silk threads passing through holes to the outside of the enclosure.

11. Three pairs of weights (sliding and counterpoise) in the ratios of 1 : 4 : 16 or 1 : 4 : 25 are supplied with each instrument, adjusted so that each pair gives a round number of amperes, or half amperes or quarter amperes, or of decimal sub-divisions or multiples of these magnitudes of current, on the inspectional scale.

12. The useful range of each instrument is about from 1 to 25 of the smallest current for which its sensibility suffices. The ranges of the different types of this instrument regularly made are—

I.	Centi-ampere balance :	from 2 to 50	centi-amperes.
II.	Deci-ampere	„ „ 1 to 25	deci-amperes.
III.	Ampere	„ „ 1 to 25	amperes.
IV.	Deca-ampere	„ „ 4 to 100	„
V.	Hecto-ampere	„ „ 20 to 500	„

The following table shows for each type of instrument the value per division of the inspectional scale corresponding to each of the three pairs of weights :—

	I. Centi-amperes per division.	II. Centi-amperes per division.	III. Deci-amperes per division.	IV. Amperes per division.	V. Ampere per division.
1st Pair of Weights.	·25	1	1	·5	2·5
2nd „	·50	2	2	1·	5·0
3rd „	1·0	5	5	2·	10·0

13. The fixed inspectional scale shows approximately enough for many purposes the strength of the current; the notches in the top of the aluminium scale show the precise position of the weight corresponding to each of the numbered divisions on the white scale, and practically annul error of parallax due to the position of the eye. When the pointer is not exactly below one of the notches corresponding to integral divisions of the inspectional scale, the proportion of the space on each side, to the space between two divisions, may be estimated with considerable accuracy. Thus we may readily read off 34·2 or 34·7 by estimation with little chance of being wrong by one in the decimal place. But when the utmost accuracy is required the reading on the fine scale of equal divisions must be taken, and the strength of current estimated by aid of the table of doubled square roots appended to these instructions. Thus, for example, if the reading is 292 we find 34·18, or say 34·2 as the true scale reading for strength of current; or, again, if the balancing position of the pointer be 301 on the fine scale we find 34·65 as the true reading of the inspectioual scale.

14. The centi-ampere balance, with a thermometer to test the temperature of its ampere rings, and with platinoid resistances up to 2,000 ohms, serves to measure potentials of from 10 volts to 200 volts.

Direct-Reading Vertical-Scale Voltmeter.

15. This instrument is commonly called "engine-room voltmeter," because it can be read at such a distance as across an engine room, and requires for taking a reading no balancing manipulation as in the balance ampere meters. It is convenient not only for engine rooms, but for use in any part of an electric light installation, or in houses supplied with electric light. It shows, by inspection, whether the potential is exactly the proper amount, or, if not exactly so, by what fraction of a per cent., or by what percentage, down to 10 per cent. below or up to 10 per cent. above, it differs from the proper amount.

16. The inspectional voltmeters consist of—

a. A fixed platinoid resistance, in circuit with a fixed and a movable ampere ring.

b. A V-trough rigidly fixed to the movable ring, and carrying the weight proper to the potential to be measured and the temperature of the instrument.

c. A thermometer to show the temperature of the ampere rings.

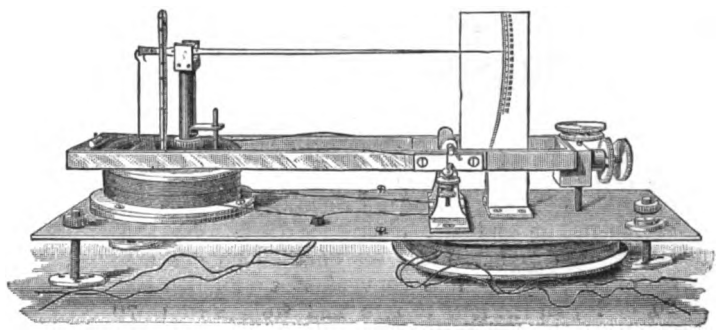
d. A lever, multiplying the motion of the movable ring, and showing the potential to be measured on a vertical graduated scale.

17. The fixed and movable ampere rings are each composed of many turns of fine insulated copper wire, with a total resistance of about 100 ohms. The amount of the added platinoid resistance depends on the potential to be measured in the ordinary use of the instrument. Thus, for example, for potentials of from 10 per cent. below to 10 per cent. above 100 volts, the platinoid resistance is 700 ohms; for potentials of from 10 per cent. below to 10 per cent. above 200 volts, the platinoid resistance is 1,500 ohms.

18. Temperature error is practically annulled in the use of the instrument by simply reading the thermometer (14 *b* and *c*), and seeing that the weight in the trough is the one corresponding to the temperature. Five weights, corresponding to temperatures centigrade of 15°, 20°, 25°, 30°, 35°, are supplied with the instrument in receptacles marked with the temperature, so that no mistake can be made in seeing that it is the right weight that is in use on the instrument at any time.

Marine Voltmeter.

19. The mass of the moving part of the balance voltmeter and engine room voltmeter is too great to be convenient for sea use, and instead a small oblate of soft iron supported on a stretched platinoid wire in the centre of a solenoid of fine copper wire, connected in series with platinoid resistances, variable according to the potential to be measured, serves for marine voltmeter. A pointer carried by the oblate shows, by inspection, direct reading of currents of from 90 to 120 milliamperes. When, as is most commonly the case, the mean potential to be measured is 100 volts, the platinoid resistance is adjusted to make up, along with the fine copper wire solenoid (of which the resistance is about 60 ohms), a total resistance of 1,000 ohms. Thus, the direct reading of potential on scale is in volts.



Engine Room Voltmeter.

20. This instrument is founded on the principle that an oblate spheroid of soft iron, movable round a diameter, tends to turn its equatorial plane parallel to the lines of force in a uniform magnetic field. In the zero position the equatorial plane of the oblate is inclined about 45° to the lines of force of the solenoid, and torsion by the upper and lower parts of the bearing platinoid wire tends to turn it into a position perpendicular to the lines of force. This tendency is balanced by a stop against the needle when no current, or any current not exceeding 90 milliamperes, passes through the solenoid. When a current exceeding 90 milliamperes passes, the torsion couple is balanced by the couple due to the electro-magnetic force.

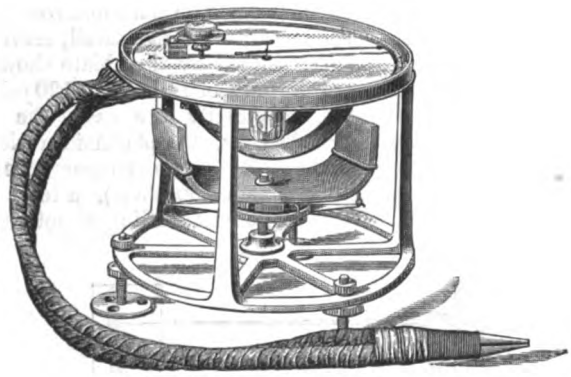
Adjustable Magneto-Static Current Meter.

21. This instrument has an advantage over the balance instruments, important for some practical purposes, of being available as an accurate direct-reading current meter through a continuous range of from 1 to 90 or 100. Its disadvantages are that it is not available as an alternate current instrument,

Digitized by Google

and that the magnetism of the steel directing-magnet does not remain absolutely constant. With good quality of steel, a proper preliminary *ageing* of the magnet (by heating it several times in boiling water and cooling it again, and subjecting it to somewhat varied rough usage) brings it to a condition in which its magnetism may probably remain exceedingly nearly constant month after month and year after year. Still, it can never be relied upon as absolutely constant. It is therefore necessary to have some means of accurately retesting and readjusting the instrument at any time. This is always easily done with the utmost accuracy if one of the balance ampere meters is available as a standard.

22. When the instrument is used as a lamp counter, primary adjustment or readjustment, at any time, can be performed with great ease, without the aid of any other measuring instrument, by turning the screw platform which bears the adjusting magnet, so as to raise it or lower it until it is found that the deviation from zero produced by the current of any number of lights shows a corresponding number on the scale of the instrument. After each motion of the magnet the zero of course must be readjusted, which can be done either by throwing off all the lamps, or throwing the instrument out of circuit, and then turning the magnet till the needle points to zero. The lower screw must be screwed firmly up to pinch the upper screw when the adjustment is completed. If this is done firmly enough the magnet may at any time, without scruple, be turned round on its platform and brought back again whether for setting the zero, or for any other purpose, as it is only by turning the upper screw that the distance of the magnet from the needle can be altered.



Magneto-Static Current Meter.

23. The scale has 100 divisions, corresponding to equal differences of tangents of the angle between the magnetic axis of the needle and the electro-magnetic axis-vertical of the rings. The divisions may be numbered from 0 to 100; but for many purposes it is convenient to number them from 30, 20, or 10, on the left, to zero, and from zero to 70, 80, or 90 on the right; because we thus have larger divisions in the neighbourhood of the zero than when it is taken at the extreme left of the scale, and because it is sometimes convenient to measure small currents in the direction opposite to that of the currents ordinarily measured. For most purposes probably the numbering 10 left to zero and zero to 90 right will be found most convenient. With scales so numbered any number of lamps from 1 to 90 can be counted by integral numbers of scale divisions. Of course this is not possible to any great accuracy, because the lamps are not all rigorously equal, but the lamp counter serves the important practical purpose of showing at any time the exact number of lamps in use when less than 10 or 15, and nearly enough for practical purposes the exact number however many there are. In private houses it is very useful as a check against some lamp or lamps being left accidentally alight in a cellar or safe-room or other place where the fact of its being alight might escape observation for days or weeks together.

24. To count larger numbers of lamps up to 1,000 or more the instrument is made with smaller rings of more massive conductor. The same proportionate accuracy is attained as with the 100-lamp counter.

Adjustable Resistances or Mho-ohm Drum.

25. This is a combination of platinoid* conductors fulfilling the double object of an ordinary box of resistance coils in series, and a mho box by which a set of conductors can be connected any two or more of them in parallel, so that their conductances† shall be added, instead of the resistances being added, as in the ordinary box of resistance coils.

26. The conductors are coiled anti-inductively,‡ on a drum of thick sheet copper to serve the purpose, not only of bearing them and forming the main support of the instrument, but also of conducting away with great freedom the heat that is generated in each coil through which the current is flowing at any time, and so equalising the temperature of the different coils. A copper sheath is fixed outside in metallic connection with copper partition rings which separate the different coils. This sheath serves the purpose of protecting the coils against damage, and of spreading out the heat generated in each coil over a wide surface freely exposed to the external air, and so greatly diminishing the rise of temperature due to currents through the coils. It is also convenient for the application of a water jacket for laboratory or other purposes in which special care as to the temperature of the coils is needed.

27. All the resistances on the drum are connected in series by permanent solderings. The varying connections for the use of the instrument are made by circular copper cams, mounted on vertical copper shafts, connected by solderings and flexible strands with the soldered joints between the coils in series on the drum. Each shaft is mounted so as to work in two positions, an upper and a lower.

28. For making the mho connections all the shafts are placed in the upper position, and the connections are made by turning the cams so as to press on the outer or inner of two concentric copper rings between which the shafts and cams are mounted.

29. For the ohm connections the shafts are let down to their lower position, and the connections are made by turning the cams so as to short-circuit whichever of the coils are not to be included in the sum of the resistances in series. The working of this part of the plan is precisely the same as in the ordinary resistance-box, except that the short-circuitings are made with easier manipulation by cams with single contacts, instead of by removable plugs with contacts on each side of each plug. This halving of the number of the non-soldered contacts is a serious advantage.

30. In order that the single set of resistances may be available both for the connection in series (for ohms) and for the connection in parallels (for mhos) their proportions must be according to powers of 2 as in ordinary weighing by subdivi-

* When the special purpose is the measurement of the conductivity of copper, the conductors of the mho-ohm drum are made of copper instead of platinoid.

Adding E to any combination of the other conductances adds $\frac{1}{2} \times \frac{1}{2048}$ of a Mho to the sum.

sion of the pound into halves, quarters, eighths, sixteenths (or ounces), and half and quarter ounces. Thus when the smallest single resistance on the drum is 1 ohm the other resistances are 2, 4, 8, 16, 32, 64, 128, 256, 512, 1,024, 2,048, and 4,096 ohms, this last being the highest single resistance on the drum as ordinarily made, but higher resistances may be added if desired.

31. The dual system, besides its availability for the two modes of connection, has this advantage, that with it a similar number of coils suffice than in any of the decimal systems of resistance coils ordinarily in use.

BELGIAN ELECTRIC LIGHTING REGULATIONS.

The following regulations for the construction of electric lighting circuits have been issued by the Belgian Postal and Telegraphic Administration :—

1. The lighting circuits shall be entirely metallic, without any earth connections whatever, and connections with water or gas pipes are strictly prohibited.

2. In the case of all portions situated upon State property, or in the neighbourhood of telegraphic or telephonic wires belonging to the State, the conducting wires, if not laid underground, shall be covered with materials which will ensure complete electric insulation, and the whole system must be made impermeable to water.

3. The cables shall be made of sufficient strength to resist any strains to which they may be exposed, and, if necessary, they shall be supported throughout their entire length by wires or metallic cables of the requisite strength, and they shall be placed at a sufficient height to allow the free passage under them of the highest vehicles, and especially of the fire escapes and ladders used for repairing the telegraph and telephone wires.

4. At their points of support on buildings, posts, buttresses, &c., the cables shall be attached in one uniform manner to porcelain insulators, and in such a way that the insulating covering may not be exposed to either mechanical or electrical deteriorations.

5. If bare wires be used for the continuation of cables carried over the places mentioned in Section 1, the bare wire shall not approach within a distance of two metres from any roof or building; it shall be furnished at the points of junction with double insulating covering for a distance of 60 centimeters at least from the supporting insulator, and the junction of the wire to the cable shall be perfectly soldered and insulated.

6. In any places where the direct and return conductors may be near together, or where a dangerous difference of potential may exist, especially in the neighbourhood of the central lighting station, the conductors shall be covered with an additional layer of insulating material; they shall be placed at a distance of not less than two metres from any roof or building, and their distance asunder shall be such as to preclude the possibility of any person touching both of them at the same time.

7. Wherever the lightning conductors cross telegraph or telephone wires, they shall pass underneath the latter at right angles, and at a minimum distance from them of 2 metres. The points of support of these cables shall be at a minimum distance of three metres on one side and the other of the telegraph and telephone wires. To prevent the wires, in the case of breakage, from coming in contact with the electric light conductors, the contractor shall place above each of the latter, along the whole length of the crossing, a metallic wire of sufficient strength

8. The electric lighting conductors and the telephone and telegraph wires shall, as far as possible, not be allowed to run parallel to one another. When this condition cannot be fulfilled the distance between them shall never be less than 12 metres.

9. In conformity with royal decree of the 15th of October, 1876, the contractor shall give to the telegraphic department the preliminary notice prescribed in Section 1 of this decree in the case of any work to be carried out in the neighbourhood of telegraph or telephone lines established or conceded by the Government.

10. The contractor must give a general undertaking to avail himself in his installations of every possible measure recognised by science or by experience as a safeguard.

The installation shall be maintained in the most perfect condition possible, and they shall be tested regularly at least once daily.

11. The contractor shall assume the entire responsibility for all damage or accident arising from his electric light installations.

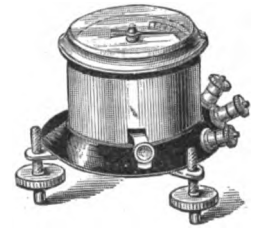
12. The present authorisation is merely permissive; it does not include the right of placing supports upon any buildings or lands belonging to the State, for which a separate authorisation must be obtained in each special case, and it may be revoked at six weeks' notice.

The State reserves to itself the right of making any changes in these regulations, of making new ones, and of demanding at any time that electric lighting conductors, situate on State property, or in the neighbourhood of telegraph or telephone lines established or conceded by the Government, be forthwith removed, without giving any indemnity to the contractor.

13. The installations carried out on State property, and in the neighbourhood of the aforesaid telegraph and telephone wires, may not be modified in the future without special permission from the Government.

NEW PORTABLE HORIZONTAL GALVANOMETER.

This galvanometer, which is illustrated below, has been designed more especially with a view for testing purposes. Its double bobbin is wound with two resistances as in an ordinary detector, and the needle which



swings inside the coils is fitted to a spindle carrying at its upper extremity an agate centre which rests lightly on a delicate needle point, a balanced aluminium pointer being fixed to the spindle just below the cap. By this arrangement a highly sensitive instrument is constituted, and one that is well adapted for testing line circuits, lightning conductor earths, &c. To prevent breakage of the needle point in transit a small lever is so fitted that upon being screwed down the spindle is lifted off its resting place. The scale is carefully engraved on a silvered dial protected by a thick plate glass cover. In using it is only necessary so to place the instrument in the magnetic meridian that the zero is towards the north, and to level it by means of the three levelling screws below the base. This galvanometer has been introduced and is manufactured by Messrs. King, Mendham and Co., of the Western Electrical Works, Bristol.

THE CANADIAN PACIFIC CABLE ROUTE.

The day when wars and rumours of wars will be things of the past has not come yet, nor is that happy time likely to be known by the present generation. Many of our actions, individual and public, are dictated by the fear of what may be, and are not the result of calm reasoning. The proposed Pacific cable is one of those suggestions, and an attempt is being made to frighten the public into the support of a scheme which has few intrinsic merits to justify its claims to attention or support.

The proposed cable is either a business scheme or purely a political scheme. If the latter, the public must consider the matter as taxpayers; if the former, they must consider it as investors. The promoters seem to have an idea that it is partly a commercial and partly a political question, and that from the latter point of view the Government is to pay a subsidy as a guarantee to the investors against loss. It is singular that no ideas of this character were mooted before the building of the Canadian Pacific Railway. The letter of Mr. Finch Hatton, given in another column, considerably clears the ground, and almost for the first time gives the real reasons why a Pacific cable is being promoted. The development of Canada is a praiseworthy object, against which we have not the faintest objection. The moral, however, of Mr. Finch Hatton's letter is that "Civilisation is a failure" and the "Caucasian is played out." The end of all things is to be war. Our industries are to be developed, not as peaceful industries, but as subsidiary aids in the event of war. No doubt in England we are wrong in imagining that if lines of steamers are wanted in the Pacific, lines of steamers will be provided by some of the long-headed business men who are always on the look out for means of profitably employing their capital. It might have been thought, also, that the Canadian Pacific Railway was promoted by business men for business purposes, and not from any transcendental idea of immediately directing the commerce of Australasia by a new route. We venture to deny that the transshipment and transport of goods across the American Continent will find favour in the eyes of shippers. If the Canadian Pacific Railway is to pay, it will be from the development of the country through which it runs, and for which it provides transport.

It is not so very long since a greater than Mr. Finch Hatton argued that Canada must ultimately, and that ere long, become an integral part of the United States; and it may be asked whether this consummation of American politics is beyond the range of probabilities? If not, would not England be pickling a rod for her own back by subsidising the proposed scheme? Of course, the answer to this is emphatic, that there is no probability of such an event happening, and this answer would come from the very people who act as if the next war of England must of necessity be with a certain other nation and its allies. They claim infallibility in one direction, and no one must doubt the correctness of the views they express, otherwise it might again be objected that *viâ* Egypt was not the only route to the East, and that England has at least two other routes, and could, in a very short time, if necessary, provide a fourth, *viâ* the West of Africa, at a much less expense than by the Pacific.

We have no objection to a Pacific cable if it can be shown that it would pay as a commercial speculation, but we have a great objection to see the English taxpayers asked to contribute to a scheme which cannot pay of itself, and which is promoted solely in the hope of business from it assisting the Canadian Pacific Railway to become a paying concern. The new business opened up by the proposed cable would hardly pay for a repairing ship, and its traffic would mostly consist of traffic diverted from existing cables. In a few words the result of laying a Pacific cable would be largely and needlessly to increase the total capital invested in such means of communication to the districts under discussion—viz, the Australasian Colonies. Income would be taken from existing lines, and thus investors would lose on the one hand without gaining on the other, for it is not and cannot be contended that sufficient business would arise to give a fair return, say of five per cent., upon the total capital invested.

Before touching upon an argument which the promoters of the Pacific scheme have most unaccountably overlooked, it will be well to consider the value of one or two statements in the fourth paragraph of Mr. Finch Hatton's letter. He says that, "Of all lines that could possibly be laid it would be most free from any likelihood of interruption, either from natural causes or from the action of a hostile Power." Here is still seen the dominant idea that only Russia or France, and never can the United States be "a hostile power;" but the unforeseen is often that which happens, and what about likelihood of interruption if the States should be hostile? With regard to natural interruptions we can be more positive, and say emphatically that the Pacific Ocean is just as favourable or unfavourable as any other ocean. How does Mr. Finch Hatton know that the bottom of the Pacific is the most "favourable one possible for prolonging the life of a cable," and how can he speak of great depth as being a protection? We remember the late Dr. Siemens advocated the deep, deep sea for safety of cables, but those who have had greater experience say that an unlevel bottom anywhere is dangerous, and the uncertainty and the cost of repairs increases greatly with the depth. From a business point of view deeply laid cables are a delusion and a snare, the bottom of the sea being as diversified as the surface of the land; and while we may think that the bottom of the Pacific is generally a level, it is

Digitized by Google

impossible to believe that a cable can be laid the distance proposed without passing over a number of bad places. These natural difficulties, however, are such as cables have daily to encounter, and we desire only to say that the Pacific presents features no better and no worse than are constantly met with; therefore it presents no special feature to cause it to be preferable to any other route.

With regard to tariffs it may be taken for granted that if the Government sees fit to subsidise the proposed line it will deal completely with the whole question.

It has, we think, been overlooked that the arguments put forward by the promoters of the Pacific cable scheme apply to every other cable. Why should the Pacific cable be subsidised as an alternate route, and the Atlantic cables be left to fight their competitors without State aid? Surely the Atlantic cables are as necessary in the chain as the further link. If the Government is practically to be responsible for the dividend of the new scheme, surely the Government, if the cable is so essential, can borrow the money with less difficulty, at a less cost, and carry out the work themselves. The argument as to the importance of the cable system for imperial purposes leads to the inevitable conclusion that if it is so supremely important the Government should, as in the case of the inland telegraph system, take it over and work it apart from all commercial questions. The fallacy of this conclusion is at once seen, inasmuch as such action would necessitate every Government having its own cable system. It might also be asked whether the subsidisation of a Pacific cable would not rather tend to develop trade in America than with England, and, if so, why should the English taxpayer be asked to support an alternative route to his own commercial disadvantage? A number of other pertinent questions might be asked, but surely enough has been said to show that cables ought to extend more as trade develops new demands, rather than to supply routes which have the sole merit of being alternative. Were it possible to form an international tribunal, the whole cable system would be best worked as an international and unpolitical monopoly. Links here and there in the hands of different companies do not form the best means to get the best results, and were the Pacific cable laid, it would only be one link in the chain, and absolutely at the mercy of some other link.

CORRESPONDENCE.

TELEGRAPH TARIFFS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of 13th inst. you publish the final proposals submitted by Mr. John Pender, the chairman of the Eastern Extension Telegraph Company, to the recent Colonial Conference. I trust that the proposal of the Pacific Telegraph Company, which was also submitted to the Colonial Conference, and which I herewith subjoin, may prove equally interesting to your readers. I have no wish to trespass upon your valuable space by criticising Mr. Pender's proposal and the figures which it contains, for nothing that can be urged in favour of or against the existing system of cables to Australasia and the East has any bearing whatever upon the transcendant importance of establishing telegraphic communication *vid* the Pacific.

If the existing lines of the Eastern Telegraph and Eastern Extension Companies were triplicated throughout it would still leave our communications with the East in their present extremely unsatisfactory state, for there are points of weakness in the Eastern system—such as the transit through Egypt—which nothing could ever render secure. They must inevitably be destroyed in time of war, and in such places ten lines of cables, if they existed, would be just as easy to cut as one.

Everything points to the fact that in the event of war England's military route to the East must be *vid* the Canadian Pacific Railway. It is equally certain that the progress of civilisation will shortly open up the Pacific Ocean as one of the main waterways of the world in time of peace. In order to justify her enormous expenditure on the Canadian Pacific Railway, Canada must extend her communications beyond the terminus at Esquimalt by means of ocean steamers to China, Japan, and Australasia. These liners, while employed as traders and mail carriers in time of peace, could be relied on for transport of troops on the outbreak of war. But without telegraphic communication, of course, it would be impossible to open up the Pacific, either as a highway for commerce or as a military route.

By laying a line of cable as is proposed from Canada to Australia, an alternative means of communication with the East would be established possessing advantages such as no other line could possibly offer. Of all lines that could possibly be laid it would be the most free from any likelihood of interruption, either from natural causes or from the action of a hostile Power. The bottom of the Pacific Ocean is the most favourable one possible for prolonging the life of a cable, while the great depth at which the cable would be laid would be equally efficacious in protecting it, both from the injurious effects of submarine insects and currents, and from the attempts of an enemy's cruisers to cut it.

In conclusion, I would call your readers' attention to the fact that the first proposal to reduce the tariff to Australasia to 4s. per word came from the Pacific Telegraph Company. Further than this, while 4s. a word is fixed as a minimum rate by Mr. John Pender, it is the maximum rate of the Pacific Telegraph Company. Should the estimates of increased traffic be in any way realised, the company will be in a position to effect still further very considerable reductions.—Yours, &c.,

HAROLD FINCH HATTON, Secretary.

Pacific Telegraph Company (Limited),
34, Clements-lane, E.C., 16th May, 1887.

Proposition of the Pacific Telegraph Company (Limited) to the Governments of Great Britain, Canada, and the Australasian Colonies.

1. The Pacific Telegraph Company shall lay a line of cable from Vancouver Island to Australia, touching at Hawaii, Fanning Island, Samoa, Fiji, and New Zealand.

2. The Governments of Great Britain, of Canada, and of the Australasian Colonies shall guarantee to the Pacific Telegraph Company Government traffic to the amount of seventy-five thousand pounds (£75,000) per annum, in such proportions as may be mutually agreed upon by the said Governments.

3. The above guarantee shall date from the completion of telegraphic communication between Canada and Australasia by the company, and shall continue in force for twenty-five years from that date, subject to the following conditions:—

4. In the event of telegraphic communication being interrupted thirty-five days shall be allowed to the company for repairs. If at the expiration of thirty-five days telegraphic communication shall continue to be interrupted, then the guarantee shall be suspended from that date until telegraphic communication be re-established.

5. The rate per word payable by the Governments shall be the current rate charged by the company to the general public, but such rate shall never exceed four shillings per word for the transmission of messages from England to Australasia.

THEORY OF SECONDARY CELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to Mr. Sprague, as far as I understand him, he thinks that electro chemists should not write thermochemical equation in the same way as other chemists, and accuses me of mixing things up because I use symbols in the same sense as nearly all modern chemists. The relation of calories and volts is perfectly understood by both Mr. Fitz-Gerald and myself, and we are in perfect accord as to facts on this point, and we only differ in notation.

Mr. Sprague says I set myself against facts; but he does not say what facts. From the extract quoted by him, it would appear that he thinks that I am wrong either in saying that

Digitized by Google

the E.M.F. of cells cannot be measured by the heats of combination, or that the heats of combination are not measures of chemical affinity. But he does not support his assertion.

Mr. Sprague seems to think discrepancies are partly due to the neglect of the heats of solution, &c.; but I at least have been careful not to forget these. He also thinks "the value depends upon the relative values of the volt, ohm, and ampere," and asks, "Will any electrician be good enough to tell us what those units mean? What is their value? and what is the true mechanical equivalent of a 'volt-ampere-ohm-second?'" I am sorry I cannot tell him what a "volt-ampere-ohm-second" is, or what its "dimensions" are, but perhaps that is because I am a chemist.

No one has striven harder than I against the introduction of the "legal" ohm; but Mr. Sprague is wrong in saying it is related to nothing but the erroneously fixed length of a column of mercury, which no one ever made or will make. It is one of the "true units," the decimal multiples of the absolute units for which Mr. Sprague's heart yearns, and that is the reason why it has been brought forward.

Finally, Mr. Sprague goes on to say that "in the present uncertainty of what the various electrical units mean," he reckons one volt = 23,287·7 calories, which, of course, is inaccurate, in spite of the decimal, and says that we should reduce the calories of actions to the equivalent in grammes. I can only repeat that electro-chemists are only a small portion of the community, and that you cannot expect chemists to alter their notation to suit us. In the meantime, H_2O stands for 18 grams of water, and however much we might like to call it 9 grams, we are not at liberty to do so.

Mr. Williams thinks the heats of solution, or of change of physical state, cause the discrepancies between the chemical affinities and the observed heats of combination; but this is not the case. As a striking example the case of salt and snow may be taken. The intense cold is, no doubt, produced by the change in the physical state of the water; but the affinity of salt for water is not nearly enough to account for the phenomenon. If the result were controlled entirely by the chemical affinities, however small, of course the least affinity of salt for water might force the snow to melt; but in other chemical actions the physical states have great influence. For instance, reactions in solutions generally take place so that solid precipitates can be formed.

That such questions as the heats of solutions come in in cells is shown by the higher electromotive force given when strong sulphuric acid is used—that is to say, when the acid has not to be torn away from its water.

As to the last part of Mr. Williams's letter, I think we are very nearly of the same opinion. I do not regard one part of the reaction as being primary and another as a side influence, but look upon them as of equal importance. Mr. Williams and I seem to be practically of the same mind, so the point is perhaps hardly worth discussing. His apt illustration as to lifting the weight seems a very good way of putting such cases.—Yours, &c, JAS. SWINBURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly correct an error in my letter last week. The reference to Dr. Ferguson's "Electricity" was printed as from an edition in 1886. I wrote, or meant to write, "edition 1866," and wished to show, by thus citing a little volume on my shelves, that the conception of an "electrolytic thread" was old as well as new.—Yours, &c.,

37, Burlington-road, W. E. ALDRED WILLIAMS.

THE CONSTRUCTION OF DYNAMOS.

TO THF EDITOR OF THE ELECTRICIAN.

SIR: I have been reading Mr. Fricker's articles with very great interest, and if you would oblige me by replying to the following questions I should be grateful. I have been designing a dynamo for fifteen 50-volt 60-watt lamps, on the base of the articles by Mr. C. Hering, entitled "Practical Deductions from Franklin Institute Tests." I took the diameter of armature from mechanical considerations, and then assumed a certain induction (in volts per foot) of active armature wire, which I took to be one-fourth of the whole length of wire on armature; dividing this by distance moved by armature in one second gave induction at one foot per second, and multiplying this by 100,000,000 gave lines per square foot, which divided by 144 gave lines per square inch of polar surface. The magnets I designed from experiments with small machines by a rule of thumb process. Now, I ask you, Sir, would this give reasonable results, or have I got hold of the stick by the wrong end? I must apologise for troubling you so frequently, but I am only able to get information up to date by your journal and the kindness of your contributors.—Yours, &c.,

G. T. PARDOE.

[Our correspondent has, we fear, adopted a procedure which cannot be relied upon to give him consistent results in general application. The diameter of the armature should be looked upon as the corner stone of the design, and the other quantities must be governed thereby. Mr. Fricker's papers show how this may be done in a perfectly general manner. It is not possible to predict the results of a dynamo from the information given by our correspondent, though we should be glad, if possible, to render him any further assistance in our power in the way of explanation.—ED. *E.*]

THE LIGHTING OF TURIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to a notice in your issue of the 22nd of April of a communication from a correspondent at Milan, which, being incorrect as to the facts, is likely to mislead and thus injure this company. I therefore beg you to give publicity to the following rectification:—A contract entered into between this company and the municipality of Turin for the lighting of a part of that city had been transferred by this company to Messrs. Bellani Fréres. When, however, Mr. Gaulard went to Turin to put the installation into working order, he found that the cable, which had been furnished by Messrs. Siemens and Halske, of Berlin, could not support the current for which the secondary generators were designed, the consequence being that the cable burnt. Mr. Gaulard offered to alter the secondary generators to suit a current the cable could support, but finding that Messrs. Bellani, although acting as agents of this company, had already on their premises transformers of Messrs. Zipernowski, Déri et Blatby (whom we consider infringers of our patents, and with whom we have suits pending in different countries), applied first to the municipality to verify by a scientific committee the complete and perfect working of our apparatus under the conditions for which they were constructed.

This inquiry, however, Messrs. Bellani opposed, and the whole question is therefore now being submitted to the law courts.

You will understand from the foregoing how unfair it is to imply that the alleged attempts to light a portion of the city of Turin with the Gaulard-Gibbs system were unsuccessful through any fault in that system, which is now sufficiently proved in many installations which are working perfectly.—Yours, &c., J. E. PICKERING, Sec.

National Company for the Distribution of Electricity by Secondary Generators, May 17, 1887.

SECONDARY BATTERY QUESTIONS IN BELGIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 2 of last week's issue of *The Electrician*, in connection with the above subject, the following remarks occur:—"The use of oxide of lead is certainly open to the public, since it has been shown that M. Planté had employed this method in the course of his researches long before M. Faure had dreamt of his patent." Will your Brussels correspondent kindly oblige by giving the authority from which he quotes the above remarks? For some time hints have been thrown out from reliable quarters as to the validity of the Faure patents. If, as stated, the only claim is the method of attaching and retaining the red lead, there is still some hope for a perfect secondary battery, a thing that does not exist at present. Very little interest is being taken in the improve-

Digitized by Google

ment of grids by practical mechanics, as it is generally felt that the present monopoly is valid.—Yours, &c.,

INTERESTED.

ELECTRICAL PHENOMENA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think your correspondent "Leakage" will find that the sparks he refers to have nothing to do with the dynamo at all, but are due to high-tension electricity from the belt. I have frequently drawn sparks from my belt half way between engine and dynamo by holding an iron rule near it, and have been informed by a friend that he has frequently observed the same phenomenon with belts of wood working machinery running at high speed in dry weather.—Yours, &c.,

R. H. C. NEVILE.

Wellingore Hall, Grantham, May 15, 1887.

VOLTS AND CALORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to apologise for supposing that our eminent electricans might be right (after correcting their diatomic blunders) in assuming any reasonable relation to subsist between 23,000 calories and one volt, or, as some prefer to have it, 46,000.

I now find the whole contention to be a flagrant mistake, and for pure lovers of science and common sense, it may be instructive to inquire whether this confusion be not a characteristic effect of the high and abstract methods in which our leaders delight to hide themselves from a common gaze or appreciation.

A *calorie* is a definite amount of heat, resulting from a definite amount of combustion; whereas a *volt* has an indissoluble relation to a current, and is nothing apart from time. One *volt* is the unit of power required to perform unit work in unit time, or, in other words, it is that amount of power which is requisite to drive an ampere of current through an ohm of resistance in one second.

And if this must be compared with calories—an attempt which is probably unwise—then it must be with calories per second, and instead of 46,000, we shall find the volt or volt-ampere relation to subsist with less than one-fourth of a calorie.

If this really be the case, is it worth while to continue these interminable discussions and personal recriminations for a purely mistaken object?

Having investigated this problem from original considerations, I am pleased to find the unexpected issue to be in strict accordance with formulæ previously established by Mr. J. T. Sprague and Mr. D. FitzGerald; but it may assist and encourage some students if we repeat the unfashionable process which does not extend beyond the "Rule of Three." I sought to analyse several batteries (on paper) with different potentials and varying resistances in order to find that one *volt-ampere* invariably means a consumption of 19 grains of zinc or other equivalent per hour, and $19 \div 15{\cdot}43 = 1{\cdot}231365$ grammes per hour, which ÷ by $60 \times 60 = {\cdot}000342$ grammes per second.

I then find that this estimate is strictly confirmed by the recent and very elaborate experiments of Lord Rayleigh and others on the direct electrolysis of copper and silver.

The volt comparison proceeds upon the assumption that if we could find out the number of calories due to an equivalent of zinc when combusted, as in a battery, then this number would represent 1 volt. How such an absurdity could have passed current is amazing to think of.

The direct combustion of zinc = Zn + O (40·5) = 42,500 calories (M. Ditte estimates 44,122). The indirect combustion of zinc in a battery consists of Zn + O = 42,500—Cu + O = 21,885 = 20,615 calories, because for every atom of zinc oxide or sulphate formed there is a corresponding atom of Cu oxide or sulphate decomposed.

These numbers are only approximative, and vary with different authorities; but the *rôle* played by the acid is not fully understood. It is indispensable to dissolve the oxide of zinc as formed; it greatly adds to the conductivity, and in all probability contributes somewhat to the E.M.F. or volt-power. Prof. Silvanus Thompson estimates the total as 23,000, or $46{,}000 \div 2$; Mr. FitzGerald estimates 23,000, and Mr. J. T. Sprague has 23,287 calories.

Now, if we accept this basis, the result easily follows:—

(1) If 32·5 grams : 23,000 calories : ·000342 grams :: ·242 calorie.

(2) If 1 calorie : 3·073 ft.-lb. : ·242 calorie :: ·744 ft.-lb.

and by way of proof or corroboration we next find that 1 volt-ampere = ·2405 gram C heat units = ·737 ft.-lb.

We thus simply deduce the result, that 1 volt of power may be maintained by the expenditure of about ¼ calorie per second.

In *The Electrician*, April 15, 1887, p. 499, Mr. FitzGerald gives some kindred equations in absolute units upon the C.-G.-S. system. What that system is I do not know, nor do I care to know; but he wisely condescends to repeat them in our ordinary or practical units. He says, heat $= \frac{CE\theta}{4{\cdot}2}$ *calories*, also E (power) $= \frac{H \times 4{\cdot}2}{C\theta} =$ *volts*, or $E = \frac{H \times 4{\cdot}2}{96{,}600} = \frac{H}{23{,}000}$ *volts*. All this refinement is doubtless A B C to him, but it is not so to many ordinary students and workers; meanwhile, his $E = \frac{H \times 4{\cdot}2}{C\theta}$ *volts* really implies "that with unit current, in unit time, $\frac{1}{4{\cdot}2}$ calorie is expended for each volt, *i.e.*, about ·24 calorie."

I do not see that a more perfect corroboration could possibly exist; nor is it at all otherwise with Mr. J. T. Sprague, who has entertained the subject in his work on "Electricity" (2nd edition), where he shows that 23,287 calories, *continued* for 97,808 seconds, would equal ·238 calorie per second; which is another way of saying that "with unit current in unit time $\frac{1}{4{\cdot}2}$ calorie is expended for each volt," or, in either case, an expenditure of about ·74 ft.-lb. per second maintains 1 volt.

There is probably a simplicitly and definiteness about volts which is not well approximated by calories, and, if so, why all this furor of mistake to compare the two things? Calories depend so much both on the antecedents and consequents of a given reaction as to render its determination often a matter of great difficulty.

For the enlightenment of Mr. Swinburne it may be well to repeat with emphasis my remark that whenever moderns are impelled or necessitated to appreciate the *real* relations, they invariably do so by a "hocus pocus" arrangement, which virtually conforms to the old or equivalent view of things.

This is evaded by a flippant assumption that the two views are equally true, that mass 9 of water = 34,000, as mass 18 = 68,000; that one is as good and true as the other, but that the latter best suits the views of modern chemistry.

On the contrary, we maintain that the two things are *different*, in the sense, that one is *true*, where the other is fanciful hypothesis. Mr. Shaw and Lord Rayleigh find that *the same electrolysis* which deposits 1 of copper may also deposit 3·4 of silver.

Now *this ratio* is a fact in nature, and in accordance with all other chemical truth; but it necessitates the "hocus pocus" when the atomic weights *are supposed* to be as 63 to 108. It is precisely thus with Mr. Sabine, who found by *observation* a 10 per cent. enlargement of volume; but without the "hocus pocus" he could not have derived the same 10 per cent. from *calculation*.

These, however, are only faint ways of showing the validity of this contention as compared with the overwhelming evidence supplied by the widest assemblage of chemical facts.

Yours, &c., SAMUEL E. PHILLIPS, F.C.S.

NOTE ON THE REGULATION OF SERIES-WOUND TRANSFORMERS BY "INDUCTION-RINGS."

The method of regulating series-wound transformers, described in *The Electrician* of April 29th (in which lamps switched off are replaced by coils whose virtual resistance is equal to that of the lamps), will be found on examination to present some rather curious points. From the practical point

Digitized by Google

A circuit containing self-induction acts as if it had a larger resistance than its true one when a current is started in it, and a smaller resistance when the current is stopped. Hence, if balance be obtained with a Wheatstone bridge in the ordinary way, the fact of any of the arms possessing self-induction, or of any one of the arms having a condenser attached to it, will produce no effect on the balance if the battery circuit be rapidly made and broken, provided that the rapidity of make and break be not too great for the currents in the arms of the bridge to reach their steady values each time that the battery circuit is made, and to die away each time that it is broken. If the currents have not time to reach their steady value when the battery circuit is closed, and to die away when it is broken, then self-induction in any one of the arms will produce a disturbance in the balance; but such a method of measuring a coefficient of self-induction would lead to very complicated formulæ, and is not worth developing with the view of obtaining a simple method of measuring self-induction.

It therefore occurred to us to consider whether, without employing such rapid makes and breaks as would prevent the currents reaching their steady values, the self-induction of a circuit might not be made to act as an apparent steady definite increase of the resistance of that circuit which could be measured in the ordinary way with a Wheatstone bridge or differential galvanometer, and by this means the measurement of a coefficient of self-induction would simply resolve itself into the measurement of a resistance. And this problem we solved in the following way, in the spring of 1886:—

The coil, the coefficient of self-induction of which it is desired to measure, is placed in one of the arms of a Wheatstone bridge, the three other arms consisting of ordinary doubly-wound resistance coils possessing no appreciable self-induction, and not only is the battery circuit rapidly made and broken, but, in addition, after each closing of the battery circuit the galvanometer circuit of the bridge is either short-circuited or broken, so as to cut out the galvanometer, and after each breaking of the battery circuit the galvanometer circuit is either unshort-circuited or closed again, so that the galvanometer is now operative again. In this way all the successive impulses of the galvanometer needle that are produced on starting the current in the coil with self-induction produce their *cumulative* effects, but the successive impulses of the needle that, under ordinary circumstances, would be produced on the needle in the opposite direction are cut out. Hence the self-induction possessed by one of the arms causes that arm to apparently increase in resistance by a definite amount depending on the coefficient of self-induction and the number of operations performed per minute. This apparent increase of resistance produces a deflection of the galvanometer which can be noted, and its value ascertained by comparing it with the deflection produced with steady currents when one or more of the arms of the bridge is altered by a known amount, as in making the Rayleigh test described above. But since the necessity of having to read the deflection limits the speed of performing the double make and break operation, in order that the spot of light may not be sent off the scale, we soon replaced this comparative deflection *cumulative* method* by a much more sensitive *zero cumulative* method, and instead of reading the galvanometer deflection we re-establish the balance and bring the needle back to zero, by altering one or more of the arms of the bridge, as in making an ordinary resistance test with a Wheatstone bridge.

In our experiments we have also preferred the periodical short-circuiting of the galvanometer to breaking the galvanometer circuits, since, as there is a current flowing in the galvanometer when this operation is performed if the zero method be employed, the breaking of the galvanometer circuits would produce a spark which would make the calculations difficult, whereas, as will be seen, the periodical short-circuiting of the galvanometer produces an effect that can easily be taken into account in the mathematical investigation.

The measurement of a coefficient of self-induction in this way is extremely simple, because on the condition that the periodic time of our operation is not too short for the currents to become steady in the interval between the closing of the battery circuit and the short-circuiting of the galvanometer, and to die away in the interval between the breaking of the battery circuit and the unshort-circuiting of the galvanometer, we have shown that the following *remarkably simple* formula is very approximately true:—

$$L = T\sigma \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where L is the coefficient of the self-induction of the coil in ohm seconds, or earth quadrants, the commercial unit of self-induction, T the time in any one operation that the galvanometer is non short-circuited while the battery circuit is closed, and σ the apparent increase of resistance of the coil in ohms. It will be observed that when L is small the measured increase of resistance, σ, may be made quite large enough to be accurately measured by making T small. This may be done either by performing the operation rapidly, or, as will be seen later on, by altering the adjustment in the particular apparatus which automatically performs the required operation. *Hence this method is an extremely delicate one for the absolute measurement of a coefficient of self-induction, and the coefficient is expressed in its simplest possible form, namely, as the product of a time into a resistance.*

If instead of periodically cutting out the galvanometer circuit while the battery circuit is being broken, we cut it out while the battery current is being made, and allow the galvanometer to be operative while the battery circuit is being broken, the resistance of the coil possessing self-induction will apparently become less by a definite amount, and in this case σ will be the apparent diminution of its resistance, and T is the time the galvanometer is operative after the battery circuit is broken.

The first apparatus for enabling measurements of self induction to be made in this way was constructed in the spring of 1886, under the superintendence of one of our assistants, Mr. Mather. It consisted of a double commutator, shown in Fig. 1, the spindle S, to which the commutators were locked by the nut N, being rotated at any speed by a small electromotor not shown in the figure, to which was attached a Young speed indicator, which registered the speed of rotation at any moment. The brushes, B_1, B_2, b_1, b_2, were fixed to the baseboard and joined to the bridge, as indicated in the figure. When the double commutator was rotated by the motor (of which the speed was correctly adjusted by means of a Varley flexible carbon-resistance), the portion A B caused the battery circuits to be periodically made and broken, while the other portion, C D, periodically short-circuited and unshort-circuited the galvano-

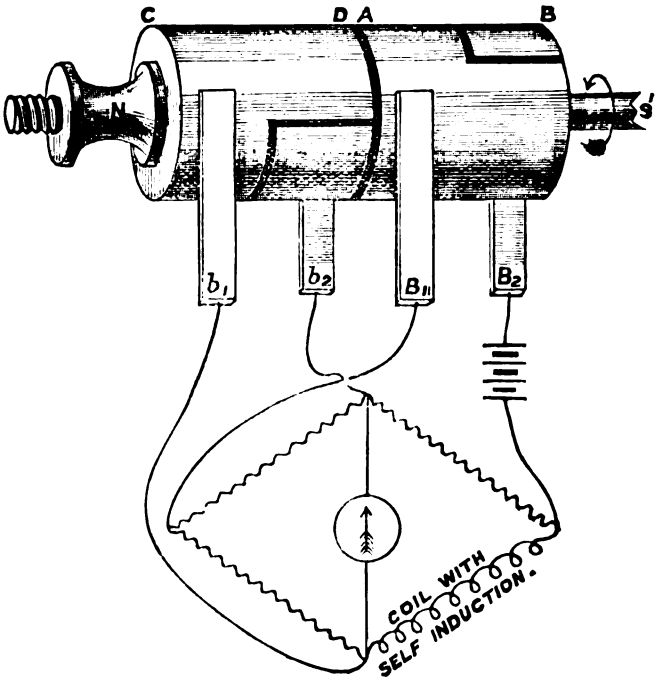

FIG. 1.

meter, so that the following cycle of operation, called for simplicity *one operation*, was performed any desired number of times per minute.

Battery Circuit.	Galvanometer Short Circuit.
Make.	While broken.
While made.	Make.
Break.	While made.
While broken.	Break.
Make.	While broken.

The time T in the formula given above is the interval that elapses in one rotation between the time when the continuous part of the commutator A B comes into contact with the brush B_2, and the time when the continuous part of the commutator C D comes into contact with the brush b_2. This time can be made shorter or longer by varying the speed of rotation, but it can also be varied by loosening the nut, N, and shifting one of the commutators round relatively to the other, and then screwing up the nut again. Indeed, it was for the purpose of enabling this adjustment to be easily made that double springs were in each case employed, instead of making one contact through the spindle.

At about this time—that is, in the summer of last year—we invited Mr. Sumpner, one of the third year students of the Central Institution, to experiment with this apparatus, and generally, by experimenting and by working at the subject mathematically, to find out the capabilities of this new method of measuring self-induction, also to see whether by possibly using the apparatus in some other way the method could be made even still more sensitive. We take this opportunity of thanking Mr. Sumpner for the energetic way in which he has worked at the subject, and for the very large number of experiments on the accuracy of various modes of measuring self-induction which he has conducted, with the occasional aid of two other of the third year students, Messrs. Rossiter and Watney.

* Since this paper was announced to be read, M. Lipmann has communicated to the French Academy a paper "Sur la Détermination du Coefficient du Self-induction," by MM. P. Ledeboer and G. Maneuvrier, describing a new method which these experimenters have devised. An examination of it, however, shows that it is identical with our *less sensitive* 1886 method. After giving some very accurate results that they have obtained by using the new method of testing, they say:—"Nous l'avons préferée d'ailleurs aux autres méthodes pour le mésure des faibles coefficients de self-induction, et notamment à la méthode de M. H. F. Weber (modification de celle de M. Hughes), parce qu'elle conduit à une formule très simple et qu'elle nécessite, en dehors du pont du Wheatstone, d'autre disposatif experimental qu'un interrupteur tournant."

The various methods of testing which Mr. Sumpner has employed, the mathematical development of the formulæ used by him in each case, and his general conclusions as to the accuracy of the various methods, are given later on in the Appendix; but one interesting result that he has arrived at may here be mentioned, viz., that although the apparatus has during the past twelve months been gradually totally altered in detail, the experiments have shown that the principle originally proposed for carrying out the measurement, requiring the cycle of operations given in the foregoing table to be periodically and rapidly performed, is the simplest and most accurate one to employ. One reason for the accuracy of the method is that neither commutator is in any one of the arms of the bridge, so that no ordinary change in the resistance of the contacts produced by oil or dust, &c., getting in between the springs and the rotary barrels can introduce any error into the test. Of course an actual failure of contact might lead a careless experimenter to a wrong result, but so might a disconnection in the battery or galvanometer circuit in an ordinary Wheatstone bridge, if the conclusion was drawn that, because there was no deflection on pressing down the key, balance had been obtained.

The first thing to be done after constructing the apparatus, was to ascertain what was the formula connecting the unknown coefficient of self-induction with the apparent increase of resistance of the coil, and the time in which the cycle of operations was performed.

This formula we calculated ourselves, neglecting the self-induction of the galvanometer, since we felt that its effect could not be serious. Mr. Sumpner, on the other hand, took up the complete problem, and we give his proof reduced to its simplest form, since, in addition to its application to the experiment in question, the calculation is interesting in connection with the problem of measuring the capacity of a condenser with a Wheatstone bridge and vibrating wippe, which will be found worked out by Clerk-Maxwell, without, however, any notice being there taken of the self-induction of the galvanometer, the effect of which, therefore, on the answer is not considered.

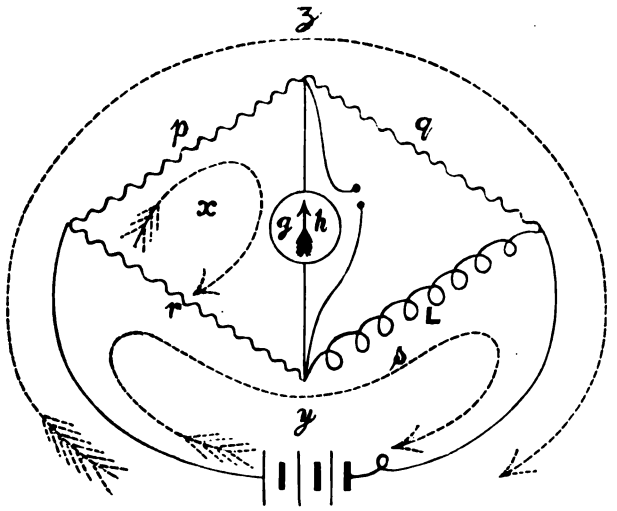

FIG. 2.

Fig. 2. shows the Wheatstone bridge, s being the resistance of a coil with a coefficient of self-induction L; p q and r are the resistances of the three other arms of the bridge when they are so adjusted that there is no deflection of the galvanometer on rotating the commutators at a certain speed. On rotating the commutators a current will sometimes pass one way through the galvanometer and sometimes the other, but with the particular speed of rotation p, q, and r are such that the total quantity passing through the galvanometer is nought. The resistance and coefficient of self-induction of the galvanometer are g and λ, and the electromotive force and resistance of the battery E and b. Then if x, y, z be the imaginary currents on the meshes,*

$$r(x-y)+p(x+z)+gz+\lambda\frac{dx}{dt}=0$$

$$b(y+z)+r(y-x)+sy+L\frac{dy}{dt}=E$$

$$b(y+z)+px\qquad+qz\qquad=E.$$

Eliminating y and z, we have

$$Ax+B\frac{dx}{dt}+P\frac{d^2x}{dt^2}+C\quad=0\quad\ldots\ldots\quad(2)$$

where

$$A=\begin{vmatrix} r+p+g & -r & p \\ -r & s+b+r & b \\ p & b & p+q+b \end{vmatrix}$$

$$B=\lambda\begin{vmatrix} s+b+r & b \\ b & p+q+b \end{vmatrix}+L\begin{vmatrix} p+g+r & p \\ p & p+q+b \end{vmatrix}$$

$$P=(p+q+b)L\lambda,$$

$$C=E(ps-qr).$$

* For the method of solving such problems by the employment of these imaginary currents, see a most interesting paper by Dr. Fleming, in the *Proceedings* of the Physical Society, Vol. VII., p. 215.

Integrating (2) we obtain

$$A\int x\,dt+B\int dx+P\int\frac{d^2x}{dt^2}dt+\int C\,dt=0\quad\ldots\ldots\quad(3)$$

The effect on the galvanometer needle may be divided into two parts—one, the first rush of electricity that occurs through it when the battery circuit is closed during the time the galvanometer is not short-circuited, and the diminution of this current through zero and its increase in the opposite direction until it reaches a certain definite value, when the currents in the arms of the bridge have become steady; the second, the dying away of this reverse current in the galvanometer while it is short-circuited. These two effects we shall consider separately.

To ascertain the amount of the first effect, we must integrate between t equals nought and t equals T, since, by hypothesis, T is the interval that elapses between the closing of the battery circuit and the short-circuiting of the galvanometer.

Integrating between these limits we have

$$\int_0^T x\,dt=Q_1,$$

where Q_1 is the quantity of electricity that flows through the galvanometer in the time T,

$$\int_0^T dx=-\frac{C}{A},$$

since this is the final steady value of the current x, which is nought at time nought.

Also $$\int\frac{d^2x}{dt^2}dt=\frac{dx}{dt}$$

and $$\frac{dx}{dt}=0 \text{ at time T},$$

since, by hypothesis, T is long enough for the currents to become steady. To find the value of $\frac{dx}{dt}$ at time nought, we have the fundamental differential equation for the current through the galvanometer

$$gx+\lambda\frac{dx}{dt}=V,$$

where V is the potential difference at the terminals of the galvanometer at any time. And since where t equals nought x equals nought, we have at time nought

$$\frac{dx}{dt}=\frac{V_0}{\lambda},$$

where V_0 is the value of the potential differential at the terminals of the galvanometer at time nought

and $$V_0=-\frac{Ep}{p+q+b},$$

since at time nought both x and y are nought, therefore at time nought

$$\frac{dx}{dt}=-\frac{Ep}{\lambda(p+q+b)},$$

and therefore $$\int_0^T\frac{d^2x}{dt^2}dt=-\frac{Ep}{\lambda(p+q+b)}.$$

Lastly $$\int_0^T dt=T,$$

therefore equation (3) reduces to

$$AQ_1-B\frac{C}{A}+P\frac{Ep}{\lambda(p+q+b)}+CT=0.$$

Next, let us consider the dying away of the current in the galvanometer after it is short cuited. We may now use simply the equation

$$gx+\lambda\frac{dx}{dt}=0,$$

if the resistance of the short circuit be very small compared with that of the galvanometer itself.

Multiplying by dt, and integrating from t equal T to t equal T', say the time the short circuit is removed, we have

$$gQ_2+\lambda\int dx=0,$$

where Q_2 is the quantity of electricity that passes through the galvanometer while short-circuited. At the moment after short-circuiting

$$x=-\frac{C}{A},$$

the steady value of the current, since the self-induction of the galvanometer prevents any instantaneous change in the current passing through it, and when t equals T' the current in the galvanometer is nought, since, by hypothesis, the time of short-circuiting T' - T is long enough for the current in the galvanometer to die away,

$$\therefore\int_T^{T'}dx=-\left(-\frac{C}{A}\right).$$

Now, in order that there may be no deflection of the galvanometer, we must have

$$Q_1+Q_2=0,$$

$$\therefore\frac{BC}{A_2}-\frac{P}{A}\frac{Ep}{\lambda(p+q+b)}-\frac{C}{A}T=\frac{\lambda}{g}\cdot\frac{C}{A}\quad\ldots\quad(3)$$

Digitized by Google

Let σ be the apparent steady increase of the resistance of the coil with self-induction (of which the ordinary resistance is s) produced by the rotation of the commutator at speed corresponding with the times T and T^1, then

$$p(s+\sigma)=rq,$$
$$\therefore C=-Ep\sigma.$$

Substituting this value for C, and for P its value $L\lambda(p+q+b)$ in equation (3), we have

$$L=\sigma\left(T+\frac{\lambda}{g}-\frac{B}{A}\right). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Now $\frac{\lambda}{g}$ and $\frac{B}{A}$ are usually small compared with T, therefore when this is the case

$$L=\sigma T,$$

the simple formula previously referred to.

Referring to Fig. 1, it will be seen if the brushes B_2 and b_2 touch over a small area, and if the centres of these areas are in a plane passing through the axis of rotation, that T is simply equal to

$$\frac{\text{angle between the slits in the two commutators}}{360\times\text{number of revolutions per second.}}$$

We may call

$$\frac{\text{angle between the slits in the two commutators}}{360\text{ deg.}}$$

the lead or l, and l will be equal to $\frac{1}{4}$, for example, when each of the cycle of operations given in the table last for one quarter of a revolution.

Introducing l we have, if σ be in ohms,

$$L=\frac{l}{n}\sigma \text{ second-ohms},$$

where n is the number of revolutions of the commutator per second, or

$$L=\frac{60\,l\sigma}{N}\text{ second-ohms} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where N is the number of revolutions per minute.

A large number of experiments were made in May 1886, with a solenoid of which the resistance was about 4 ohms at ordinary temperatures, to see how nearly the coefficient of self-induction determined by using the double commutator arrangement running at different speeds, and with different leads, agreed with the coefficient of self-induction determined by Lord Rayleigh's method, which gave 0 0215 second-ohm for the solenoid alone, and 0 517 second-ohm when a certain iron core was introduced into the solenoid.

The following are some of the results obtained with the solenoid without the iron core when the lead

$l=\frac{1}{12}$ about :—

N	$s+\sigma$	σ	$L=\frac{60\,l}{N}\sigma$
0	4·06		
660	6·70	2 64	0·0200
760	7·00	2·94	
860	7·50	3·44	0 0200
997	8·00	3·94	
1117	8·50	4 44	
1240	9·00	4·94	
1362	9·50	5·44	0·0200
1450	11·00	6·94	
1850	12·00	7·94	0·0204
2335	13·50	9·44	0 0202

Plotting these results on squared paper, we obtain the curve A A A (Fig. 3), the abscissæ representing the values of N, the number of revolutions per minute, and the ordinates the values of $s+\sigma$, the apparent resistances of the solenoid at the various speeds. This curve we see is a perfectly straight line, which means that the increase of resistance is proportional to the speed ; or, in other words, the approximate formula (5) for calculating L may be employed with *any* of the results, and the value of L so obtained from a few of the results is given in the last column of the preceding table. That we may use the approximate formula at all for L shows us that the term

$$\frac{\lambda}{g}-\frac{B}{A}$$

in the expression (4) is negligible in comparison with T ; and that we may use it even for the result obtained with the highest speed of rotation employed, viz., 2,335 revolutions per minute, shows us that $\frac{1}{12\times2335}$ minute, or about 0 0022 of a second, which is the time the galvanometer remains unshort-circuited after the battery circuit is closed, is long enough for the currents in the bridge to reach their steady value.

The values of the coefficient of self-induction obtained, 0 020, are approximately equal to 0·0215 second-ohm, the value obtained by Lord Rayleigh's method, and that they are not exactly the same arises from the difficulty, already referred to, of estimating the lead l accurately with the eye. This would not introduce any inaccuracy in the actual use of the instruments, since for a given adjustment of the relative positions of the commutators A B and C D in Fig. 1, the value of l is a constant, and this value would be determined once for all, not by the eye, but by an actual experiment made with a coil of known self-induction. We were not, however, calibrating the instrument on the assumption that the approximate formula (5) was true, but using the instrument to see how nearly (5) might be employed. In our experiment l was probably not $\frac{1}{12}$ exactly, but more nearly $\frac{1}{11}$.

Experiments were now made with the lead l, equal about to 0·3.

$l=0·3$ about

N	$s+\sigma$	σ	$L=\frac{60\,l}{N}\sigma$
0	4·06		
770	5·00	0·94	
1120	5·50	1·44	Mean value,
1600	6·00	1·94	0·0218 ohm-second.
2000	6 50	2 44	
2410	7·00	2 94	
2860	7·50	3·44	

These results when plotted give the straight line B B B. Instead, therefore, of calculating the value of L from several of the results, as before, we may more accurately determine it from the point at the end of this line corresponding with a speed of 3,000 revolutions per minute, and an apparent resistance of 7·7 ohms, that is an apparent increase of 3·64 ohms. This gives for L the value 0·0218 second-ohm, also not differing much from the true value 0·0215 second-ohm, considering that the exact value of the lead was not known.

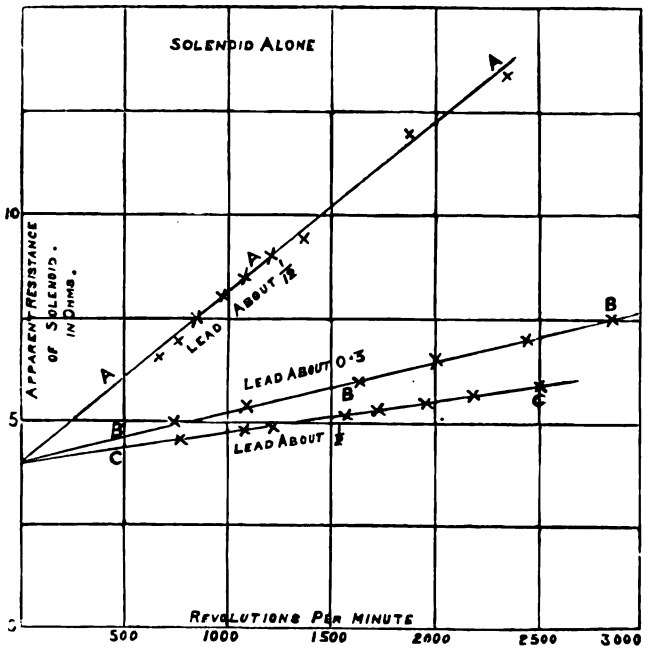

FIG. 3.

Lastly, experiments were made with a lead of about $\frac{1}{2}$, with the following results :—

$l=\frac{1}{2}$ about

N	$s+\sigma$	σ	$L=\frac{60\,l\,\sigma}{N}$
0	4 1		
820	4·7	0 6	0·0219
1100	4 9	0·8	
1240	5·0	1·0	0·0217
1560	5·2	1·1	
1700	5·3	1·2	0·0212
1950	5 5	1·4	
2220	5·7	1·6	0 0216
2500	5·9	1 8	0 0216

Here again the points all lie very nearly in the straight line C C C, and the values given in the last column, calculated from some of the points, are all nearly equal to one another and to the true coefficient of self-induction of the solenoid.

It is clear, therefore, that with speeds up to 3,000 revolutions per minute and higher, and with leads varying from $\frac{1}{12}$ to $\frac{1}{2}$, any single experiment correctly made gives the true value of the self-induction by the use of the simple formula

$$L=\frac{60\,l}{N}\sigma.$$

We see from the formula, and from the experiments which substantiate it, that the smaller the lead and the higher the speed of rotation of the

Digitized by Google

commutating arrangement, the larger is the value of apparent increase of resistance—that is, the more sensitive is the test.

The iron core was now inserted in the solenoid, and a series of experiments made with leads equal to $\frac{1}{12}$, $\frac{1}{6}$, $\frac{13}{36}$, $\frac{17}{36}$, in the respective sets of experiments. The results are shown by the curves D D D, E E E, F F F, G G G. It will be observed that, although the speed of rotation of the commutating arrangement did not exceed 680 revolutions per minute, the observations do not lie even approximately in a straight line, until the lead $\frac{17}{36}$ is employed, and even when the last lead $\frac{17}{36}$ is used there is still curvature in the line. This great difference between the curvature of the lines for a range of even slow speeds when the iron core is introduced, and the perfect straightness of the lines beyond the highest speed, 2 800 revolutions per minute, employed with the solenoid alone, arises from the coefficient of self-induction of the solenoid, with the iron core inserted, being about twenty-five times as great as the self-induction of the solenoid alone. Hence the smallest interval, T, between the closing of the battery circuit and the short-circuiting of the galvanometer that can be employed is much larger when the iron core is inserted than when the solenoid alone is used. Consequently the lead must be large or the speed must be slow for the results to lie in a straight line. The curve D D D, obtained with the lead of about $\frac{1}{12}$, is too far from straight for any portion of it to be used in calculating the coefficient of self induction, with the simple formula—in other words, so small a lead was unsuitable to be used. The greater part of the next curve, E E E, is also too far from straight to be used, but the first observation, corresponding with a speed of 156

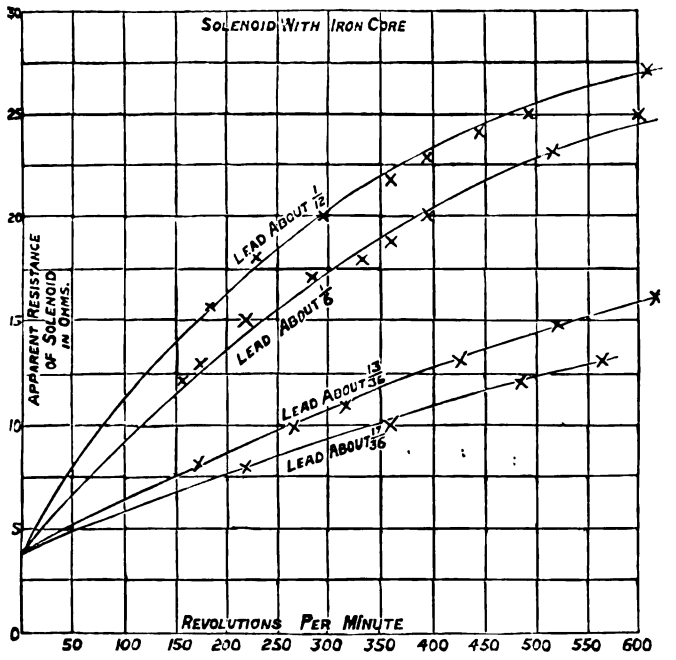

FIG. 4.

revolutions per minute and an apparently increasing resistance of 8 ohms, is on a portion of the curve sufficiently straight to give an answer not much smaller than the truth. The result so obtained is

$$L = \frac{60 \times \frac{1}{6}}{156} \times 8$$

$$= 0{\cdot}513 \text{ second-ohm},$$

which is not very much less than the true value of the coefficient of self-induction of the solenoid with the iron core, as determined by Lord Rayleigh's method, which, as before mentioned, gave 0·517 second-ohm.

With the lead of about $\frac{13}{36}$, the lowest speed at which an observation was taken was 170, corresponding with an apparent increase of resistance of 4 ohms. This gives

$$L = \frac{60 \times 13}{170 \times 36} \times 4$$

$$= 0{\cdot}510.$$

If we take the next speed, 260, corresponding with an increase of resistance of 6 ohms, we find L equal to 0·500.

The last curve G G G, obtained with the largest of the leads, about $\frac{17}{36}$, is the one that, being straightest, will probably give the best results, but as even this is not quite straight we must expect to obtain slightly too low a value. The two first observations correspond with speeds of 220 and 355 revolutions per minute, producing an apparent increase of resistance of 4 and 6 ohms. The values of L obtained from these results are 0·515 and 0·482 second-ohm, from which we should conclude that the true answer was a little higher than 0 515 second-ohm, and this we know is correct, as the true answer is 0·517 second-ohm.

That it is necessary to employ only slow speeds when a large coefficient of self-induction is being measured is no disadvantage, because when the self-induction is large the apparent increase of resistance at even slow speeds is great, and so can be accurately measured.

(To be continued.)

SOCIETY OF TELEGRAPH-ENGINEERS—STUDENTS' MEETING.

The first students' meeting was held in the Society's Library on Thursday, the 5th inst., Prof. W. E. Ayrton, F.R.S., in the chair. Prof. Ayrton briefly addressed the meeting, stating the objects of such meetings, and expressing his warm sympathy with the movement. Mr. J. Rance then opened the discussion upon Dr. Thompson's "Telephonic Investigations," and was followed by Messrs. A. H. Bate, A. C. F. Webb, Wordingham, E. Thomas, and Cooper. Prof. Ayrton replied to several questions, and closed the discussion.

A vote of thanks to Prof. Ayrton terminated a very successful meeting.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The twenty-seventh ordinary general meeting of shareholders in this Company was held at Winchester House, 50, Old Broad-street, on the 11th inst. under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting, and the minutes of the last general meeting, which were approved by the present meeting and signed by the Chairman.

The CHAIRMAN having stated that that was the twenty-seventh occasion within the last fourteen years upon which his present duty had devolved upon him, continued: It is rather difficult to avoid monotony in discharging this duty on so many successive occasions. However, gentlemen, the monotony has not been altogether of a disagreeable character. I think there have been in the reports and addresses which I have had the honour to make to you elements which have rendered the monotony satisfactory or at least palatable to you. I remember that in the early days of our enterprise our proceedings were somewhat diversified by a not unnatural expression of impatience that our undertaking had not at once realised all the anticipations formed of it. However, that is now a matter of history, for of recent years our proceedings have been tolerably amicable between the Directors and the shareholders, and I think the state of the room on the present occasion proves that the shareholders have no want of confidence in the management of the Directors. Those of you who have taken the trouble to read the present report—which is a condensed history of the transactions of the Company for the last six months—will see that the satisfactory elements to which I have alluded as existing in former reports are not wanting on the present occasion. I am happy to say that we are able to report that all your plant is in excellent condition. We have had during the last six months a complete immunity from any casualty, and our traffic has shown a substantial increase both on the previous half-year and on the corresponding period of the previous year. I may incidentally mention that that satisfactory increase of traffic is still going on, and that up to the present time we are receiving considerably more than we obtained last year. We have been able to pay our usual dividend and to carry a very substantial sum to the reserve fund, and also to carry forward a considerable sum to the current half-year's accounts. Well, under those circumstances I do not think the resolution that I have to propose requires any very great eloquence or argument on my part to enforce it There are one or two incidental circumstances to which I would venture just to allude. We have been threatened with competition in several directions. These threats have not as yet assumed what I may call a tangible form. All I can say about them is that we are exercising the greatest vigilance as to those threatened attacks, and your Board will take such steps in the event of their becoming tangible as they may consider necessary to support the interests of the Company. You are aware that for a long period past we have been engaged in negotiations for strengthening—as I stated on a former occasion—our position in Brazil. Those negotiations have as yet led to no practical result; but we are not without hope that they may do so, and in the meantime we must ask the continued forbearance of the shareholders, for it will be obvious to you that to disclose our hand, and show what our operations are in the midst of a negotiation, would not be a wise or a useful course for us to pursue. I do not think there is any other circumstance that I need allude to, and I beg leave to propose that the report of the Directors and the accounts to the 31st December, 1886, now submitted, be approved and adopted.

Sir JAMES ANDERSON: I beg leave to second that.

The CHAIRMAN, in answer to a question, said that what he had referred to as competition was that there were several proposals to construct new lines which would practically compete with the Company. However, as he had already stated, they had not yet assumed any very decided form. The resolution was then carried unanimously.

On the motion of Mr. GRIFFITH, seconded by Mr. NICOL, a cordial vote of thanks was passed to the Chairman and the Directors.

The CHAIRMAN, in acknowledging the vote, stated that the Directors would continue to do their best, as in the past, to promote the interests of the Company.

The proceedings then terminated.

Submarine Cables Trust.

The sixteenth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices of the Trust, Winchester House, No. 50, Old Broad-street, on Wednesday, the 11th inst., Mr. John Pender presiding.

The SECRETARY (Mr. Lewis Wells) read the notice convening the

Digitized by Google

meeting, and the minutes of the previous meeting, which were confirmed and signed by the Chairman as correctly entered. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: On referring to the accounts, it will be seen that our revenue for the past financial year amounted to £14,528, against £21,826 in the previous year. As stated in the report, this is mainly owing to the falling off in the dividend paid by the Anglo-American Company, from whom we received only 5s. per cent., against £1. 5s. in 1886; but we have also had diminished returns from our other investments—the Eastern Company has only paid 5½ per cent, against 6 per cent., and the Eastern Extension Company 6 per cent., against 7 per cent. It will be observed that we brought into the past year's accounts £1,949, and carry forward a balance of only £95. We have, in fact, divided our revenue up to the hilt, not even retaining in hand sufficient to meet the expenses of the current half year. Knowing that the interest on the coupons was cumulative, the trustees wished to give the certificate holders as much as possible on account of the April coupon, as they did not see their way to pay the balance of 30s. before October 15th. The expenses of the Trust are £1,359, against £1,349, or only £10 more than last year, in spite of the extra cost of stationery and clerical labour in having to stamp the coupons in the office here—a work which was not necessary when the coupons were paid in full by the bankers. For the current year we estimate that we shall receive at least 1 per cent. from the Anglo-American Company, against 5s. last year, while it is hoped that the Eastern Extension Company will again be in a position to pay a dividend of 7 per cent. In this case, although we shall not be able to pay our coupons in full, we shall give the certificate holders a fair return on their investment. There can be no doubt, gentlemen, that the American cable war of rates must terminate some time; as to when it will terminate I am not prepared to say, but having a strong belief that there is a period when it is positively throwing away money to continue such a war, I hope the termination is perhaps nearer than at present we should be disposed to expect. The reduction of returns, and therefore of dividend, on the part of the Eastern and Eastern Extension Companies arose through very material reductions made in the tariffs at the Berlin Conference. That reduced the income for the moment of these companies by something like £100,000. Of course it takes time to recoup this loss, and temporarily their dividends had to suffer, and consequently we have had to suffer with them. There was a Colonial Conference the other day, in which telegraphs were discussed. The result of that conference is, I think, to leave us in a better and stronger position than we have occupied for a very long time. I am therefore hopeful that before I have the pleasure of seeing you again the traffic will continue to show that vitality which has hitherto been so remarkable in telegraphs, and that we shall be able to go back both in the Eastern and Eastern Extension to our old dividends, and I hope also that the war of rates to which I have referred will be terminated in the interests of the Anglo-American and all concerned. Altogether, I think the prospects are good for those who hold in this Trust, and that we shall before long be in a better financial position than we are in to-day. With these remarks, I beg to move:—"That the report and accounts of the Trustees, now submitted to the meeting, be approved and adopted."

The Right Hon. Viscount MONCK seconded the motion, which was carried unanimously.

The CHAIRMAN: The next resolution is one that rests with the shareholders, and I shall be pleased if any of them will move it.

Dr. HATHAWAY: The resolution which has been put into my hands is: "That Messrs. John G. Griffiths and Mr. John Gane be re-elected auditors of the Trust for the current year, at a remuneration of £25 each," which I beg to move.

Mr. DAVIES seconded the motion, which was agreed to unanimously.

On the motion of Mr. DAVIES, seconded by Dr. HATHAWAY, a vote of thanks to the Chairman and Directors was cordially passed.

The CHAIRMAN: Gentlemen, we are always pleased to have our services recognised by the shareholders on occasions of this kind. We do our very best for your interests, and when that best is appreciated by you it makes us still more earnest to carefully look after your affairs. As I said before, I hope by the time we shall meet you again we shall be able to report a better state of things.

The proceedings then terminated.

West India and Panama Telegraph Company (Limited).

Report of the Directors to be presented to the twentieth ordinary general meeting of members, to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 18th inst., at 12 o'clock:—

The amount to credit of revenue is £37,930. 18s. 11d., and the expenses have been £27,934. 18s. 5d., leaving a balance of £9,996. 0s. 6d. which, with the balance of £2,292. 13s. 0d. brought from last account, makes a total of £12,288. 13s. 6d. with which it is proposed to deal as follows:—

Payment of 6s. per share on account of arrears of dividend on the first preference shares	£10,368	18	0
Balance to current half year's account	1,919	15	6
	£12,288	13	6

The traffic receipts for the six months show an increase of £147. 12s. 3d. as compared with the corresponding period. The expenses on account of repairs of cables have been exceptionally heavy during the half year, amounting to £4,800 in excess of the corresponding half. Both vessels have been more continuously engaged. The Jamaica-Colon section, referred to in the last report, was repaired on the 24th December after prolonged operations, rendered extremely costly and tedious by the great depth of water and the rocky nature of the sea-bed. The cable was eventually recovered from a depth of 1,613 fathoms. After completing this work the ss. "Grappler" resumed operations on the original (duplicate) Jamaica-Porto Rico section, but had to be recalled in order to proceed with other repairs. The Holland Bay-Ponce cable failed on the 30th ult., but was repaired on the 7th inst. The "Grappler" will now be ordered home, and will return to the West Indies with 250 knots of deep sea cable referred to in the last report.

The attention of the Board has been directed to a proposal which has been submitted to the French Chamber of Deputies by the Minister of Posts and Telegraphs, to authorise the guarantee of a gross revenue of £40,000 per annum for the construction of a cable between Para (Brazils) and New York, touching, among other places, at the French Islands of Martinique and Guadeloupe, which have been connected with the telegraphic systems of the world for the past 16 years by means of this Company's cable. The Directors have addressed communications to the French Government, pointing out the inevitably disastrous financial results of such an undertaking, and the inadequacy of the advantages expected, to justify so large a liability. A final decision has not yet been arrived at.

Of the £50,000 Six per Cent. Debentures which fell due on the 31st December last, £37,900 have been extended for a further term of five years at 5 per cent. per annum. The balance of £12,100 is still for disposal. In accordance with the Articles of Association, Sir James Anderson and William Andrews, Esq., retire at this meeting and offer themselves for re-election. John George Griffiths, Esq., the auditor, also retires and offers himself for re-election.

CITY NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 6th inst. amounted to £4,001.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company for April amounted to £20,320. From January 1 to April 30 they were £81,520, and for the corresponding months in 1886 and 1885 £78,480 and £89,200 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 6th inst. were £3,322.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 30th April are £3,156, as compared with £2,467 in the corresponding period of 1886.

NOTICE OF REMOVAL.—The Direct Spanish Telegraph Company inform us that the general offices of this Company have been removed to Winchester House, 50, Old Broad-street, E.C.

NOTES.

INTERRUPTION OF A FRENCH CABLE.—The cable between Porto-Rico and the Antilles is interrupted.

FIUME.—The port and town of Fiume are to be lit by electricity; power will be obtained from the River Fiumera, at a point some miles from the town.

TUNNEL LIGHTING.—The Hoosac Tunnel, near Boston, U.S., is to be lit throughout by Westinghouse transformers. The tunnel is 5½ miles in length.

CENTRAL LIGHTING STATIONS IN AMERICA.—The number of central electric lighting stations in full operation at the present time in America is given as 426.

WATERFORD.—Messrs. Laing, Wharton and Down have obtained the contract for lighting the streets of this town with arc lamps. The Thomson-Houston system will be employed.

CONTRACT OPEN.—Tenders are being asked for the lighting of the town of Port Louis in the Mauritius; no particular method is stipulated for. Further information may be obtained from the town clerk.

MADRID.—The *Imparcial* states that efforts are being made to arrange for the lighting by electricity of the grounds of the forthcoming Philippine Exhibition at Madrid. An installation of at least 6,000 lights is spoken of.

SHIP LIGHTING.—The North of Scotland and Orkney and Shetland Steam Navigation Company's new steamer, "St. Sunniva," has been fitted with an installation of 136 lamps by Messrs. J. D. F. Andrews and Co., of Glasgow.

"ELECTRO-DEPOSITION."—We have received from Messrs. Crosby Lockwood and Co. a copy of the second and revised edition of the work by Mr. Alexander Watt on "Electro-Deposition: A Practical Treatise on the Electrolysis of Metals, with several chapters on Electro-Metallurgy."

ORDERS FROM INDIA.—The Gülcher Company have, we hear, received orders for three installations for lighting palaces in India. The present order consists of one 100-light installation, and two 500-light installations, with engines, boilers, dynamos, accumulators, and fittings complete.

"THE SPECIALIST SERIES."—We have received from Messrs. Whittaker and Co. a copy of the second edition of the "Specialist Series" volume on "Magneto and Dynamo Electric Machines." This edition contains a preface and an additional chapter on the latest types of machine, by Mr. W. B. Esson.

"THE STORAGE OF ELECTRICAL ENERGY."—We have received from Messrs. Whittaker and Co. a copy of Mr. Bedford Elwell's translation of the collected edition of Gustave Planté's papers, entitled "The Storage of Electrical Energy, and Researches in the Effects created by Currents combining Quantity with High Tension."

"ELEMENTARY PRACTICAL PHYSICS, VOL. II.: ELECTRICITY AND MAGNETISM."—We have received from Messrs. Macmillan and Co. a copy of the second volume of the Owens College series of "Elementary Practical Physics," being the volume on "Electricity and Magnetism," by Prof. Balfour Stewart, F.R.S., and Mr W. W. Haldane Gee, B.Sc.

OPENING OF THE PARIS-HAVRE TELEPHONE LINE.—On Sunday week the telephone line between Paris and Havre was opened for the public service. The distance is about 110 miles. At present communication can only be obtained between the Bourse at Paris and the Central Exchange at Havre. The tariff has been fixed at the rate of 1fr. for five minutes' conversation.

MEXICO.—We learn from the City of Mexico that Commissioners of the State of Zacatecas are travelling in America studying the telephone, telegraph, and electric lighting systems of the large cities there. After inspecting the American cities, the commissioners will sail for Europe for the same purpose. They are generally authorised to examine all inventions and improvements in electrical apparatus.

SLATE CUT-OUT FRAMES AND SWITCH BLOCKS. — Mr. Rashleigh Phipps sends us a sample of his cut-out blocks and covers, made entirely in slate. The advantage, and in many cases the necessity, of using non-inflammable material for the support of fusible cut-outs has long been recognised, and we have seen no material that fulfils the purpose better than slate. These cut-outs are manufactured in all sizes to suit wood casing.

HAMBURG.—The municipality of Hamburg has appointed a committee to consider a proposal for undertaking electric lighting by means of transformers, and in connection with the gasworks it already owns. The capital outlay involved in the scheme under consideration amounts to £50,000. If it is decided to carry out the work the contract will, it is understood, be placed in the hands of Messrs. Schwartzkopf, of Berlin.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—The next meeting of this society will be held at 25, Great George-street, S.W., on Thursday, May 26th, at 8 p.m, when a paper on "Underground Telegraphs" will be read by Charles J. Fleetwood, member, followed by the paper on "Driving a Dynamo with a very Short Belt," by Profs. W. E. Ayrton, F.R.S., and John Perry, F.R.S., which was adjourned from the last meeting.

THE ELECTRIC LIGHT IN THE HOUSES OF PARLIAMENT.—In the House of Commons, in reply to Dr. Tanner, Mr. Plunket (First Commissioner of Works) said that he was deterred by the large expenditure from proposing the adoption of anything like a general system of electric lighting for the House and its offices, but he had directed the preparation of a complete scheme and estimate should the House be disposed to sanction the large expense.

LIGHTING OF THE LYCEUM THEATRE AT EDINBURGH.—The Lyceum Theatre at Edinburgh has been supplied with 200 Victoria lamps of 10 and 17 candle-power, for which current is generated by Victoria dynamos and a Raworth engine. The plant has been erected under the superintendence of Mr. Geipel, district manager of the Anglo-American Brush Corporation. Outside the theatre an arc lamp of 4,000 candle-power is hung, and is run on the same circuit as the incandescents.

PADUA.—The town of Padua supports a telephone exchange which numbers 232 subscribers, and at the low rate of £6 per annum managed last year to pay a 6 per cent. dividend, and carry forward a substantial sum. All the wires are of silicium bronze. The communications in 1886 numbered on the average 738 daily. It appears, however, that the Telephone Company of Milan claim to possess the sole right to the use of the Bell-Blake instruments, and have served a notice to that effect upon the Padua Company.

NARROW ESCAPE OF EDISON.—An American journal says:—"The safe arrival of Mr. T. A. Edison, Mr. E. T. Gilliland, and the other members of their party in this city on May 1st was the occasion of their receiving numerous congratulations over their very narrow escape from drowning on Thursday, 28th April. The entire party of eight persons were standing on a pier at Kissimmee Springs, two miles from Barlow, in Florida, when the pier collapsed and precipitated all the party except

Digitized by Google

Mr. Edison and Mrs. Gilliland into the water, which was eight or ten feet deep." Fortunately no lives were lost.

CITY AND GUILDS OF LONDON FINSBURY TECHNICAL COLLEGE "OLD STUDENTS'" ASSOCIATION.—At the last meeting of the Finsbury Technical College "Old Students'" Association, Mr. John Rance, from the Central Institution, read a paper on "Electric Railways." The relative advantages and disadvantages of battery and conductor systems were pointed out, and the efficiency of reversible batteries discussed. The paper concluded with a short description of the various lines now in operation and in process of construction, and tables were given showing the relative cost of electric and horse traction. Altogether the subject was very thoroughly treated, and induced an animated discussion.—At the same meeting Mr. Howard Swan read a short and appropriate paper on "Taking Lecture Notes."

THE TELEGRAPH SERVICE.—In the House of Commons on Tuesday last the Chancellor of the Exchequer, in reply to Sir W. Harcourt, said that the net revenue of the Post Office for the year 1881 was £2,586,436, and the estimated net revenue for the year 1887 was £2,400,000, showing a decrease of £186,000. In 1881 the net revenue from the telegraphs was £413,000. In 1886-7 there would be a deficiency of £223,000, so that in six years there was a falling off in net revenue of £536,000. This was without taking into account the interest on the purchase money of the telegraphs, which was £326,000. If that was added there would be a deficit on the telegraph service for 1886-7 of £549,000. The falling off was due not to diminished receipts, but to the additional expenditure, especially that incident to the parcels post and the introduction of sixpenny telegrams.

ARC LAMPS AT THE NEWCASTLE EXHIBITION.—At the opening of the Newcastle Exhibition on the 11th inst. it was noticed that the arc lamps in the gardens were very unsteady. We understand that this was due to the contractors being late with their work, so that there was no opportunity of regulating the lamps prior to the opening night; in fact, many of the lamps were only hung the same day. As the lamps have been properly regulated they have become perfectly steady, and those in the engine room and north gardens are now burning well, and there is every reason to believe that the installation will be perfectly satisfactory as soon as the contractors have had time to adjust every lamp for its work. Had the installation been completed a week before the opening of the Exhibition the flickering noticed would no doubt have been avoided, and it is certainly unfortunate that this was not done.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—The following is the programme of the session of the American Institute of Electrical Engineers, which is being held during the present week:—Papers will be presented on "Storage Batteries," by Mr. E. P. Roberts; "Results with Hard Drawn Copper Wire," by W. Maver, jun.; "Novel Phenomena in Secondary Generator Systems," by Prof. Elihu Thomson; "Installation of Electric Lighting Plants," by Mr. J. A. Powers; "Electric Lighting in Trains," by Mr. J. Wetzler and Mr. T. C. Martin; "Note on the Differing Temperature Coefficients of the Different Coils of a Fine Rheostat," and "Note on the Change from Negative to Positive of the Temperature Coefficients of some Carbon Filaments," both by Prof. W. A. Anthony; and "The Best Ratio of the Section of the Core of the Gramme Armature to the Section of the Field-Magnets," by Mr. D. C. Jackson, of Cornell University.

TEMPORARY INSTALLATION AT BRIDGWATER.—The *Bristol Times and Mirror* of May 16 says: "Upon the occasion of the visit of the Somerset Agricultural Association to Bridgwater last week, very material aid was rendered to the decorations, which were carried out on a large scale, by the use of the electric light. Messrs. King, Mendham and Co., of Bristol, were able at one day's notice to brilliantly light up a portion of the show by means of arc lamps, the dynamo being driven by a portable engine in a yard at some distance from where the lamps were suspended. As was to be expected, the light proved a great attraction to the country visitors, and many came in to the show having seen the glare of the light from a distance of two or more miles. The light was in every way a success, and the manner in which the work was carried out reflects great credit upon the firm, considering the extremely short notice they received at which to undertake it."

THE CALCULATION OF WORK DONE BY AN ALTERNATING E.M.F.—In another column will be found an interesting communication relating to the work done by an alternating E.M.F. in a compound circuit, the numerical data being taken from Messrs. Sharp and Kent's system of regulating series-wound transformers by means of "induction-rings," which we describ d in a recent issue. The calculation affords a good illustration of the immense difference between alternating and continuous E.M.F.'s as regards the energy expended. It is shown, for instance, that in a particular case, while both total current and E.M.F. in the secondary circuit remain constant, the consumption of energy may be caused to vary between 1,000 watts and 6·24 watts. This affords an excellent illustration (and one which should be very beneficial to those electricians who have not yet taken the trouble to make themselves acquainted with the laws of alternating currents) of the necessity for getting rid of the idea that the product E C represents watts when talking of alternating currents. The writer proceeds to show that in the same circuit, if the E.M.F. were continuous instead of alternating, instead of 6·24 watts, work would be done at the rate of 21·5 horse-power.

THE SCHOOL OF ELECTRICAL ENGINEERING AND SUBMARINE TELEGRAPHY.—The managers of this school, Messrs. W. Lant Carpenter and L. Drugman, inform us that they have just received from Mr. H. R. Kempe, of the engineer-in-chief's office, General Post Office, who undertakes the duties of external examiner in electrical engineering, a very satisfactory report on the results of the Easter examination for the vellum certificate of the school. This certificate is granted only to those pupils who get seventy per cent. of the marks, both in the theoretical and in the practical questions, and who have also passed the examination in the course of lectures on mechanical engineering. Certificates were awarded to twelve out of eighteen pupils who presented themselves from the class of the senior instructor, Mr. H. D. Wilkinson. The following is a list of their names and mark percentages:—B. S. Giles, 96·66; H. O. Holford, 96·66; T. D. Clapham, 93·33; W. J. Walters, 90·66; W. A. Purdom, 90; S. H. Lury, 89·33; E. G. Tidd, 88; G. Gregg, 88; F. W. M. Chapman, 87·33; P. J. Pringle, 85·33; A. W. Kingham, 76·66; J. R. Cotton, 74. All these gentlemen passed in electric lighting and transmission of power; three of them, Messrs. Gregg, Purdom, and Tidd, passed also in telegraphy and telephony.

ATTENDING CHURCH BY TELEPHONE.—We learn from a local paper that at the National Telephone Company's offices, Sheffield, last Sunday morning and evening a number of ladies and gentlemen listened to the service held at St. Paul's, Manningham, near Bradford, to which church the telephone wires had been extended. The voluntaries were exceedingly good. The anthem in the morning, "Where withal shall a young man?" by Sir G. J. Elvey, and in the evening the "Motet,"

Digitized by Google

"Oh God, when Thou appearest," by Mozart, were most distinctly heard, and the Sheffield audience more than once expressed their high appreciation of the skill of the organist (Mr. J. H. Rooks) and the singing of the choir. The tenor's voice was exceptionally fine. The preacher both morning and evening was the Rev. F. Hill, M.A., Rector of St. Luke's, Miles Platting. At the conclusion of the morning and evening services, Mr. Swithinbank, the company's manager at Huddersfield, and Mr. Young, inspector there, played at their residences several sacred tunes on the piano and harmonium respectively, which were distinctly heard by the audience at Sheffield. Conversation was also carried on in ordinary tones with Manchester, Preston, Burnley, Leeds, Huddersfield, and other towns, and in each case the articulation was as clear as if talking over a local line. Telephone communication between Sheffield, Manchester, Leeds, and other large centres, although not taken so much advantage of in Sheffield as in other towns, will in the near future prove invaluable to the commercial community. Mr. Northam, the Sheffield district manager, was warmly thanked by his congregation for the privileges granted them on Sunday.

COUNTRY HOUSE LIGHTING.—The Gülcher Electric Light and Power Company have completed the lighting of Mr. Neville's country house at Elsted, near Petersfield. The installation, which has been working satisfactorily for some time, has been carried out in the following manner:—The plant consists of a 2 horse-power Spiel petroleum engine, made by Messrs. Shirlaw and Co., of Birminghnm, and drives on to a No. 1 Gülcher shunt-wound dynamo machine. The dynamo charges a battery consisting of 27 Elwell-Parker 15 plate cells. A Mountain improved switch-board is placed by the dynamo machine, and is used for charging and discharging, running the dynamo and accumulators together in case of emergency, or running the lamps direct from the dynamo. A 5-contact switch is also provided on the same slate slab for adding extra cells as the E.M.F. falls, and the volt and ammeters with measuring plugs are arranged so that by inserting or withdrawing a plug the E.M.F. can be measured. The current from the dynamo room is led to the house by a pair of 7-15 cables, made by Messrs. Callender and Co. In the hall special hammered iron brackets have been used, in order to lend themselves to the character of the surroundings. In the bed rooms special raising and falling pendants, designed by Mr. Mountain, are used. Throughout the house the shades are of cut glass. The Gülcher Company adds:—"This installation is, we believe, one of the first where a Spiel petroleum engine has been used for private house lighting, and the result, as far as experience has shown, leads to the conclusion that they are admirably adapted for this purpose, and should be very largely used in the future."

CONVERSAZIONE.—The first *conversazione* of the Royal Society for the season took place last Wednesday evening at Burlington House, when Prof. Stokes (the president) received a numerous and brilliant assembly. The display of scientific apparatus on this occasion was specially interesting. Among physical appliances one which attracted much attention was shown by Prof. Rücker, F.R.S., explaining, by reflection on a screen, the use of Newton's famous rings in testing the expansion of metals by heat. By this beautiful contrivance, which Fizeau has employed, effects can be rendered visible which must be almost infinitesimal in amount. In the adjoining section Mr. C. V. Boys explained a mechanism for shooting threads of glass, emerald, and other substances melted in an oxyhydrogen flame, and attached to an arrow projected from a cross-bow. By this means he drew out filaments of incredible tenuity, quartz for example, so fine that the thinnest parts are beyond the power of any microscope to define. Dr. Marat, F.R.S., had at work in the reading room an instrument for speedy volumetric measurement of carbonic acid, where also Prof. Unwin, F.R.S., exhibited instruments for measuring extensions and compressions in materials subjected to stress to the nicety of the one hundredth thousandth part of an inch. In the principal library Mr. Norman Lockyer displayed a number of interesting photographs of the solar spectra; the Earl of Rosse, sketches of Jupiter and Mars; Prof. Ewing, earthquake records produced by the seismograph; Prof. the Rev. C. Pritchard, F.R.S., star-photographs; and Profs. Ayrton and Perry, the "Secohmmeter." In the department of biology, Mr. Edgar Crookshank, Dr. Klein, and Prof. Marshall Ward showed under the microscope a large number of those micro-organisms which produce disease in men, animals, and plants.

THE ELECTRIC LIGHT IN CHELSEA.—At the meeting of the vestry, on Tuesday, Mr. Mossop, the chairman of the Electric Light Committee, in moving the recommendation of the committee that the offer of the Cadogan Electric Light Company, in which they agree, in the event of the Vestry granting permission for overhead wires, to be bound by all the clauses both of the order and the Act confirming the same, as if the company were the actual holders of the said order and confirming Act, be accepted. This was seconded.—Mr. Kingsbury said he did not think the Vestry could comply with this, when they had for a long time been trying to put down overhead wires.—Mr. Wright said that the Vestry had objected to the Chelsea Electric Supply Company putting up overhead wires, and he did think the Vestry should object to this company putting up overhead wires. It was an impossibility to say that the wires would not break with the snow. He moved that the Vestry do not consent to the overhead wires.—Mr. H. Young said by the decision of the law courts the parochial authorities had not much to do with this question. The Cadogan Company were the same company, he believed, as the Grosvenor Company. The houses built by Messrs. Trollope were fitted with wires, and those gentlemen were connected with this company.—Mr. Mossop said the Cadogan Company wished to place themselves in the same position as the company that had an order, and in that order there was a clause which prevented overhead wires. He thought it was folly for two people to go to one district and compete when there were other parts of Chelsea that were open; but that was nothing to do with the Vestry.—The chairman, in answer to Mr. Wright, said he believed this company asked to be allowed to put themselves under the same terms as if they had been through the form of getting a provisional order.—The amendment was put and lost, and the motion carried.—The committee recommended, with regard to the letter received from the Chelsea Electricity Supply Company, that the Vestry should inform the company that this Vestry will assent to the Board of Trade using its powers under Section 70 of the Provisional Order to suspend the obligations of the company in all streets in Schedule A, save in the following:—Pont-street, Hans-place, Lennox-gardens, Lennox-gardens Mews, Clabon Mews, Cadogan-square, Cadogan-street, Draycott-street, and Draycott-place, for such term of years as they see fit.—Mr. Mossop moved the adoption of the report. This was to allow the company to reduce its area.—Mr. Moon seconded the motion, which was agreed to.

LAUNCH OF AN ELECTRIC YACHT.—The electric yacht, "The Countess," which has been built by Messrs. Lester and Perkins, at the Royal Albert Docks, to the order of the Electric Locomotive and Power Company, was launched on Saturday afternoon last. The boat has been constructed from the designs of Mr. Lester, and is 90ft. in length, 11ft. 6in. in the

Digitized by Google

beam, and 5ft. 6in. deep, and will draw about 3ft. of water. The motive power will be supplied by Elieson storage cells, and the screw will be driven by an Elieson motor of the pattern which has already been employed with some success for tramcar traction. The ceremony of christening was performed by the Countess of Galloway as the vessel hung suspended from one of the dock company's huge and powerful derricks. The boat was then swung bodily over the basin, and lowered into the water. The company afterwards adjourned to the workshop, where a light repast had been provided. Mr. T. Wickham proposed "The health of the Countess of Galloway," and spoke of the honour which her ladyship had done them by coming amongst them that day to perform the ceremony of christening the new boat. He felt that that was a ceremony full of promise and fraught with great advantage, not only to themselves, but to the community at large. The vessel they had seen launched that day would combine in itself two very important inventions which their company thought would some day make a very great sensation in the world. In that vessel there would be their new electric motor applying electricity in a new form, and their own accumulator or storage battery, to which they attached very great importance indeed. Therefore in thanking her ladyship for the act she had performed that afternoon, they felt that she had launched and put before the world a scheme which was fraught with great consequences in the future. They felt and hoped that the day was not far distant when not one of Her Majesty's ships or the vessels of the great navigation companies would go to sea without a launch of that kind. In returning thanks on behalf of the Countess, the Earl of Galloway said that had her ladyship not been confident of the success of the scheme they had in hand, he was certain she could not have been persuaded to assist in its development. He also took great interest in the proceedings of the Electric Locomotive and Power Company, but he did not think that vessel would have been built had it not been for the suggestion of Mr. Lester, who was one of the most active of their directors, and who by means of his firm had been instrumental in its construction. Other toasts followed.

Proposed Electric Lighting in Cork.—A special meeting of the Standing Committee of the Cork Corporation was held on Monday week to consider the representations and estimates of Mr. D. O. Bate, of the firm of Messrs. Laing, Wharton and Down, electrical engineers, London, respecting the Thomson-Houston system of electric lighting, with a view of ascertaining if the employment of such a system was practicable and less expensive than the present system of lighting the city by gas. Mr. Bate was called before the committee, and said that since the council meeting had referred him to the committee he had called upon Mr. M'Mullen, the city engineer, who had furnished him with particulars, on which he was able to base somewhat of an estimate as to the number of electric lights required to replace a certain number of gas lights. Approximately, 1,300 lamp posts carried a little over 1,300 jets, and the cost of their maintenance was £4,883. As against that, the corporation could probably profitably utilise 100 arc lights in a number of the streets of the town, leaving the small and crooked streets, which could not be lighted successfully by electricity, to be lighted in the present way. Basing his calculation at £24 per arc, the arcs would cost £2,400 per annum. At the lowest estimate each of these lamps would take the place of six gas jets. That would leave 700 gas jets in the small streets, which would cost, at the same rate, £2,629, and that, added to £2,400, made £5,030, as against £4,883 by the present system of lighting. That was an excess of £147. But in some places he could extinguish ten jets for one electric light, and, making allowance for this additional saving, he found the cost of lighting to be £4,654, £229 less than the cost at present. His esitmates were based on the figures for the year 1885. The city was illuminated by gas, at an average of nine hours per night; and he reckoned for keeping the electric lamps alight for ten hours, the same as his firm usually reckoned for English towns. If the corporation would use oil in the smaller streets, like the Waterford people, they would gain £700 a year. The Lighting Committee of Waterford had accepted the tender of his firm to light the streets of that city for the next five years, and this was now awaiting confirmation by the council. After some discussion it was finally resolved "that Mr. Bate and the engineer select within the channels the sites for 100 electric lamps, Mr. Bate then to furnish an estimate for supplying and maintaining such 100 lights for three or five years; the engineer to ascertain exactly what number of the present gas lamps might be extinguished if those 100 electric lights were erected."—*Gas World.*

Galvanometer Deflection by Alternating Currents.—The interesting and important discovery connected with alternating currents, made by Dr. Fleming in this country (and re-discovered apparently a little later by Prof. Elihu Thomson in America) renders it also interesting to note what was previously known with regard to the use of the galvanometer, with alternating currents. In Dr. Fleming's galvanometer (see *The Electrician*, May 6th) it will be remembered that the suspended needle takes the form of a thin copper disc, and the force by which it is deflected is due to the couple established between the alternating field of the coils and the Foucault currents in the disc, the latter being subject to a retardation due to the time constant of the disc, which has the effect of disturbing the equilibrium between the magnetic effect of the reversals. The fact that a *magnetised* needle is, under certain conditions, deflected in an alternating field was, however, observed by Poggendorff at least as early as the year 1838 (*Pogg. Ann.*, Vol. XIV., p. 353). The phenomenon was named by Poggendorff "Doppelsinnige Ablenkung." Thirty years later, at the meeting of the British Association at Norwich, a paper was read by the Hon. J. W. Strutt (Lord Rayleigh) "On a Permanent Deflection of the Galvanometer Needle by a Rapid Series of Equal and Opposite Induced Currents." This paper was not, however, printed in the *Transactions* of the Association, where the title alone appears. The next mention of the subject which we have been able to find occurs in 1876, when Mr. Chrystal contributed to the December number of the *Phil. Mag.* a paper entitled "Bi- and Uni-Lateral Galvanometer Deflection"; where (following Poggendorff) bi-lateral deflection refers to the deflection of a magnetised needle by alternating currents, which, under certain conditions, may be directed indifferently to either side of zero according to the accident of the first impulse, actual zero being in fact a position of unstable equilibrium. Mr. Chrystal made, however, the discovery that a different effect comes into play when the permanent field in which the needle moves is very strong compared with the alternating field, due to the current in the coils. In this case the equilibrium of the needle while at zero is much more nearly stable than in the previous case; if, however, before the current is started, the needle be moved into any position, either to the right or left of zero, then, on starting the current, it remains deflected upon that side of the scale. Mr. Chrystal enters into a mathematical explanation by which both effects are accounted for. It is, however, clear from what we now know that, owing to the Foucault current effect, the complete theory of the deflection of a magnetised needle must be very complex.

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 519, Vol. XVIII.)

ERRATA.—On page 479, Vol. XVIII., the two last lines of the chapter should read as follows:—

The output $\propto \mu \times$ angular velocity $\times$ (linear dimensions) $^{\frac{7}{2}}$

or output $\propto \mu \times$ peripheral velocity $\times$ (linear dimensions) $^{\frac{5}{2}}$

Given the quality of iron we have now the necessary data from which to calculate the value of ρ,

for $$\zeta = Z_2 - Z_1 = \frac{p_1}{\rho};$$

thus $$\rho = \frac{p_1}{Z_2 - Z_1} = \frac{v}{\text{diameter of armature}},$$

v being constant for all sizes of the same type.

After the above value is thoroughly well determined by experiments made with a number of machines, the estimated maximum E.M.F. will afford a means of gauging the comparative magnetic quality of the iron, in which, by bringing this or some equally good test to bear, we may hope in time to get a more strict uniformity.

Returning to our design, we have now to fix upon the cross section of the field-magnets. Knowing the value of Z_2 (making $\sigma_2 = \sigma_1$) we have

$$AB = \frac{Z_2}{18\sigma_2}.$$

In dealing with the length of the cores, we must adopt a similar treatment to that which was employed for the dimensions of the armature, viz., a balance must be struck between the heating effect and the radiating surface.

At first sight this may seem a little difficult, because the conditions are not quite the same as in the armature, where conduction of the heat to other parts of the machine was negligible. A little reflection will, however, show that the ratio between the amounts of heat dissipated respectively from the surface of the magnet bobbin itself and from other surfaces on the frame, &c., is constant for machines of any one type. Thus, having found a coefficient giving good practical results in one case, we may be sure that it will serve for all sizes, having the same general configuration. A point of considerable practical importance arises from the above considerations, and although implicitly contained in the treatment, it will bear emphasis, viz., that the density of current in both armature and magnet winding must necessarily be diminished as the linear dimensions are increased.

For suppose the winding to consist of a single turn of solid copper, the resistance would then be inversely proportional to the linear dimensions, which we will denote by L. Thus $r \propto \frac{1}{L}$. The energy in watts absorbed in this resistance is $w \propto \frac{C^2}{L}$, and by the conditions $\frac{C^2}{L} \propto L^2$ thus $C \propto L^{\frac{3}{2}}$; but if the density were to remain constant C would vary with L^2.

Since in practice magnets have to be wound with wires of various sections in which the coefficient of insulation assumes different values, care must be taken to allow sufficient space for the smallest sizes which are likely to be used. Of course the proposition that the core surface may be used as the basis of calculation for the number of watts converted into heat in any one bobbin only holds good if the ratio between the core radius and the radius to the outside of the winding is kept constant for all sizes. This ratio, we have seen, is subject to modifications in a given size when wound for different purposes, but a constant *average* ratio may very well be maintained. It is now necessary to fix both this average ratio and also a ratio between the heat dissipated and the core surface. For the first, a good proportion will be to make the average depth of winding one-half the core radius, or, if rectangular in section, one-fourth the short diameter. For the second, a maximum of one watt per square inch of core surface will be found a fairly safe rule in general practice. We now have P the exciting power, A B the core section (from which we can also obtain the depth of winding), and a certain ratio in any given case between the length of core and the work done thereon—that is, a given number of watts per linear inch. This gives the sectional area of the wire for series winding, for then the current C flowing in each bobbin is known, and writing d for the depth of winding, w for the watts per linear inch, l for the length of a mean convolution, and A for the copper section, we have

$$\frac{d\,l\,\mu^2}{162 \times 10^4 \,.\, A^2} = \text{resistance} = \frac{w}{C^2},$$

from which A is found. The number of windings n per unit length follow immediately from this equation, and $\frac{P}{2Cn}$ then gives the length of core, the numeric being inserted because there are in general two cores to each magnet.

The length of the iron portions of the magnetic circuit are now known and have been determined in such a way as to secure for them a minimum value; the length of the air gap, δ, has, however, so far only been fixed in a purely arbitrary manner, and we must try to deal with this quantity a little more fully.

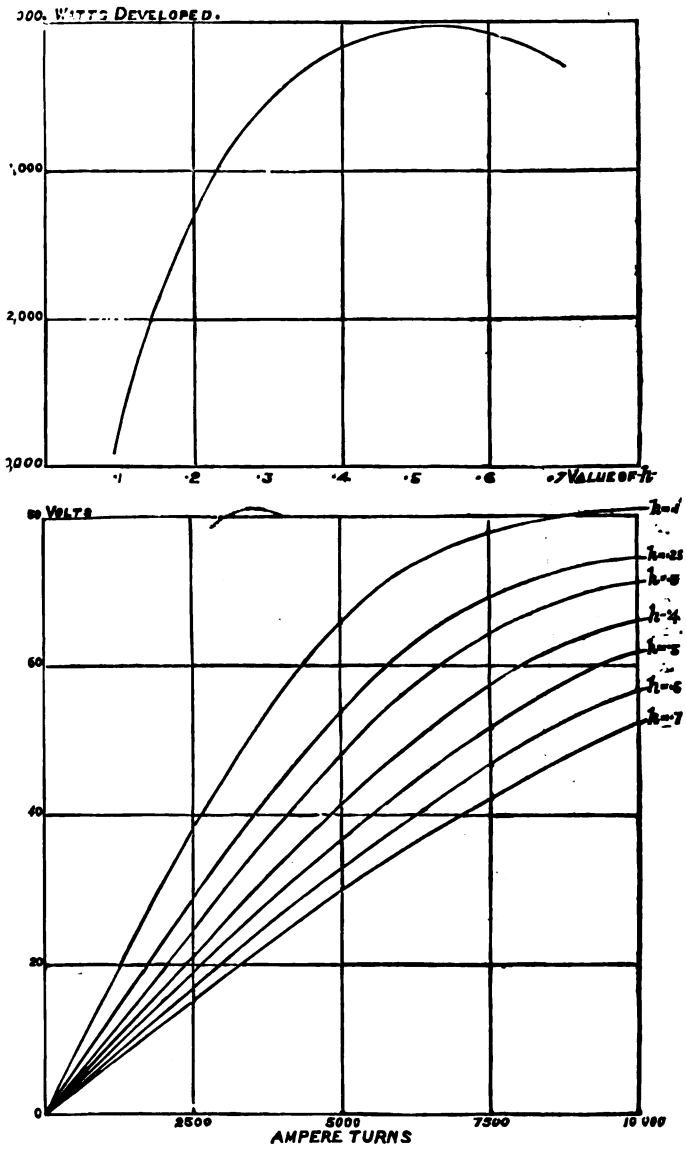

FIG. 9.

It consists of two parts, viz., the depth of winding, which we will call h, and the clearance Q necessary to mechanical safety. What we have now to do is to express the output as a function of h, in order that the effect of modifications in this latter quantity may be traced. As our object is to secure the

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 519, Vol. XVIII.)

ERRATA.—On page 479, Vol. XVIII., the two last lines of the chapter should read as follows:—

The output $\propto \mu \times$ angular velocity $\times$ (linear dimensions) $^{\frac{7}{2}}$

or output $\propto \mu \times$ peripheral velocity $\times$ (linear dimensions) $^{\frac{5}{2}}$

Given the quality of iron we have now the necessary data from which to calculate the value of ρ,

for $$\zeta = Z_2 - Z_1 = \frac{p_1}{\rho};$$

thus $$\rho = \frac{p_1}{Z_2 - Z_1} = \frac{v}{\text{diameter of armature}},$$

v being constant for all sizes of the same type.

After the above value is thoroughly well determined by experiments made with a number of machines, the estimated maximum E.M.F. will afford a means of gauging the comparative magnetic quality of the iron, in which, by bringing this or some equally good test to bear, we may hope in time to get a more strict uniformity.

Returning to our design, we have now to fix upon the cross section of the field-magnets. Knowing the value of Z_2 (making $\sigma_2 = \sigma_1$) we have

$$AB = \frac{Z_2}{18\sigma_2}.$$

In dealing with the length of the cores, we must adopt a similar treatment to that which was employed for the dimensions of the armature, viz., a balance must be struck between the heating effect and the radiating surface.

At first sight this may seem a little difficult, because the conditions are not quite the same as in the armature, where conduction of the heat to other parts of the machine was negligible. A little reflection will, however, show that the ratio between the amounts of heat dissipated respectively from the surface of the magnet bobbin itself and from other surfaces on the frame, &c., is constant for machines of any one type. Thus, having found a coefficient giving good practical results in one case, we may be sure that it will serve for all sizes, having the same general configuration. A point of considerable practical importance arises from the above considerations, and although implicitly contained in the treatment, it will bear emphasis, viz., that the density of current in both armature and magnet winding must necessarily be diminished as the linear dimensions are increased.

For suppose the winding to consist of a single turn of solid copper, the resistance would then be inversely proportional to the linear dimensions, which we will denote by L. Thus $r \propto \frac{1}{L}$. The energy in watts absorbed in this resistance is $w \propto \frac{C^2}{L}$, and by the conditions $\frac{C^2}{L} \propto L^2$ thus $C \propto L^{\frac{3}{2}}$; but if the density were to remain constant C would vary with L^2.

Since in practice magnets have to be wound with wires of various sections in which the coefficient of insulation assumes different values, care must be taken to allow sufficient space for the smallest sizes which are likely to be used. Of course the proposition that the core surface may be used as the basis of calculation for the number of watts converted into heat in any one bobbin only holds good if the ratio between the core radius and the radius to the outside of the winding is kept constant for all sizes. This ratio, we have seen, is subject to modifications in a given size when wound for different purposes, but a constant *average* ratio may very well be maintained. It is now necessary to fix both this average ratio and also a ratio between the heat dissipated and the core surface. For the first, a good proportion will be to make the average depth of winding one-half the core radius, or, if rectangular in section, one-fourth the short diameter. For the second, a maximum of one watt per square inch of core surface will be found a fairly safe rule in general practice. We now have P the exciting power, A B the core section (from which we can also obtain the depth of winding), and a certain ratio in any given case between the length of core and the work done thereon—that is, a given number of watts per linear inch. This gives the sectional area of the wire for series winding, for then the current C flowing in each bobbin is known, and writing d for the depth of winding, w for the watts per linear inch, l for the length of a mean convolution, and A for the copper section, we have

$$\frac{d\,l\,\mu^2}{162 \times 10^4 \cdot A^2} = \text{resistance} = \frac{w}{C^2},$$

from which A is found. The number of windings n per unit length follow immediately from this equation, and $\frac{P}{2Cn}$ then gives the length of core, the numeric being inserted because there are in general two cores to each magnet.

The length of the iron portions of the magnetic circuit are now known and have been determined in such a way as to secure for them a minimum value; the length of the air gap, δ, has, however, so far only been fixed in a purely arbitrary manner, and we must try to deal with this quantity a little more fully.

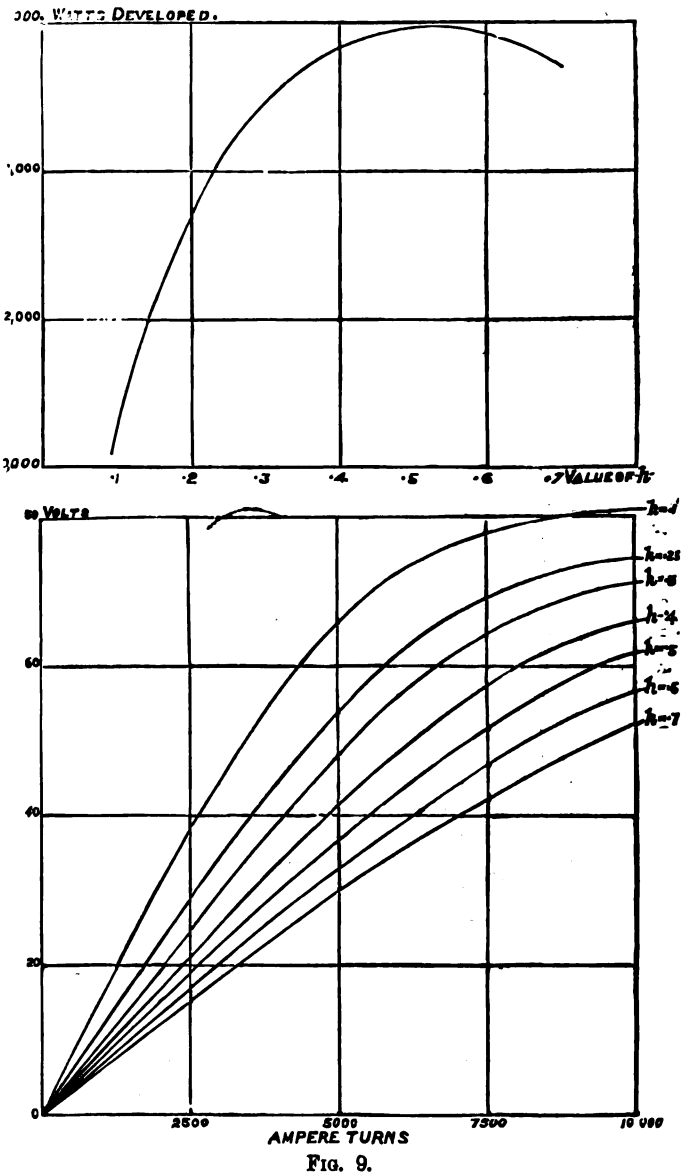

FIG. 9.

It consists of two parts, viz., the depth of winding, which we will call h, and the clearance Q necessary to mechanical safety. What we have now to do is to express the output as a function of h, in order that the effect of modifications in this latter quantity may be traced. As our object is to secure the

Digitized by Google

highest efficiency as well as the greatest output, we will cause the two quantities to vary in the same direction by keeping the work done in the armature constant. We then have from equation (2).

$$r_a = \frac{t(a+2\beta)}{\beta(b-\beta)},$$

where $$t = \frac{N^2}{162\times10^4 . \pi\mu^2 P^2 R},$$

$$a = q+p \text{ and } b = 1-p;$$

thus $$r_a = \frac{t\left(a+\frac{2h}{R}\right)}{\frac{h}{R}\left(b-\frac{h}{R}\right)}.$$

Also $C = \sqrt{\frac{W}{r_a}}$ where W = watts in armature. We then have

$$C = \left\{\frac{\frac{Wh}{R}\left(b-\frac{h}{R}\right)}{t\left(a+\frac{2h}{R}\right)}\right\}^{\frac{1}{2}}$$

The electromotive force E can also, as we have seen, be expressed in terms of Z, the number of lines passing through the armature core. In this expression Z is a function of h, but as there is also a saturation term, k, which is affected by modifications in h, a general solution of the problem presents serious difficulties. We can, however, take a particular case, and calculate from the tangent formula already given a number of curves of E.M.F. corresponding respectively to certain values of h; a vertical line can then be struck at any suitable exciting value along the line O X, and the points of intersection with the curves will give the E.M.F. in each case. These values will then be taken to form products with the corresponding values of C, and thus another curve of the products of E C may be made in which the various values of h are taken along the line O X. Although such a curve is limited in its actual application to one particular machine, it may yet be taken as *characteristic* of all machines. A case is therefore worked out in Fig. 9 in which the constants are as follows:—

W = 600.
R = 7·625.
t = ·000336.
a = ·8.
b = ·6.
N (number of turns on armature) = 320.
n (revolutions per minute) = 900.
R_A = 1·22.
R_F = 2·85.
ρ (resistance of air leak) = 80.

SIR WILLIAM THOMSON'S NEW ELECTRIC MEASURING INSTRUMENTS.

Standard Electric Balances.

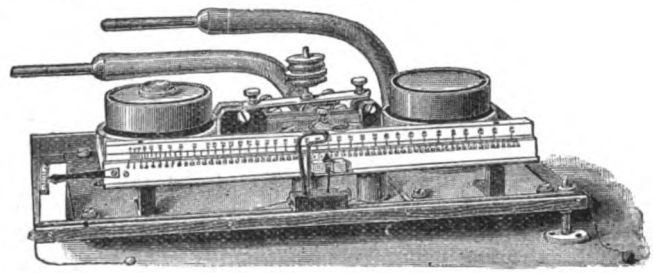
1. These instruments are founded on the mutual forces, discovered by Ampère, between movable and fixed portions of an electric circuit. The shape chosen for the mutually-influencing portions is circular, and each such part will be called for brevity an ampere ring, or sometimes simply a ring, whether it consists of only one turn or of any number of turns of the conductor.

2. In the balance instruments each movable ring is actuated by two fixed rings—all three approximately horizontal. In each of the balance instruments there are two such groups of three rings—two movable rings attached to the two ends of a horizontal balance arm pulled, one of them up and the other down, by a pair of fixed rings in its neighbourhood. The current is in opposite directions through the two movable rings to practically annul disturbance due to horizontal components of terrestrial or local magnetic forces. In the direct reading voltmeter there is only one fixed ring acting on a single movable ring, which is attached to one end of the balance arm and counterpoised by a weight at the other end.

3. In all the instruments the balance arm is supported by two trunnions, each hung by an elastic ligament of fine wire, through which the current passes into and out of the circuit of the movable rings or ring.

4. In the balance instruments the mid-range position of each movable ring is in the horizontal plane midway or nearly midway between the two fixed rings which act on it. The current goes in opposite directions through the two fixed rings, so that the movable ring is attracted by one of the fixed rings and repelled by the other.

5. In the balances to measure direct currents of from 5 amperes to 1,000 amperes the outer diameter of each pair of fixed rings is somewhat smaller than the inner diameter of the movable ring, and the proportions are so arranged that the force experienced by the movable ring is very nearly constant through half a centimetre on each side of its middle position This is the sighted position for the ordinary use of the balance; and it is marked by the zero line or middle one of five stout black lines across the scale traversed by the pointer of the balance.



Standard Electric Balance.

6. In the balance instruments to measure alternate currents of all strengths, and direct currents of from 5 milliamperes to 10 amperes the fixed rings are larger than in the instruments to measure the larger direct currents. Their outer diameters are greater and their inner diameters less than that of the movable ring which moves between them, above one and below the other. The position of the movable ring equidistant from the two fixed ones is a position of minimum force, and the sighted position, for the sake of stability, is above it at one end of the beam and below it at the other, in each case being nearer to the repelling than to the attracting ring by such an amount as to give about $\frac{2}{10}$ per cent. more than the minimum force.

7. In the balance instruments to measure alternating currents (which may be also used for direct currents) of from 5 amperes to 1,000 amperes the main current through each circle, whether of one turn or of more than one turn, is carried by a wire rope of which each component wire is insulated by silk covering, or otherwise from its neighbour, in order to prevent the inductive action from altering the distribution of the current across the transverse section of the conductor.

8. The balancing is performed by aid of a weight which slides on an approximately horizontal graduated arm attached to the balance; and there is a trough fixed on the right hand end of the balance, into which the proper counterpoise weight is placed, according to the particular one of the sliding weights in use at any time (§ 11 below). For the fine adjustment of the zero a small metal flag is provided (as in an ordinary chemical balance) actuated by a fork, with a handle below the case outside as shown in the drawing. To set the zero, the left hand weight is placed with its pointer at the zero of the scale, and the metal flag is turned to one side on the other until it is found that, with no current going through the rings, the balance rests in its sighted position.

Digitized by Google

9. To measure a current the left hand weight is slipped along the scale until the balance rests in its sighted position. The strength of the current is then read off approximately on the fixed white scale (called the inspectional scale) with aid of the finely divided scale, for more minute accuracy, according to the explanations given in § 13 below. Each number on the inspectional scale is twice the square root of the corresponding number on the scale of equal divisions.

10. The slipping of the weight into its proper position is performed by means of a self-releasing pendant hanging from a hook carried by a sliding platform, pulled in the two directions by two silk threads passing through holes to the outside of the enclosure.

11. Three pairs of weights (sliding and counterpoise) in the ratios of 1 : 4 : 16 or 1 : 4 : 25 are supplied with each instrument, adjusted so that each pair gives a round number of amperes, or half amperes or quarter amperes, or of decimal sub-divisions or multiples of these magnitudes of current, on the inspectional scale.

12. The useful range of each instrument is about from 1 to 25 of the smallest current for which its sensibility suffices. The ranges of the different types of this instrument regularly made are—

I.	Centi-ampere balance :	from 2 to 50	centi-amperes.
II.	Deci-ampere	„ „ 1 to 25	deci-amperes.
III.	Ampere	„ „ 1 to 25	amperes.
IV.	Deca-ampere	„ „ 4 to 100	„
V.	Hecto-ampere	„ „ 20 to 500	„

The following table shows for each type of instrument the value per division of the inspectional scale corresponding to each of the three pairs of weights :—

	I. Centi-amperes per division.	II. Centi-amperes per division.	III. Deci-amperes per division.	IV. Amperes per division.	V. Ampere per division.
1st Pair of Weights.	·25	1	1	·5	2·5
2nd „	·50	2	2	1·	5·0
3rd „	1·0	5	5	2·	10·0

13. The fixed inspectional scale shows approximately enough for many purposes the strength of the current; the notches in the top of the aluminium scale show the precise position of the weight corresponding to each of the numbered divisions on the white scale, and practically annul error of parallax due to the position of the eye. When the pointer is not exactly below one of the notches corresponding to integral divisions of the inspectional scale, the proportion of the space on each side, to the space between two divisions, may be estimated with considerable accuracy. Thus we may readily read off 34·2 or 34·7 by estimation with little chance of being wrong by one in the decimal place. But when the utmost accuracy is required the reading on the fine scale of equal divisions must be taken, and the strength of current estimated by aid of the table of doubled square roots appended to these instructions. Thus, for example, if the reading is 292 we find 34·18, or say 34·2 as the true scale reading for strength of current ; or, again, if the balancing position of the pointer be 301 on the fine scale we find 34·65 as the true reading of the inspectioual scale.

14. The centi-ampere balance, with a thermometer to test the temperature of its ampere rings, and with platinoid resistances up to 2,000 ohms, serves to measure potentials of from 10 volts to 200 volts.

Direct-Reading Vertical-Scale Voltmeter.

15. This instrument is commonly called "engine-room voltmeter," because it can be read at such a distance as across an engine room, and requires for taking a reading no balancing manipulation as in the balance ampere meters. It is convenient not only for engine rooms, but for use in any part of an electric light installation, or in houses supplied with electric light. It shows, by inspection, whether the potential is exactly the proper amount, or, if not exactly so, by what fraction of a per cent., or by what percentage, down to 10 per cent. below or up to 10 per cent. above, it differs from the proper amount.

16. The inspectional voltmeters consist of—

a. A fixed platinoid resistance, in circuit with a fixed and a movable ampere ring.

b. A V-trough rigidly fixed to the movable ring, and carrying the weight proper to the potential to be measured and the temperature of the instrument.

c. A thermometer to show the temperature of the ampere rings.

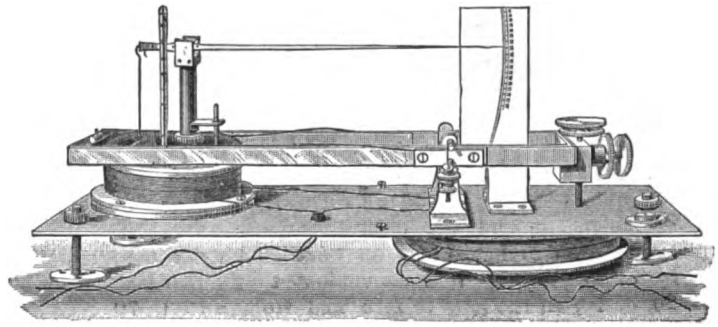
d. A lever, multiplying the motion of the movable ring, and showing the potential to be measured on a vertical graduated scale.

17. The fixed and movable ampere rings are each composed of many turns of fine insulated copper wire, with a total resistance of about 100 ohms. The amount of the added platinoid resistance depends on the potential to be measured in the ordinary use of the instrument. Thus, for example, for potentials of from 10 per cent. below to 10 per cent. above 100 volts, the platinoid resistance is 700 ohms; for potentials of from 10 per cent. below to 10 per cent. above 200 volts, the platinoid resistance is 1,500 ohms.

18. Temperature error is practically annulled in the use of the instrument by simply reading the thermometer (14 *b* and *c*), and seeing that the weight in the trough is the one corresponding to the temperature. Five weights, corresponding to temperatures centigrade of 15°, 20°, 25°, 30°, 35°, are supplied with the instrument in receptacles marked with the temperature, so that no mistake can be made in seeing that it is the right weight that is in use on the instrument at any time.

Marine Voltmeter.

19. The mass of the moving part of the balance voltmeter and engine room voltmeter is too great to be convenient for sea use, and instead a small oblate of soft iron supported on a stretched platinoid wire in the centre of a solenoid of fine copper wire, connected in series with platinoid resistances, variable according to the potential to be measured, serves for marine voltmeter. A pointer carried by the oblate shows, by inspection, direct reading of currents of from 90 to 120 milliamperes. When, as is most commonly the case, the mean potential to be measured is 100 volts, the platinoid resistance is adjusted to make up, along with the fine copper wire solenoid (of which the resistance is about 60 ohms), a total resistance of 1,000 ohms. Thus, the direct reading of potential on scale is in volts.



Engine Room Voltmeter.

20. This instrument is founded on the principle that an oblate spheroid of soft iron, movable round a diameter, tends to turn its equatorial plane parallel to the lines of force in a uniform magnetic field. In the zero position the equatorial plane of the oblate is inclined about 45° to the lines of force of the solenoid, and torsion by the upper and lower parts of the bearing platinoid wire tends to turn it into a position perpendicular to the lines of force. This tendency is balanced by a stop against the needle when no current, or any current not exceeding 90 milliamperes, passes through the solenoid. When a current exceeding 90 milliamperes passes, the torsion couple is balanced by the couple due to the electro-magnetic force.

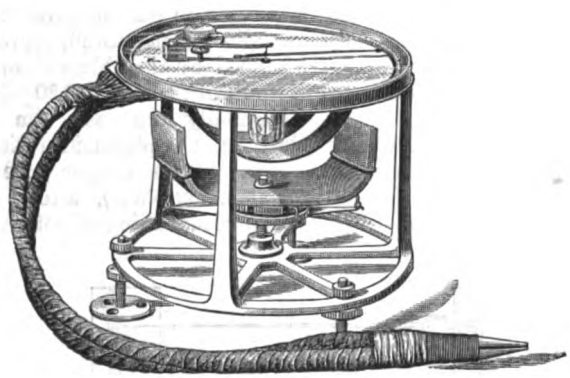
Adjustable Magneto-Static Current Meter.

21. This instrument has an advantage over the balance instruments, important for some practical purposes, of being available as an accurate direct-reading current meter through a continuous range of from 1 to 90 or 100. Its disadvantages are that it is not available as an alternate current instrument,

Digitized by Google

and that the magnetism of the steel directing-magnet does not remain absolutely constant. With good quality of steel, a proper preliminary *ageing* of the magnet (by heating it several times in boiling water and cooling it again, and subjecting it to somewhat varied rough usage) brings it to a condition in which its magnetism may probably remain exceedingly nearly constant month after month and year after year. Still, it can never be relied upon as absolutely constant. It is therefore necessary to have some means of accurately retesting and readjusting the instrument at any time. This is always easily done with the utmost accuracy if one of the balance ampere meters is available as a standard.

22. When the instrument is used as a lamp counter, primary adjustment or readjustment, at any time, can be performed with great ease, without the aid of any other measuring instrument, by turning the screw platform which bears the adjusting magnet, so as to raise it or lower it until it is found that the deviation from zero produced by the current of any number of lights shows a corresponding number on the scale of the instrument. After each motion of the magnet the zero of course must be readjusted, which can be done either by throwing off all the lamps, or throwing the instrument out of circuit, and then turning the magnet till the needle points to zero. The lower screw must be screwed firmly up to pinch the upper screw when the adjustment is completed. If this is done firmly enough the magnet may at any time, without scruple, be turned round on its platform and brought back again whether for setting the zero, or for any other purpose, as it is only by turning the upper screw that the distance of the magnet from the needle can be altered.



Magneto-Static Current Meter.

23. The scale has 100 divisions, corresponding to equal differences of tangents of the angle between the magnetic axis of the needle and the electro-magnetic axis-vertical of the rings. The divisions may be numbered from 0 to 100; but for many purposes it is convenient to number them from 30, 20, or 10, on the left, to zero, and from zero to 70, 80, or 90 on the right; because we thus have larger divisions in the neighbourhood of the zero than when it is taken at the extreme left of the scale, and because it is sometimes convenient to measure small currents in the direction opposite to that of the currents ordinarily measured. For most purposes probably the numbering 10 left to zero and zero to 90 right will be found most convenient. With scales so numbered any number of lamps from 1 to 90 can be counted by integral numbers of scale divisions. Of course this is not possible to any great accuracy, because the lamps are not all rigorously equal, but the lamp counter serves the important practical purpose of showing at any time the exact number of lamps in use when less than 10 or 15, and nearly enough for practical purposes the exact number however many there are. In private houses it is very useful as a check against some lamp or lamps being left accidentally alight in a cellar or safe-room or other place where the fact of its being alight might escape observation for days or weeks together.

24. To count larger numbers of lamps up to 1,000 or more the instrument is made with smaller rings of more massive conductor. The same proportionate accuracy is attained as with the 100-lamp counter.

Adjustable Resistances or Mho-ohm Drum.

25. This is a combination of platinoid* conductors fulfilling the double object of an ordinary box of resistance coils in series, and a mho box by which a set of conductors can be connected any two or more of them in parallel, so that their conductances† shall be added, instead of the resistances being added, as in the ordinary box of resistance coils.

26. The conductors are coiled anti-inductively,‡ on a drum of thick sheet copper to serve the purpose, not only of bearing them and forming the main support of the instrument, but also of conducting away with great freedom the heat that is generated in each coil through which the current is flowing at any time, and so equalising the temperature of the different coils. A copper sheath is fixed outside in metallic connection with copper partition rings which separate the different coils. This sheath serves the purpose of protecting the coils against damage, and of spreading out the heat generated in each coil over a wide surface freely exposed to the external air, and so greatly diminishing the rise of temperature due to currents through the coils. It is also convenient for the application of a water jacket for laboratory or other purposes in which special care as to the temperature of the coils is needed.

27. All the resistances on the drum are connected in series by permanent solderings. The varying connections for the use of the instrument are made by circular copper cams, mounted on vertical copper shafts, connected by solderings and flexible strands with the soldered joints between the coils in series on the drum. Each shaft is mounted so as to work in two positions, an upper and a lower.

28. For making the mho connections all the shafts are placed in the upper position, and the connections are made by turning the cams so as to press on the outer or inner of two concentric copper rings between which the shafts and cams are mounted.

29. For the ohm connections the shafts are let down to their lower position, and the connections are made by turning the cams so as to short-circuit whichever of the coils are not to be included in the sum of the resistances in series. The working of this part of the plan is precisely the same as in the ordinary resistance-box, except that the short-circuitings are made with easier manipulation by cams with single contacts, instead of by removable plugs with contacts on each side of each plug. This halving of the number of the non-soldered contacts is a serious advantage.

30. In order that the single set of resistances may be available both for the connection in series (for ohms) and for the connection in parallels (for mhos) their proportions must be according to powers of 2 as in ordinary weighing by subdivi-

* When the special purpose is the measurement of the conductivity of copper, the conductors of the mho-ohm drum are made of copper instead of platinoid.

† This is Oliver Heaviside's word.

‡ That is to say, each wire is doubled on itself with the two parts everywhere close together, but well insulated from one another.

Adding E to any combination of the other conductances adds $\frac{1}{2} \times \frac{1}{2048}$ of a Mho to the sum.

sion of the pound into halves, quarters, eighths, sixteenths (or ounces), and half and quarter ounces. Thus when the smallest single resistance on the drum is 1 ohm the other resistances are 2, 4, 8, 16, 32, 64, 128, 256, 512, 1,024, 2,048, and 4,096 ohms, this last being the highest single resistance on the drum as ordinarily made, but higher resistances may be added if desired.

31. The dual system, besides its availability for the two modes of connection, has this advantage, that with it a similar number of coils suffice than in any of the decimal systems of resistance coils ordinarily in use.

BELGIAN ELECTRIC LIGHTING REGULATIONS.

The following regulations for the construction of electric lighting circuits have been issued by the Belgian Postal and Telegraphic Administration :—

1. The lighting circuits shall be entirely metallic, without any earth connections whatever, and connections with water or gas pipes are strictly prohibited.

2. In the case of all portions situated upon State property, or in the neighbourhood of telegraphic or telephonic wires belonging to the State, the conducting wires, if not laid underground, shall be covered with materials which will ensure complete electric insulation, and the whole system must be made impermeable to water.

3. The cables shall be made of sufficient strength to resist any strains to which they may be exposed, and, if necessary, they shall be supported throughout their entire length by wires or metallic cables of the requisite strength, and they shall be placed at a sufficient height to allow the free passage under them of the highest vehicles, and especially of the fire escapes and ladders used for repairing the telegraph and telephone wires.

4. At their points of support on buildings, posts, buttresses, &c., the cables shall be attached in one uniform manner to porcelain insulators, and in such a way that the insulating covering may not be exposed to either mechanical or electrical deteriorations.

5. If bare wires be used for the continuation of cables carried over the places mentioned in Section 1, the bare wire shall not approach within a distance of two metres from any roof or building; it shall be furnished at the points of junction with double insulating covering for a distance of 60 centimeters at least from the supporting insulator, and the junction of the wire to the cable shall be perfectly soldered and insulated.

6. In any places where the direct and return conductors may be near together, or where a dangerous difference of potential may exist, especially in the neighbourhood of the central lighting station, the conductors shall be covered with an additional layer of insulating material; they shall be placed at a distance of not less than two metres from any roof or building, and their distance asunder shall be such as to preclude the possibility of any person touching both of them at the same time.

7. Wherever the lightning conductors cross telegraph or telephone wires, they shall pass underneath the latter at right angles, and at a minimum distance from them of 2 metres. The points of support of these cables shall be at a minimum distance of three metres on one side and the other of the telegraph and telephone wires. To prevent the wires, in the case of breakage, from coming in contact with the electric light conductors, the contractor shall place above each of the latter, along the whole length of the crossing, a metallic wire of sufficient strength

8. The electric lighting conductors and the telephone and telegraph wires shall, as far as possible, not be allowed to run parallel to one another. When this condition cannot be fulfilled the distance between them shall never be less than 12 metres.

9. In conformity with royal decree of the 15th of October, 1876, the contractor shall give to the telegraphic department the preliminary notice prescribed in Section 1 of this decree in the case of any work to be carried out in the neighbourhood of telegraph or telephone lines established or conceded by the Government.

10. The contractor must give a general undertaking to avail himself in his installations of every possible measure recognised by science or by experience as a safeguard.

The installation shall be maintained in the most perfect condition possible, and they shall be tested regularly at least once daily.

11. The contractor shall assume the entire responsibility for all damage or accident arising from his electric light installations.

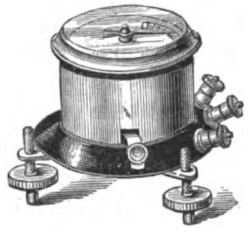
12. The present authorisation is merely permissive; it does not include the right of placing supports upon any buildings or lands belonging to the State, for which a separate authorisation must be obtained in each special case, and it may be revoked at six weeks' notice.

The State reserves to itself the right of making any changes in these regulations, of making new ones, and of demanding at any time that electric lighting conductors, situate on State property, or in the neighbourhood of telegraph or telephone lines established or conceded by the Government, be forthwith removed, without giving any indemnity to the contractor.

13. The installations carried out on State property, and in the neighbourhood of the aforesaid telegraph and telephone wires, may not be modified in the future without special permission from the Government.

NEW PORTABLE HORIZONTAL GALVANOMETER.

This galvanometer, which is illustrated below, has been designed more especially with a view for testing purposes. Its double bobbin is wound with two resistances as in an ordinary detector, and the needle which



swings inside the coils is fitted to a spindle carrying at its upper extremity an agate centre which rests lightly on a delicate needle point, a balanced aluminium pointer being fixed to the spindle just below the cap. By this arrangement a highly sensitive instrument is constituted, and one that is well adapted for testing line circuits, lightning conductor earths, &c. To prevent breakage of the needle point in transit a small lever is so fitted that upon being screwed down the spindle is lifted off its resting place. The scale is carefully engraved on a silvered dial protected by a thick plate glass cover. In using it is only necessary so to place the instrument in the magnetic meridian that the zero is towards the north, and to level it by means of the three levelling screws below the base. This galvanometer has been introduced and is manufactured by Messrs. King, Mendham and Co., of the Western Electrical Works, Bristol.

THE CANADIAN PACIFIC CABLE ROUTE.

The day when wars and rumours of wars will be things of the past has not come yet, nor is that happy time likely to be known by the present generation. Many of our actions, individual and public, are dictated by the fear of what may be, and are not the result of calm reasoning. The proposed Pacific cable is one of those suggestions, and an attempt is being made to frighten the public into the support of a scheme which has few intrinsic merits to justify its claims to attention or support.

The proposed cable is either a business scheme or purely a political scheme. If the latter, the public must consider the matter as taxpayers; if the former, they must consider it as investors. The promoters seem to have an idea that it is partly a commercial and partly a political question, and that from the latter point of view the Government is to pay a subsidy as a guarantee to the investors against loss. It is singular that no ideas of this character were mooted before the building of the Canadian Pacific Railway. The letter of Mr. FINCH HATTON, given in another column, considerably clears the ground, and almost for the first time gives the real reasons why a Pacific cable is being promoted. The development of Canada is a praiseworthy object, against which we have not the faintest objection. The moral, however, of Mr. FINCH HATTON'S letter is that "Civilisation is a failure" and the "Caucasian is played out." The end of all things is to be war. Our industries are to be developed, not as peaceful industries, but as subsidiary aids in the event of war. No doubt in England we are wrong in imagining that if lines of steamers are wanted in the Pacific, lines of steamers will be provided by some of the long-headed business men who are always on the look out for means of profitably employing their capital. It might have been thought, also, that the Canadian Pacific Railway was promoted by business men for business purposes, and not from any transcendental idea of immediately directing the commerce of Australasia by a new route. We venture to deny that the transshipment and transport of goods across the American Continent will find favour in the eyes of shippers. If the Canadian Pacific Railway is to pay, it will be from the development of the country through which it runs, and for which it provides transport.

It is not so very long since a greater than Mr. FINCH HATTON argued that Canada must ultimately, and that ere long, become an integral part of the United States; and it may be asked whether this consummation of American politics is beyond the range of probabilities? If not, would not England be pickling a rod for her own back by subsidising the proposed scheme? Of course, the answer to this is emphatic, that there is no probability of such an event happening, and this answer would come from the very people who act as if the next war of England must of necessity be with a certain other nation and its allies. They claim infallibility in one direction, and no one must doubt the correctness of the views they express, otherwise it might again be objected that *viâ* Egypt was not the only route to the East, and that England has at least two other routes, and could, in a very short time, if necessary, provide a fourth, *viâ* the West of Africa, at a much less expense than by the Pacific.

We have no objection to a Pacific cable if it can be shown that it would pay as a commercial speculation, but we have a great objection to see the English taxpayers asked to contribute to a scheme which cannot pay of itself, and which is promoted solely in the hope of business from it assisting the Canadian Pacific Railway to become a paying concern. The new business opened up by the proposed cable would hardly pay for a repairing ship, and its traffic would mostly consist of traffic diverted from existing cables. In a few words the result of laying a Pacific cable would be largely and needlessly to increase the total capital invested in such means of communication to the districts under discussion—viz, the Australasian Colonies. Income would be taken from existing lines, and thus investors would lose on the one hand without gaining on the other, for it is not and cannot be contended that sufficient business would arise to give a fair return, say of five per cent., upon the total capital invested.

Before touching upon an argument which the promoters of the Pacific scheme have most unaccountably overlooked, it will be well to consider the value of one or two statements in the fourth paragraph of Mr. FINCH HATTON'S letter. He says that, "Of all lines that could possibly be laid it would be most free from any likelihood of interruption, either from natural causes or from the action of a hostile Power." Here is still seen the dominant idea that only Russia or France, and never can the United States be "a hostile power;" but the unforeseen is often that which happens, and what about likelihood of interruption if the States should be hostile? With regard to natural interruptions we can be more positive, and say emphatically that the Pacific Ocean is just as favourable or unfavourable as any other ocean. How does Mr. FINCH HATTON know that the bottom of the Pacific is the most "favourable one possible for prolonging the life of a cable," and how can he speak of great depth as being a protection? We remember the late Dr. SIEMENS advocated the deep, deep sea for safety of cables, but those who have had greater experience say that an unlevel bottom anywhere is dangerous, and the uncertainty and the cost of repairs increases greatly with the depth. From a business point of view deeply laid cables are a delusion and a snare, the bottom of the sea being as diversified as the surface of the land; and while we may think that the bottom of the Pacific is generally a level, it is

Digitized by Google

impossible to believe that a cable can be laid the distance proposed without passing over a number of bad places. These natural difficulties, however, are such as cables have daily to encounter, and we desire only to say that the Pacific presents features no better and no worse than are constantly met with; therefore it presents no special feature to cause it to be preferable to any other route.

With regard to tariffs it may be taken for granted that if the Government sees fit to subsidise the proposed line it will deal completely with the whole question.

It has, we think, been overlooked that the arguments put forward by the promoters of the Pacific cable scheme apply to every other cable. Why should the Pacific cable be subsidised as an alternate route, and the Atlantic cables be left to fight their competitors without State aid? Surely the Atlantic cables are as necessary in the chain as the further link. If the Government is practically to be responsible for the dividend of the new scheme, surely the Government, if the cable is so essential, can borrow the money with less difficulty, at a less cost, and carry out the work themselves. The argument as to the importance of the cable system for imperial purposes leads to the inevitable conclusion that if it is so supremely important the Government should, as in the case of the inland telegraph system, take it over and work it apart from all commercial questions. The fallacy of this conclusion is at once seen, inasmuch as such action would necessitate every Government having its own cable system. It might also be asked whether the subsidisation of a Pacific cable would not rather tend to develop trade in America than with England, and, if so, why should the English taxpayer be asked to support an alternative route to his own commercial disadvantage? A number of other pertinent questions might be asked, but surely enough has been said to show that cables ought to extend more as trade develops new demands, rather than to supply routes which have the sole merit of being alternative. Were it possible to form an international tribunal, the whole cable system would be best worked as an international and unpolitical monopoly. Links here and there in the hands of different companies do not form the best means to get the best results, and were the Pacific cable laid, it would only be one link in the chain, and absolutely at the mercy of some other link.

CORRESPONDENCE.

TELEGRAPH TARIFFS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of 13th inst. you publish the final proposals submitted by Mr. John Pender, the chairman of the Eastern Extension Telegraph Company, to the recent Colonial Conference. I trust that the proposal of the Pacific Telegraph Company, which was also submitted to the Colonial Conference, and which I herewith subjoin, may prove equally interesting to your readers. I have no wish to trespass upon your valuable space by criticising Mr. Pender's proposal and the figures which it contains, for nothing that can be urged in favour of or against the existing system of cables to Australasia and the East has any bearing whatever upon the transcendant importance of establishing telegraphic communication *vid* the Pacific.

If the existing lines of the Eastern Telegraph and Eastern Extension Companies were triplicated throughout it would still leave our communications with the East in their present extremely unsatisfactory state, for there are points of weakness in the Eastern system—such as the transit through Egypt—which nothing could ever render secure. They must inevitably be destroyed in time of war, and in such places ten lines of cables, if they existed, would be just as easy to cut as one.

Everything points to the fact that in the event of war England's military route to the East must be *vid* the Canadian Pacific Railway. It is equally certain that the progress of civilisation will shortly open up the Pacific Ocean as one of the main waterways of the world in time of peace. In order to justify her enormous expenditure on the Canadian Pacific Railway, Canada must extend her communications beyond the terminus at Esquimalt by means of ocean steamers to China, Japan, and Australasia. These liners, while employed as traders and mail carriers in time of peace, could be relied on for transport of troops on the outbreak of war. But without telegraphic communication, of course, it would be impossible to open up the Pacific, either as a highway for commerce or as a military route.

By laying a line of cable as is proposed from Canada to Australia, an alternative means of communication with the East would be established possessing advantages such as no other line could possibly offer. Of all lines that could possibly be laid it would be the most free from any likelihood of interruption, either from natural causes or from the action of a hostile Power. The bottom of the Pacific Ocean is the most favourable one possible for prolonging the life of a cable, while the great depth at which the cable would be laid would be equally efficacious in protecting it, both from the injurious effects of submarine insects and currents, and from the attempts of an enemy's cruisers to cut it.

In conclusion, I would call your readers' attention to the fact that the first proposal to reduce the tariff to Australasia to 4s. per word came from the Pacific Telegraph Company. Further than this, while 4s. a word is fixed as a minimum rate by Mr. John Pender, it is the maximum rate of the Pacific Telegraph Company. Should the estimates of increased traffic be in any way realised, the company will be in a position to effect still further very considerable reductions.—Yours, &c.,

HAROLD FINCH HATTON, Secretary.

Pacific Telegraph Company (Limited),
34, Clements-lane, E.C., 16th May, 1887.

Proposition of the Pacific Telegraph Company (Limited) to the Governments of Great Britain, Canada, and the Australasian Colonies.

1. The Pacific Telegraph Company shall lay a line of cable from Vancouver Island to Australia, touching at Hawaii, Fanning Island, Samoa, Fiji, and New Zealand.

2. The Governments of Great Britain, of Canada, and of the Australasian Colonies shall guarantee to the Pacific Telegraph Company Government traffic to the amount of seventy-five thousand pounds (£75,000) per annum, in such proportions as may be mutually agreed upon by the said Governments.

3. The above guarantee shall date from the completion of telegraphic communication between Canada and Australasia by the company, and shall continue in force for twenty-five years from that date, subject to the following conditions:—

4. In the event of telegraphic communication being interrupted thirty-five days shall be allowed to the company for repairs. If at the expiration of thirty-five days telegraphic communication shall continue to be interrupted, then the guarantee shall be suspended from that date until telegraphic communication be re-established.

5. The rate per word payable by the Governments shall be the current rate charged by the company to the general public, but such rate shall never exceed four shillings per word for the transmission of messages from England to Australasia.

THEORY OF SECONDARY CELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to Mr. Sprague, as far as I understand him, he thinks that electro chemists should not write thermochemical equation in the same way as other chemists, and accuses me of mixing things up because I use symbols in the same sense as nearly all modern chemists. The relation of calories and volts is perfectly understood by both Mr. Fitz-Gerald and myself, and we are in perfect accord as to facts on this point, and we only differ in notation.

Mr. Sprague says I set myself against facts; but he does not say what facts. From the extract quoted by him, it would appear that he thinks that I am wrong either in saying that

Digitized by Google

the E.M.F. of cells cannot be measured by the heats of combination, or that the heats of combination are not measures of chemical affinity. But he does not support his assertion.

Mr. Sprague seems to think discrepancies are partly due to the neglect of the heats of solution, &c.; but I at least have been careful not to forget these. He also thinks "the value depends upon the relative values of the volt, ohm, and ampere," and asks, "Will any electrician be good enough to tell us what those units mean? What is their value? and what is the true mechanical equivalent of a 'volt-ampere-ohm-second?'" I am sorry I cannot tell him what a "volt-ampere-ohm-second" is, or what its "dimensions" are, but perhaps that is because I am a chemist.

No one has striven harder than I against the introduction of the "legal" ohm; but Mr. Sprague is wrong in saying it is related to nothing but the erroneously fixed length of a column of mercury, which no one ever made or will make. It is one of the "true units," the decimal multiples of the absolute units for which Mr. Sprague's heart yearns, and that is the reason why it has been brought forward.

Finally, Mr. Sprague goes on to say that "in the present uncertainty of what the various electrical units mean," he reckons one volt = 23,287·7 calories, which, of course, is inaccurate, in spite of the decimal, and says that we should reduce the calories of actions to the equivalent in grammes. I can only repeat that electro-chemists are only a small portion of the community, and that you cannot expect chemists to alter their notation to suit us. In the meantime, H_2O stands for 18 grams of water, and however much we might like to call it 9 grams, we are not at liberty to do so.

Mr. Williams thinks the heats of solution, or of change of physical state, cause the discrepancies between the chemical affinities and the observed heats of combination; but this is not the case. As a striking example the case of salt and snow may be taken. The intense cold is, no doubt, produced by the change in the physical state of the water; but the affinity of salt for water is not nearly enough to account for the phenomenon. If the result were controlled entirely by the chemical affinities, however small, of course the least affinity of salt for water might force the snow to melt; but in other chemical actions the physical states have great influence. For instance, reactions in solutions generally take place so that solid precipitates can be formed.

That such questions as the heats of solutions come in in cells is shown by the higher electromotive force given when strong sulphuric acid is used—that is to say, when the acid has not to be torn away from its water.

As to the last part of Mr. Williams's letter, I think we are very nearly of the same opinion. I do not regard one part of the reaction as being primary and another as a side influence, but look upon them as of equal importance. Mr. Williams and I seem to be practically of the same mind, so the point is perhaps hardly worth discussing. His apt illustration as to lifting the weight seems a very good way of putting such cases.—Yours, &c, JAS. SWINBURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly correct an error in my letter last week. The reference to Dr. Ferguson's "Electricity" was printed as from an edition in 1886. I wrote, or meant to write, "edition 1866," and wished to show, by thus citing a little volume on my shelves, that the conception of an "electrolytic thread" was old as well as new.—Yours, &c.,

37, Burlington-road, W. E. ALDRED WILLIAMS.

THE CONSTRUCTION OF DYNAMOS.

TO THF EDITOR OF THE ELECTRICIAN.

SIR: I have been reading Mr. Fricker's articles with very great interest, and if you would oblige me by replying to the following questions I should be grateful. I have been designing a dynamo for fifteen 50-volt 60-watt lamps, on the base of the articles by Mr. C. Hering, entitled "Practical Deductions from Franklin Institute Tests." I took the diameter of armature from mechanical considerations, and then assumed a certain induction (in volts per foot) of active armature wire, which I took to be one-fourth of the whole length of wire on armature; dividing this by distance moved by armature in one second gave induction at one foot per second, and multiplying this by 100,000,000 gave lines per square foot, which divided by 144 gave lines per square inch of polar surface. The magnets I designed from experiments with small machines by a rule of thumb process. Now, I ask you, Sir, would this give reasonable results, or have I got hold of the stick by the wrong end? I must apologise for troubling you so frequently, but I am only able to get information up to date by your journal and the kindness of your contributors.—Yours, &c.,

G. T. PARDOE.

[Our correspondent has, we fear, adopted a procedure which cannot be relied upon to give him consistent results in general application. The diameter of the armature should be looked upon as the corner stone of the design, and the other quantities must be governed thereby. Mr. Fricker's papers show how this may be done in a perfectly general manner. It is not possible to predict the results of a dynamo from the information given by our correspondent, though we should be glad, if possible, to render him any further assistance in our power in the way of explanation.—ED. *E.*]

THE LIGHTING OF TURIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to a notice in your issue of the 22nd of April of a communication from a correspondent at Milan, which, being incorrect as to the facts, is likely to mislead and thus injure this company. I therefore beg you to give publicity to the following rectification:—A contract entered into between this company and the municipality of Turin for the lighting of a part of that city had been transferred by this company to Messrs. Bellani Fréres. When, however, Mr. Gaulard went to Turin to put the installation into working order, he found that the cable, which had been furnished by Messrs. Siemens and Halske, of Berlin, could not support the current for which the secondary generators were designed, the consequence being that the cable burnt. Mr. Gaulard offered to alter the secondary generators to suit a current the cable could support, but finding that Messrs. Bellani, although acting as agents of this company, had already on their premises transformers of Messrs. Zipernowski, Déri et Blatby (whom we consider infringers of our patents, and with whom we have suits pending in different countries), applied first to the municipality to verify by a scientific committee the complete and perfect working of our apparatus under the conditions for which they were constructed.

This inquiry, however, Messrs. Bellani opposed, and the whole question is therefore now being submitted to the law courts.

You will understand from the foregoing how unfair it is to imply that the alleged attempts to light a portion of the city of Turin with the Gaulard-Gibbs system were unsuccessful through any fault in that system, which is now sufficiently proved in many installations which are working perfectly.—Yours, &c., J. E. PICKERING, Sec.

National Company for the Distribution of Electricity by Secondary Generators, May 17, 1887.

SECONDARY BATTERY QUESTIONS IN BELGIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 2 of last week's issue of *The Electrician*, in connection with the above subject, the following remarks occur:—"The use of oxide of lead is certainly open to the public, since it has been shown that M. Planté had employed this method in the course of his researches long before M. Faure had dreamt of his patent." Will your Brussels correspondent kindly oblige by giving the authority from which he quotes the above remarks? For some time hints have been thrown out from reliable quarters as to the validity of the Faure patents. If, as stated, the only claim is the method of attaching and retaining the red lead, there is still some hope for a perfect secondary battery, a thing that does not exist at present. Very little interest is being taken in the improve-

Digitized by Google

ment of grids by practical mechanics, as it is generally felt that the present monopoly is valid.—Yours, &c.,

INTERESTED.

ELECTRICAL PHENOMENA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think your correspondent "Leakage" will find that the sparks he refers to have nothing to do with the dynamo at all, but are due to high-tension electricity from the belt. I have frequently drawn sparks from my belt half way between engine and dynamo by holding an iron rule near it, and have been informed by a friend that he has frequently observed the same phenomenon with belts of wood working machinery running at high speed in dry weather.—Yours, &c.,

R. H. C. NEVILE.

Wellingore Hall, Grantham, May 15, 1887.

VOLTS AND CALORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to apologise for supposing that our eminent electricans might be right (after correcting their diatomic blunders) in assuming any reasonable relation to subsist between 23,000 calories and one volt, or, as some prefer to have it, 46,000.

I now find the whole contention to be a flagrant mistake, and for pure lovers of science and common sense, it may be instructive to inquire whether this confusion be not a characteristic effect of the high and abstract methods in which our leaders delight to hide themselves from a common gaze or appreciation.

A *calorie* is a definite amount of heat, resulting from a definite amount of combustion; whereas a *volt* has an indissoluble relation to a current, and is nothing apart from time. One *volt* is the unit of power required to perform unit work in unit time, or, in other words, it is that amount of power which is requisite to drive an ampere of current through an ohm of resistance in one second.

And if this must be compared with calories—an attempt which is probably unwise—then it must be with calories per second, and instead of 46,000, we shall find the volt or volt-ampere relation to subsist with less than one-fourth of a calorie.

If this really be the case, is it worth while to continue these interminable discussions and personal recriminations for a purely mistaken object?

Having investigated this problem from original considerations, I am pleased to find the unexpected issue to be in strict accordance with formulæ previously established by Mr. J. T. Sprague and Mr. D. FitzGerald; but it may assist and encourage some students if we repeat the unfashionable process which does not extend beyond the "Rule of Three." I sought to analyse several batteries (on paper) with different potentials and varying resistances in order to find that one *volt-ampere* invariably means a consumption of 19 grains of zinc or other equivalent per hour, and $19 \div 15{\cdot}43 = 1{\cdot}231365$ grammes per hour, which $\div$ by $60 \times 60 = {\cdot}000342$ grammes per second.

I then find that this estimate is strictly confirmed by the recent and very elaborate experiments of Lord Rayleigh and others on the direct electrolysis of copper and silver.

The volt comparison proceeds upon the assumption that if we could find out the number of calories due to an equivalent of zinc when combusted, as in a battery, then this number would represent 1 volt. How such an absurdity could have passed current is amazing to think of.

The direct combustion of zinc = Zn + O (40·5) = 42,500 calories (M. Ditte estimates 44,122). The indirect combustion of zinc in a battery consists of Zn + O = 42,500—Cu + O = 21,885 = 20,615 calories, because for every atom of zinc oxide or sulphate formed there is a corresponding atom of Cu oxide or sulphate decomposed.

These numbers are only approximative, and vary with different authorities; but the *rôle* played by the acid is not fully understood. It is indispensable to dissolve the oxide of zinc as formed; it greatly adds to the conductivity, and in all probability contributes somewhat to the E.M.F. or volt-power. Prof. Silvanus Thompson estimates the total as 23,000, or $46{,}000 \div 2$; Mr. FitzGerald estimates 23,000, and Mr. J. T. Sprague has 23,287 calories.

Now, if we accept this basis, the result easily follows:—

(1) If 32·5 grams : 23,000 calories : ·000342 grams :: ·242 calorie.

(2) If 1 calorie : 3·073 ft.-lb. : ·242 calorie :: ·744 ft.-lb.

and by way of proof or corroboration we next find that 1 volt-ampere = ·2405 gram C heat units = ·737 ft.-lb.

We thus simply deduce the result, that 1 volt of power may be maintained by the expenditure of about $\frac{1}{4}$ calorie per second.

In *The Electrician*, April 15, 1887, p. 499, Mr. FitzGerald gives some kindred equations in absolute units upon the C.-G.-S. system. What that system is I do not know, nor do I care to know; but he wisely condescends to repeat them in our ordinary or practical units. He says, heat $= \frac{CE\theta}{4{\cdot}2}$ *calories*, also E (power) $= \frac{H \times 4{\cdot}2}{C\theta} =$ *volts*, or $E = \frac{H \times 4{\cdot}2}{96{,}600} = \frac{H}{23{,}000}$ *volts*. All this refinement is doubtless A B C to him, but it is not so to many ordinary students and workers; meanwhile, his $E = \frac{H \times 4{\cdot}2}{C\theta}$ *volts* really implies "that with unit current, in unit time, $\frac{1}{4{\cdot}2}$ calorie is expended for each volt, *i.e.*, about ·24 calorie."

I do not see that a more perfect corroboration could possibly exist; nor is it at all otherwise with Mr. J. T. Sprague, who has entertained the subject in his work on "Electricity" (2nd edition), where he shows that 23,287 calories, *continued* for 97,808 seconds, would equal ·238 calorie per second; which is another way of saying that "with unit current in unit time $\frac{1}{4{\cdot}2}$ calorie is expended for each volt," or, in either case, an expenditure of about ·74 ft.-lb. per second maintains 1 volt.

There is probably a simplicity and definiteness about volts which is not well approximated by calories, and, if so, why all this furor of mistake to compare the two things? Calories depend so much both on the antecedents and consequents of a given reaction as to render its determination often a matter of great difficulty.

For the enlightenment of Mr. Swinburne it may be well to repeat with emphasis my remark that whenever moderns are impelled or necessitated to appreciate the *real* relations, they invariably do so by a "hocus pocus" arrangement, which virtually conforms to the old or equivalent view of things.

This is evaded by a flippant assumption that the two views are equally true, that mass 9 of water = 34,000, as mass 18 = 68,000; that one is as good and true as the other, but that the latter best suits the views of modern chemistry.

On the contrary, we maintain that the two things are *different*, in the sense, that one is *true*, where the other is fanciful hypothesis. Mr. Shaw and Lord Rayleigh find that *the same electrolysis* which deposits 1 of copper may also deposit 3·4 of silver.

Now *this ratio* is a fact in nature, and in accordance with all other chemical truth; but it necessitates the "hocus pocus" when the atomic weights *are supposed* to be as 63 to 108. It is precisely thus with Mr. Sabine, who found by *observation* a 10 per cent. enlargement of volume; but without the "hocus pocus" he could not have derived the same 10 per cent. from *calculation*.

These, however, are only faint ways of showing the validity of this contention as compared with the overwhelming evidence supplied by the widest assemblage of chemical facts.

Yours, &c.,

SAMUEL E. PHILLIPS, F.C.S.

NOTE ON THE REGULATION OF SERIES-WOUND TRANSFORMERS BY "INDUCTION-RINGS."

The method of regulating series-wound transformers, described in *The Electrician* of April 29th (in which lamps switched off are replaced by coils whose virtual resistance is equal to that of the lamps), will be found on examination to present some rather curious points. From the practical point

Digitized by Google

of view the method of obtaining regulation is remarkable, from the fact that perfect regulation is obtained with an absolutely inappreciable loss of power. The following table contains some figures calculated from the data given in the article alluded to above, as follows :—

Mean alternating difference of potential at terminals of secondary coil	100 volts.
Actual resistance of each ring	1 ohm.
,, ,, ,, lamp	160 ohms.
Current through each lamp or ring in circuit	·625 a.
Total number of lamps	16.
,, ,, rings	16.
Periodic time of alternations	·01 sec.

TABLE I.

Lamps in circuit.	Rings in circuit.	Resistance of external circuit.	Work done per second (I^2R) under alternating E.M.F. of 100 volts. In lamps.	Work done per second (I^2R) under alternating E.M.F. of 100 volts. In rings.	Work done per second in the same circuit by a continuous E.M.F. of the same value.
n.	m.	Ohms.	Watts.	Watts.	Watts.
16	0	10	1,000	0	1,000
12	4	0·48	750	0·78	2,080
8	8	0·165	500	2·34	6,050
4	12	0·124	250	3·12	8,060
1	15	0·071	62·5	4·56	14,050
0	16	0·062	0	6·24	16,000

In this table the values of the work done both in lamps and rings is found from the square of the known current in each into their respective resistances, and for the sake of comparison the work which would be done by the equivalent continuous E.M.F. is added in the fourth column. It is at first a little startling to find that the continuous E.M.F. does work at the rate of about 21·5 horse-power in a circuit where the same E.M.F., if alternating with a period of 0·01 second, yields only 6·24 watts.

TABLE II.

Lamps in circuit.	Rings in circuit.	Coefficient of self induction of external circuit.	Total work done per second by Alt. E.M.F. (calculated directly from formulæ below).
n.	m.	L_0	Watts.
16	0	—	1,000
15	1	·00112	939
12	4	·00632	752
10	6	·01116	630
8	8	·01600	503
4	12	·01896	254
2	14	·01778	130
1	15	·01680	69
0	16	·01600	6

In Table II. the coefficients of self-induction for the external circuit are given in the third column. These were found on the assumption that the coefficient for a lamp is negligible in comparison with that for each ring, and the latter coefficient is taken as 0·254, this being the value required to fulfil the condition that the current through a ring shall be the same as that through a lamp.

It will be observed that the value of L_0 does not increase continuously with the number of rings in circuit; the physical meaning of this peculiarity can, however, be better explained when we come to consider the effect of the rings upon the *curve of alternation* in the remaining lamps, which we hope to do in a later note.

Before showing how L_0 is calculated, we may turn to the last column in this table, which gives the *total* rate at which energy is expended in the circuit. The figures in the column should obviously be equal to the sum of the second and third columns in Table I.; but the verification is not in every case exact to the last unit owing to the use of the slide rule. It is, however, quite sufficient to afford ample proof (if such is required) of the correctness of the method. In Table II. the work is calculated from the formula

$$W = \frac{E^2 R}{R^2 + \left(\frac{2\pi L}{T}\right)^2}$$

an expression which it will be noticed when $L = 0$ reduces to the ordinary formula for continuous E.M.F.'s. It is also, perhaps, worth noting that the denominator in this expression is the square of the virtual resistance.

If, however, the circuit contains branches then we shall have to calculate the value of L before we can use the formula. The simplest case is that in which there are n branches all having the same values of R and of L. In this case we have only to write R/n for R, and L/n for L. But when the resistances or self-induction of the branches are no longer all equal, then not only must the self-induction of the circuit be separately calculated, *but the value of R to be used in the expression for W is no longer that of the true resistance of the circuit.* In fact, to solve the problem we have to find the resistance and self-induction of an *equivalent* single circuit, that is *a circuit without branches which could replace the actual circuit without affecting either the E.M.F. or the total current.* It will be seen that the *equivalent* resistance of a circuit is quite different from its virtual resistance; both terms vary with the value of T, but the former has no meaning when referred to a simple circuit without branches.

Writing the equivalent resistance and coefficient of self-induction R_0 and L_0 respectively, the formulæ are as follows :—

$$L_0 = \frac{Q}{P^2 + p^2 Q^2}; \qquad R_0 = \frac{P}{P^2 + p^2 Q_2},$$

where

$$p = \frac{2\pi}{T},$$

$$P = \frac{R_1}{S_1^2} + \frac{R_2}{S_2^2} + \ldots\ldots$$

$$Q = \frac{L_1}{S_1^2} + \frac{L_2}{S_2^2} + \ldots\ldots$$

where R_1, R_2 . . . are the resistances of the several branches, and L_1, L_2 . . . are their coefficients of self-induction, while S_1, S_2 . . . . are their virtual resistances, the formula for which is well known. The values of L_0 in the case under consideration have been given in Table II. To find the coefficient of self-induction for the whole circuit we should merely have to add in each case the value of the coefficient for the secondary coil. It is, however, clear that this quantity will not be a constant unless the resultant magnetisation of the core lies upon the straight part of the curve. It may be interesting to give also the values of R_0, although it seems doubtful whether they have any physical meaning. The third column contains the true resistance of the circuit for comparison.

TABLE III.

n	m	R	R_0
16	0	10	10
15	1	0·92	10·6
12	4	0·48	12
10	6	0·245	11·7
8	8	0·165	10
4	12	0·124	4·06
2	14	0·083	1·67
1	15	0·071	0·78
0	16	0·0625	0·0625

W. H. S

THE MICRO-TELEPHONE PUSH-BUTTON OF DR. CORNELIUS HERZ.

(Concluded from page 17.)

When the number of stations passes a certain limit, the necessity for a central station appears, and the instrument lends itself readily to this method of working.

The system which we are about to describe is the one which for more than six months has worked very satisfactorily at the office of our contemporary. The installation includes a battery of four Leclanché elements, and an annunciator table of 16 micro-telephonic stations. Connections are made with the editorial office, the printing works, the public department, and the porter's lodge. Each station is connected with the annunciator table by means of four wires, the connections being established according to the plan shown by Fig. 15. The drawing shows all stations connected to the central office—any two stations can, in fact, be connected together permanently. The letters I, T, M, indicate the microphone, the induction coils, and the automatic switch, *b* the call push of the micro-telephone, and *d* a second call push placed above the micro-telephone push represented in Fig. 1. This second push allows the central station to be called even when permanent communication is made with one of the other stations of the system. The central station (Fig. 14) comprises a battery, P, a micro-telephone button, with bell, similar to those of the other posts, and a number of annunciators equal to that of the posts. Beneath each annunciator is a commutator for connecting any two stations. These connections are made by flexible single wire cords, terminated by plugs F (Fig. 14). With these explanations

Digitized by Google

it is easy to understand the working of the system when the call-button, *b*, of one of the posts is pressed. The plate *d* (Fig. 17) falls, showing the number, since in pressing *b* the circuit is closed between B and C (Fig. 17) which contains the electro-magnet E. The central station connects any two stations when the two plugs F, terminating the flexible cord, are inserted in the holes corresponding to their numbers (Fig. 17). This breaks at each station the connection of the lines C and D, and establishes

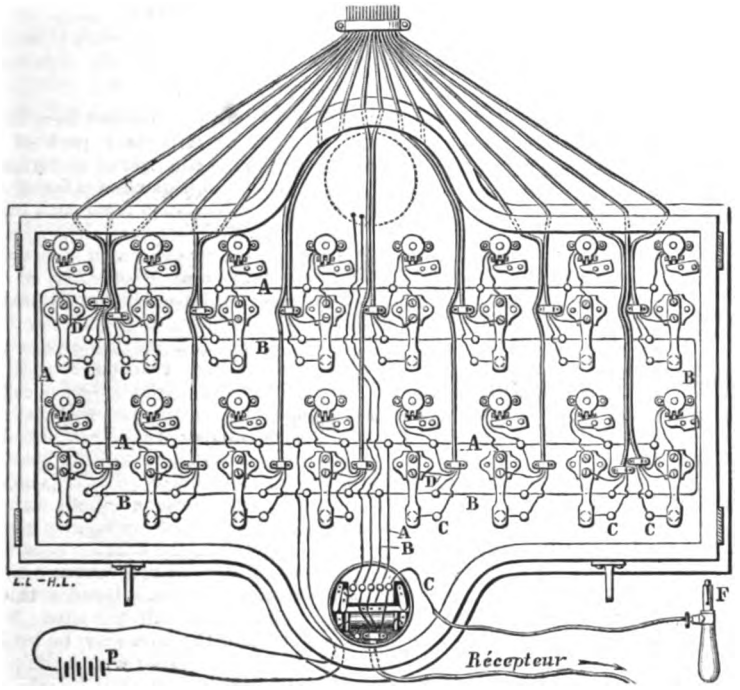

FIG. 14.

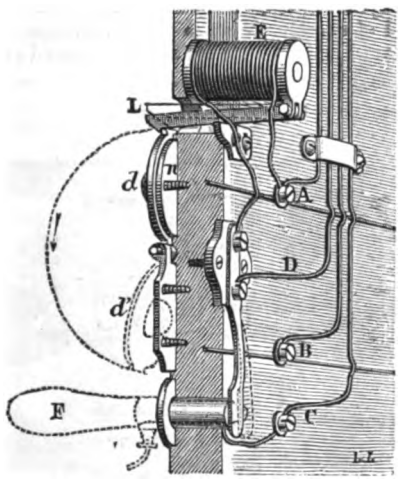

FIG. 17.

of this wire each station remains constantly connected with the central station, and by pressing the call button *d* the latter can be communicated with.

It now only remains to describe the micro-telephone, which has been designed in order to avoid as far as possible the necessity for adopting a constrained posture when holding a conversation by telephone. The instrument is shown in Fig. 16, which represents the entire apparatus

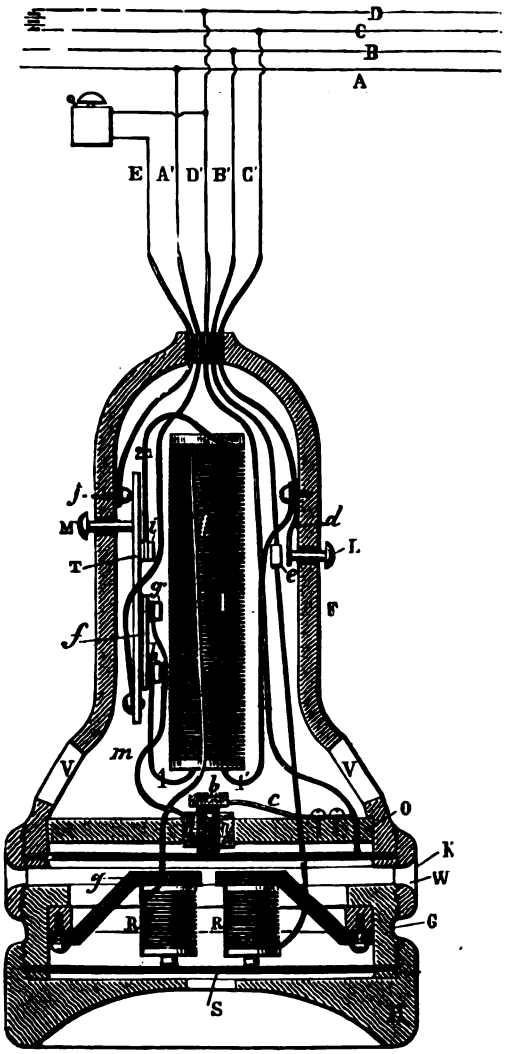

FIG. 16.

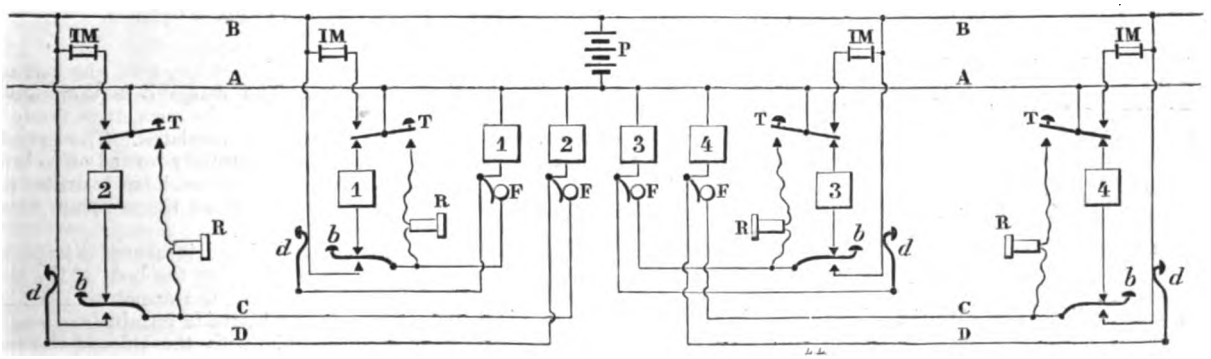

FIG. 15.

the continuity of the line C from one station to the other. The two stations are thus joined by three wires, as shown in Fig. 5, and they can call each other, and by unhooking their telephone pushes enter into conversation.

If there were only three wires, A, B, C, two stations connected through the exchange could not call the latter to ask to be connected to other stations. Hence the necessity for the fourth wire, D (Fig. 15). By means

required for one station, each set being contained in a single wooden case, having the form of an ordinary receiver, but somewhat enlarged. The handle F contains the induction coil I, the call push L, and the push M, which controls the switch by which the bells are cut out of circuit. Without entering into precise details as to the operation of this switch it will be sufficient to say that when the button is pushed in the small microphone *a b* connected with the diaphragm K is brought into circuit at

Digitized by Google

the same time. Below this diaphragm is the receiver H, with coils R R and diaphragm S. At the back of the microphone there are a series of openings, V V, through which the sound waves reach the carbon.

The mode of using the apparatus is as follows:—The operator holds the instrument in his hand in such fashion as to close the button L. Contact is thus made between *d* and *e*, which closes the battery circuit and rings the bell at the second post. The operator at the second station, taking his instrument in hand, also presses the push L, ringing the bell in reply. The operators then each allow L to rise, and press M, which brings their microphones into circuit. For the first station the circuit is as follows: From the battery through line D, diaphragm K, microphone contact *a*, wire *n*, the contacts *g'*, *f*, *h*, the primary circuit of the coil, the spring *d*, and the line C. The circuit of the second station is precisely similar. The circuit common to the two receivers, normally open at at *i*, is now closed through the commutator T; this circuit is completed beyond the apparatus by the lines A B.

The apparatus may be held to the ear during the whole time of the conversation, and it is merely necessary to speak in an ordinary tone of voice; the sound waves spreading in all directions, pass through the openings V V, no matter in what direction the voice is uttered.

THE SLATER-LEWIS INSULATOR.

This insulator may now be regarded as a practical success, having withstood the most severe tests over a period of about four years. It will be seen from the illustration that the usual iron stud is screwed into the insulator instead of being secured by cement. The idea, however, is not exactly new, inasmuch as Mr. Cordeaux patented a similar design some seven or eight years ago, but with the addition of an india rubber washer placed on the shoulder or upper gallery on the iron bolt which supports the cup. This washer or cushion is for the purpose of protecting the porcelain threads from a dead pressure, to allow for expansion and contraction of the sundry parts, and to protect the threads from moisture and consequent rust. This rubber cushion or washer Mr. Lewis dispenses with altogether, employing nothing except the porcelain cup and the iron bolt. This is accomplished through a slight modification in the construction of the parts, and by reason of automatic machinery, which cuts the threads with unerring accuracy—a condition absolutely indispensable for the manufacture of a perfectly satisfactory insulator, because the slightest outward or upward pressure will force off the top of the cup.

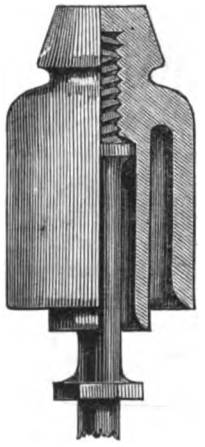

FIG. 1.

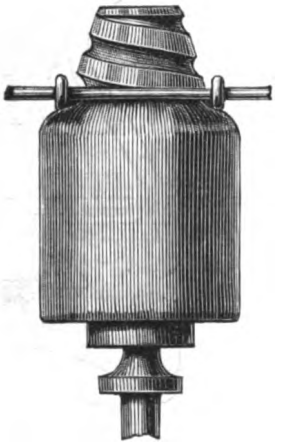

FIG. 2.

The new insulator, Fig. 1, when fixed, is brought down to a solid bearing, and the cup sits perfectly upright in its seat, whereas with the rubber washer a solid bearing is impossible; therefore there is (especially round sharp curves in the line wires) a strong tendency to pull the insulator aside and out of truth with the support, thus throwing great pressure on the porcelain threads, and causing, in many instances, complete fracture. This condition of things grows worse as the rubber deteriorates, and the decay goes on, until finally no rubber whatever remains, and the insulator is left to rock about on the stud to the damage of chafing the wire and ripping the earthenware threads.

The importance of dispensing with the rubber altogether is therefore fully apparent. About 200,000 of these insulators have already been sold to various railway, telegraph, and telephone companies at home and abroad, and repeated orders on a large scale are being constantly received. A large number of these insulators have been under trial on the postal telegraph lines for some years, and a further quantity are now being supplied under contract with the owners of the patent, the Telegraph Manufacturing Company.

The insulator is also supplied with patent self-binding screw tops, by means of which a perfectly rigid attachment is instantly made. The cups can afterwards be renewed or taken down for washing without disturbing either binder or bolt. This is effected by an arrangement of a right-hand screw on the bolt and a left-hand screw on the insulator.

This arrangement is shown in elevation in Fig. 2.

AN EIGHT-LIGHT DYNAMO.

BY GEORGE M. HOPKINS.

(*Continued from page 13.*)

The making of a good commutator is not the smallest item in the construction of a dynamo. It is a very important part of the machine, requiring good workmanship and the best of materials.

The commutator cylinder in a machine of this class is formed of a series of bronze bars, separated a short distance from each other, and carefully insulated. On the eight-light dynamo it is 1¼in. in diameter and 2in. long. The bronze sleeve A, which is fitted to the shaft and provided with a fixed flange and a set screw at one end, is screw-threaded at the opposite end to receive the screw-threaded bronze flange B. On the sleeve A, between the fixed flange and the removable flange B, is placed a vulcanite sleeve, C, and to the ends of this sleeve are fitted two collars, D, of vulcanised fiber or analogous insulating material. These collars are bevelled on their inner surfaces, and are thickest at their peripheries. To the vulcanite sleeve C is fitted a bronze cylinder, E, having conical ends, fitted to the bevelled collars, D, as shown at 5 in Fig. 6. The bronze cylinder is slitted longitudinally in a gear cutter, or in any other convenient way, so as to divide it into 24 equal divisions, the slits extending nearly through the cylinder, as shown at 1. Before the bars are separated they are marked with figure punches, in regular order from 1 to 24, so that they may be rearranged after separation. Besides this, a sheet of mica is selected which can be crowded into the slits. Now, if the slits have been made deep enough, the bars may be broken off one after another, and the fin may be removed with a file; but if the bars cannot be broken off in this way they may be removed by means of a hack saw, as shown at 2.

As many strips, F, of mica are cut from the sheet as there are bars in the cylinder, the mica strips being made a little wider than the bars and of exactly the same length, as shown at 3.

The commutator bars thus formed are placed between the collars

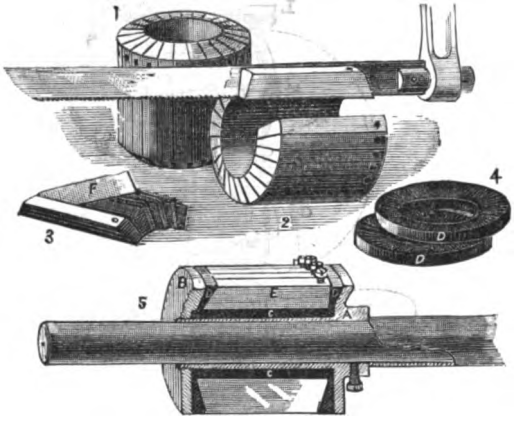

FIG. 6.—The Commutator Cylinder.

D D in alternation with the mica strips, with the bars arranged according to their numbers. The flange B is then screwed up tightly, clamping all the bars and the mica strips firmly in their places, each bar being thoroughly insulated. The cylinder thus made is placed upon an arbor and carefully turned off to bring it to a true cylindrical form. After turning, each bar is drilled near one end to receive the brass screw by which the armature wire is connected with the commutator bar.

The commutator cylinder, now finished, is secured in its place on the armature shaft with the screws adjoining the body of the armature.

Now, for convenience in handling, the armature shaft is placed in the lathe, and the inside and outside terminals of one coil are carefully straightened out parallel with the sides of the armature, and their ends are stripped of the insulating covering for a short distance and thoroughly scraped. The screws in two of the commutator bars, say 1 and 2, are loosened so as to permit of placing the looped ends of two wires under them. The outer terminal of the coil is connected with one of the screws, and the inner terminal of the same coil is connected with the screw in the next bar in order in the commutator cylinder. The outer terminal of the second coil is connected with the screw last referred to, and the

Digitized by Google

inner end is connected with the screw of the next bar in advance, and so on around the entire commutator cylinder, the outer end of each coil being connected with inner end of the adjacent coil, and with a bar of the commutator cylinder by one of the screws, as shown in Fig. 7.

The brushes which bear upon opposite sides of the commutator cylinder are each made of six thin strips of hard rolled copper ½in. wide, and 3in. long, split from their free ends towards their clamped ends, to render them more elastic. The brushes are clamped in morticed studs passing through holes in the ends of a bar fitted to and adjustable on a boss formed on the inner side of the bronze yoke around the shaft. By this arrangement the brushes may be adjusted for taking off the current to the best

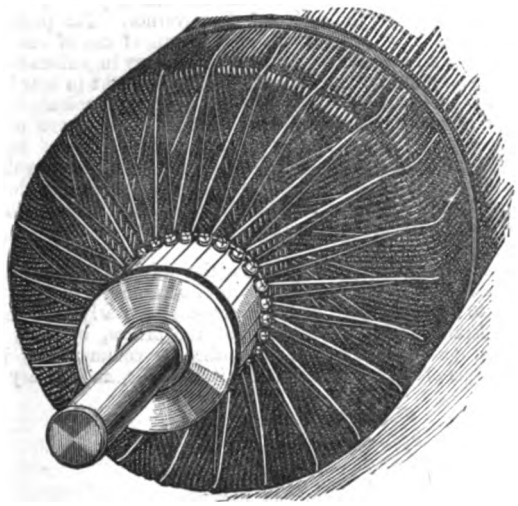

Fig. 7.—Connections of the Armature Coils and Commutator Cylinder.

advantage. The mortised studs which hold the brushes are separated electrically from the bar by insulating thimbles and washers, and upon the outer ends of the studs are screwed binding posts, in which are inserted conductors, bent into spirals to permit of the adjustment of the brushes. One of these conductors communicates with one of the binding posts on the machine base, while the other communicates with one of the rods extending to the top of the field-magnet. The remaining binding post on the base is connected with the other vertical rod, extending to the top of the magnet. These vertical rods are connected with the terminals of the winding of the field-magnet, as shown in Fig. 1.

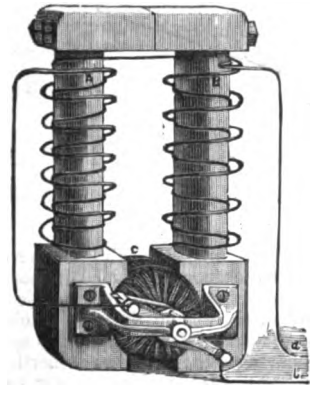

Fig 8.—Circuit of the Dynamo.

The circuit of the machine is clearly shown in Fig. 8, the current passing from the armature C, through the upper brush, thence to the top of the arm A of the magnet, down that arm, then up to the top, then down the arm B, and up, then downward to the base of the machine, terminating at *a*. The lower or remaining brush is connected with conductor *b*. From the terminals *a b* the current is taken off for use.

In Fig. 8, for the sake of clearness, only a single conductor is shown on the field-magnet, but in practice there are four, each conductor passing down and up once on each arm of the magnet—that is to say, there are eight layers of wire on each arm of the magnet, formed of four wires, each wire being laid on by beginning at the yoke, winding down to the shoulder of the polar extremity, then up again to the top, leaving the inside and outside ends projecting, as shown in Fig. 9. The winding is best done in a lathe.

In the present case all of the inner ends of the wires of the arms of the magnet are connected together, and all of the outer ends of one arm of the magnet are connected with one of the vertical rods, while the outer ends of the wires of the other arm are connected with the other vertical rod, as shown in Fig. 1.

By winding the field-magnet with No. 18 wire in the manner described, several advantages are secured, one of which is the facility with which the work of winding may be done; another is the possibility of connecting the wires in different ways so as to secure more or less resistance in the magnet. Another is that the wires may be conveniently connected up according to the various methods of winding, compound, shunt, series, &c.

As shown in the engravings, all of the wires of the field-magnet are in parallel circuit, practically forming a large conductor of small resistance, and the conductor thus arranged is connected in series with the armature—that is, the current from the armature passes directly through the field-magnet and external circuit.

Having made the dynamo and connected it up in the manner described, the brushes are to be brought into contact with the commutator cylinder at points diametrically opposite each other, and at points about opposite the centre of the space between the polar extremities of the field-magnet. The armature is revolved in the direction of the free ends of the brushes, and in the binding posts on the base are inserted short wires, which may be brought into contact with each other momentarily as the armature revolves.

If a spark is seen on the separation of the wires it shows that the magnetism inherent in the iron of the field-magnet is sufficient for the starting of the machine, and no further manipulation other than the adjustment of the brushes is necessary. The brushes should be adjusted to a point where the least sparking is produced. This will not vary much from the original position. The machine from which the engravings were made produces no noticeable sparks at the commutator.

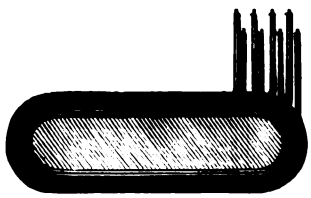

Fig. 9.—Section of One Arm of the Field-Magnet, showing Winding.

If the machine fails to start when tried in the manner above indicated a battery of four or five Bunsen cells must be connected with the binding posts, or a dynamo may be used instead of the battery. It sometimes requires a few minutes to start the current, but as soon as it begins the battery should be removed.—*Scientific American.*

MODES OF MEASURING THE CO-EFFICIENTS OF SELF AND MUTUAL INDUCTION.*

By Profs. W. E. Ayrton, F.R.S., and John Perry, F.R.S., Members.

(*Continued from page 21.*)

These series of experiments have been made simply for the purpose of experimentally investigating the law of the instrument, and it is of course not at all necessary to make all these observations for the purpose of measuring the coefficient of self-induction in any particular case, nor is it necessary that the commutator should be able to be run at a number of known speeds. If the instrument is to be used to measure coefficients of self-induction the values of which do not vary between very wide limits, then it is sufficient if the instrument be constructed so as to run at one fixed speed which is not too high for the currents to become steady with the largest coefficient of self-induction that the instrument is designed to measure. If the instrument be required to measure coefficients of self-induction all having rather a large value, and also coefficients of self-induction all having rather a small value, then it would be desirable to construct the instrument so that it would run at either one low known speed or at one high known speed. The greatest sensibility in the measurement of coefficients of self-induction of which the values range within wide limits is obtained by constructing the instrument so that it can run at a number of known speeds. In practice, such a wide range instrument would be used as follows:—Before the instrument left the maker's hand the lead would be fixed and experimentally accurately determined once for all, and $60 \times l$ might be called the constant of the instrument K. An experimenter, in determining the coefficient of self-induction of any coil would—

First. Measure the resistance of the coil in the ordinary way.

Second. Rotate the instrument at some convenient speed, which must be noted, say N revolutions per minute, and by altering the resistance in one of the arms of the bridge until the galvanometer needle again comes to zero, observe the apparent increase of resistance of the coil, σ say.

Third. Rotate the instrument at some other convenient measured

* Paper read before the Society of Telegraph-Engineers and Electricians on April 28th, 1887.

Digitized by Google

speed, say N′, and measure the apparent increase of resistance of the coil, say σ', above its original value.

Then if $\frac{\sigma}{N} = \frac{\sigma'}{N'}$, the apparent increase of resistance obtained with either speed may be used, and the required coefficient of self-induction $= K\frac{\sigma}{N}$; if, on the other hand, $\frac{\sigma}{N}$ is larger than $\frac{\sigma'}{N'}$, then the speed N′ is too high, and possibly also is N, to give accurate results. Therefore use a speed N″ lower then N, and measure the new increase of resistance σ''.

If now $\frac{\sigma}{N} = \frac{\sigma''}{N''}$ the speed N was not too high to give accurate results, although N′ was; hence the apparent increase of resistance obtained with either speed N or N″ may be used, and the required coefficient of self-induction $= K\frac{\sigma}{N}$.

If $\frac{\sigma}{N}$ be only a little *greater* than $\frac{\sigma'}{N'}$ and if N′ *much exceeds* N, then it will not be necessary to make a third experiment at the lower speed N″ unless very accurate results are desired, for the coefficient of self-induction can only be a very little greater than $K\frac{\sigma}{N}$, which may therefore be practically taken as the correct value.

By the simple addition, therefore, of such a commutating arrangement as we have described to an ordinary Wheatstone bridge, it becomes possible, whenever the resistance of a coil electro-magnet, &c., is being measured, to measure also the coefficient of self-induction in absolute measure, by a zero method which is as sensitive for the measurement of self-induction as the ordinary Wheatstone bridge method is for the measurement of resistance.

From what precedes it follows that

$$L = K\frac{\sigma - \sigma''}{N - N''};$$

so that if s_1, s_2 be the apparent resistanees of the coil at two speeds, N_1, N_2 revolutions per minute, the speeds not being too large,

$$L = K\frac{s_1 - s_2}{N_1 - N_2};$$

hence *the coefficient of self-induction can be determined from two experiments made with the revolving double commutator without knowing the true resistance of the coil at all.*

If there be doubt as to whether the speeds N_1 and N_2 are too large, a third check speed, N_3, may be used; or instead, as explained in Appendix II., a rough test of the resistance of the coil for steady currents may be made; but time need not be spent in obtaining an accurate balance, as quite a rough balance can be used as follows:—Let O on the scale be the true zero for no current passing through the galvanometer, and let the spot of light be at, say, 156 divisions when an approximation is made to balance for steady currents, the resistance of the coil appearing to be s ohms, then the zero to be used in making the *second* and *third* tests just described is $l \times 156$, where l is the lead and σ is to be reckoned as the increase above the approximate value of the resistance for steady currents.

Commercial Forms of the Instrument.

The long-range instrument previously described requires an electromotor to drive it, and a speed-indicator to register its speed, hence it would be too cumbersome for everyday work. Further, as it is very difficult to maintain the absolute constancy of the speed of a small motor driving a friction brake, like our commutating arrangement, at a high-speed for any considerable time, in consequence of very slight variations in the friction of a high-speed brake producing marked variations in the speed, it requires two experimenters to use the form of our instruments already described; one to vary the resistance until the galvanometer needle comes to zero, and the other to note the speed of the motor at the moment that the first experimenter gives a signal that the galvanometer needle is at zero.

Hence, in the autumn of last year, we were led to consider what form should be given to the commercial instrument to be used for the measurement of self-induction in this way. The main condition of the problem was that the instrument should be able to be used by one experimenter *alone*, since one experimenter alone can measure a resistance with a Wheatstone bridge, and therefore we felt that if another experimenter had to be summoned when a coefficient of self-induction had to be measured, the instrument would lose much of its practical value. Our first idea was to employ clockwork that would drive the commutating arrangement at various fixed speeds, determined by the adjustment of a certain powerful governing arrangement, and to this end commutators of very small diameter were constructed, so as to waste only a small amount of power in friction and interfere but little with the action of the governor. The problem at first sight appeared an easy one, but the experiments of one of our assistants, Mr. Bourne, whom we have to thank for the many ingenious devices that he has suggested, and for the skill that he has brought to bear in the construction of the various experimental forms that the apparatus has passed through in its development, showed that in consequence of the high speed of the commutator, and of its acting as a friction brake, good results could only be obtained with clockwork of such unwieldy dimensions as to make it impossible for the instrument to be made portable; further, it was contrary to our engineering instincts to employ an apparatus which wasted so large a portion of the power required to drive it in the governing arrangements.

When making the experiments with the original commutating apparatus, two methods suggested themselves of obtaining a balance—the one, to try and to keep the speed of the electro-motor nearly constant, and to vary the resistance of one of the arms of the bridge, by trial, until the galvanometer needle came to zero; the other, to commence by increasing one of the arms of the bridge by a definite amount, and to vary the speed of the electro-motor, by trial, until the galvanometer needle came to zero; and it soon appeared that the second method was the one that would have to be adopted in a practical instrument, since, while it is very difficult to maintain a constant speed, there is no difficulty in obtaining a gradually diminishing or increasing speed. For example, the apparatus may be provided with a fly-wheel having a large amount of inertia, and may be driven by hand more or less fast until the galvanometer needle comes to zero. The next step in order to avoid the necessity of a second experimenter was to devise a *recording speed-indicator*, and the best form that we have arrived at is based on the principle that we employed in constructing an apparatus some years ago for experiments on centrifugal force, described at a meeting of the Physical Society at the time, and in regular use in the mechanical laboratory of the Finsbury Telegraph College ever since, for experiments on centrifugal force.

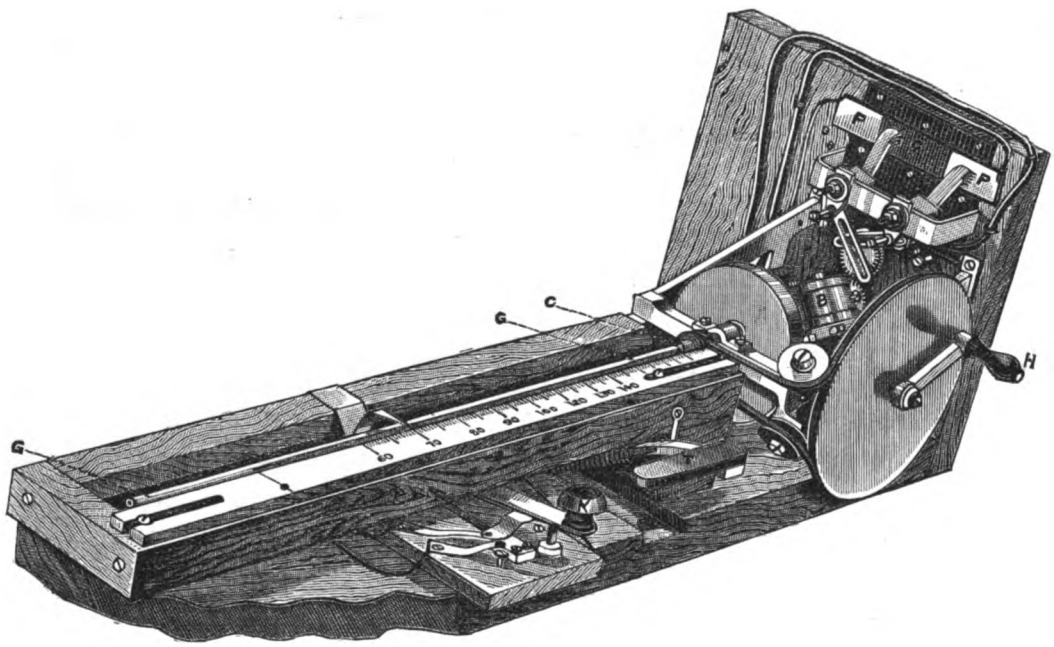

Fig. 5.—Experimental Secohmmeter.

Attached to the commutation of our self-induction apparatus is a box, B (Fig. 5), fitted with weighted elastic sides made of corrugated steel, which fly out more and more under the action of centrifugal force, as the box is rotated faster and faster. A stout glass tube, G, of comparatively small bore, open at both ends, is cemented into a collar in the axis of the box, and rotates with the box. The box is completely filled with mercury, and the tube partially, hence the volume of the box expands as its sides fly out and the length of the column of mercury in the tube diminishes, so that the length of the column at any moment is a measure of the speed of rotation of the box. In the neck of the collar, C, in which the tube is cemented, there is a steel tap attached to an axial spindle passing through a tube inside the box, and projected out of this tube at the other end of the box. If this spindle be turned relatively to the box, the

Digitized by Google

tap is opened or closed. At the commencement of an experiment the tap is opened, and the handle H is turned with the right hand, faster and faster, until, on depressing the key K with the left hand from time to time, the galvanometer needle is seen to be approaching zero, or the spot of light the zero position on the scale. The key may now be kept depressed, and on turning the handle a little faster a speed is at length reached producing exact balance—if the handle be turned faster, the needle or spot of light deflects to one side of the zero, if more slowly to the other—at this moment the trigger T is lightly touched with the left hand and a spring is liberated. This has the effect of producing a resistance to the rotation of the tap-spindle, which previously was rotating freely with the rotating box, and the tap is thus turned off, cutting off the connection between the mercury in the glass tube and that in the box. Consequently the mercury in the tube remains, even after the instrument is stopped, of exactly the same length that it had when the trigger was touched. *The position of the end of thread of mercury in the tube is now read off on the scale attached, and the apparent increase of resistance of the coil, electro-magnet, or whatever it may be, divided by the number on the scale, gives the required coefficient of self-induction in second-ohms without any further calculation.*

The instrument is therefore *direct reading.*

This first form of recording speed-indicator was designed to be used vertically, as may be seen from the figure, but we soon found that great advantages were to be gained by placing it *horizontal.* If the glass tube be vertical the mercury in the tube exerts a pressure on the elastic sides of the box, which diminishes as the mercury falls on the speed of rotation being increased. This diminution of pressure causes the mercury not to fall so much for a given speed as it would were there no variation in the pressure due to the mercury in the tube, and so it diminishes the sensibility, hence we have been led to employ a horizontal tube. Further, since the mercury in a horizontal tube exerts no pressure on the elastic sides of the box, the amount of mercury in the tube does not in any way affect the sensibility, provided that the scale is so placed that the zero is opposite the end of the thread of mercury when the box is at rest. Hence, should any spilling of the mercury by accident occur when the instrument is moved about, the accuracy of the readings is not altered, so that by placing the tube horizontal we obtain greater sensibility and constancy in the readings.

Variations in the temperature from day to day cause alterations in the volume of the mercury, and so alter the length of the thread of mercury in the tube, but this also introduces no error in the experimental result, nor difficulty in using the instrument, since before the commencement of the experiment the scale is slightly moved until the zero on it comes opposite the position occupied by the end of the thread of mercury on the day in question when the box is at rest.

At first, rotating commutators similar to those shown in Fig. 1 were employed with the apparatus shown in Fig. 5; next the brushes were made of a variety of different forms, so as to press *radially* on the rotating commutators to prevent the wear altering the lead, and thus changing the sensibility of the instrument; but this form of commutator has at length been entirely superseded by the two oscillating arms, or brushes, A, A, worked by a cam. Each arm is composed of several pieces of hard copper, contact being made through the ends, as in many of the switches now used for electric light work. The end of each brush alternately rubs on a flat piece of phosphor bronze, P, P, when it makes contact, and on a *flat* piece of glass or agate, *g*, when it does not. This form of commutator we found superior for our purpose to the double cylindrical one, since, with the two oscillating arms, the lead can be more easily varied for adjustment; and this slight adjustment of the lead, we may here mention, forms the fine adjustment in the construction of this direct reading instrument. Further, the slow wearing of this form of brush does not alter the lead, consequently the value of the graduations of the scale remains constant.

The lead aimed at in the construction of these instruments is $\frac{1}{4}$, as that gives an equal time to each operation, but in any actual instrument it may be made a little more or less than $\frac{1}{4}$, being slightly altered, as just explained, in the final adjusting of the instrument by the maker.

It might appear, at first sight, that the two ends of an oscillating lever, or the two prongs of a vibrating tuning fork, would perform the required makes and breaks in the right order, but a reference to the cycle of operations given in the table, page 18, and a little consideration will show that the two prongs of a tuning fork cannot perform the required cycle of operations in the correct order.

Following the precedent of naming an instrument after the name of the unit employed—for example, "ammeter," "voltmeter," "ohmmeter," "wattmeter"—it seems desirable to call this instrument after the name of the commercial unit of self and mutual induction. The absolute electromagnetic unit of self and mutual induction is one centimetre, a name used by all scientific nations. But the commercial unit of self and mutual induction is $99,777 \times 10^4$ centimetres, or second-ohm, which is a little less than 10^9 centimetres, or one earth's quadrant. Now, in spite of the difference between these two numbers, which, although small, it is a pity to lose sight of, the English word "quadrant" is not used in French, therefore it would not be well to suggest this word as the international name for the unit. Yet it is most important that some name should be universally adopted, since the use of simple familiar names has much to do with making people familiar with the laws of the effect measured by the unit. The unit of electrostatic capacity, the farad, has been called after the greatest experimental worker in electricity; it would, therefore, seem appropriate that the unit of electromagnetic capacity should be called after Maxwell, the greatest mathematical worker in electricity. We do not, however, like to propose this, as we feel there might be difficulty in obtaining the general acceptance of the name of an Englishman, however great, unless it were sanctioned by an international electrical congress, or unless the man's name was intimately associated in men's minds with self and mutual induction. And Maxwell's large contribution to the subject of electromagnetic induction is surrounded by his equally large contributions to all other branches of electricity and magnetism—a giant surrounded by giants is not prominent. Coming to the last two years, we are glad that the leader and all those who have followed him in taking part in the widening of our ideas in self-induction are still with us. Hence we are driven to suggesting a temporary name for the unit, and as the first three letters in "second" are common to the name in English, French, German, Italian, &c., and ohm is also common, we venture to suggest "*secohm*" as a provisional name, and our instrument we will therefore call a "*secohmmeter.*"

(To be continued.)

FIFTY YEARS' PROGRESS IN TELEGRAPHY.*

By W. H. Preece, F.R.S., Vice-President of the Society.

This is the Jubilee year of the electric telegraph in England. On July the 25th, 1837, the first practical trial of telegraphy was made between Euston and Camden, on the London and North-Western Railway, by Cooke and Wheatstone. Nine tedious years were spent in endeavouring to create enthusiasm among financial circles for this young and novel means of communication. The first company formed to develop the business of transmitting and delivering written telegrams was incorporated in 1846, and was called the Electric Telegraph Company. Wires were speedily extended to every great centre of trade along the great railways that were then being developed, and about 1851 the business was fairly established. Telegraphy and railways have grown up side by side. In 1851 submarine telegraphy was proved to be practical. Cables were laid in 1852 and 1853 to France, Belgium, Holland, and Ireland, and from that year domestic and international telegraphy grew and prospered. The Electric Telegraph Company suffered the fate of all prosperous initiators of that which is novel, useful, and successful. The validity of their patents was contested, the strength of their business was assailed all along the line by enterprising competitors. Their monopoly was broken, but the public gained by this active rivalry greater development of communication and considerable reduction of rates. We see the same process going on at the present day with respect to telephones, but with less success.

The rates for messages, which were as high as 12s. 6d. for twenty words, were based on a sliding scale. The rates for a message of twenty words were fixed at 1d. per mile for distances under 50 miles, then $\frac{1}{2}$d. per mile up to 100 miles, and $\frac{1}{4}$d. per mile for a distance of more than 100 miles; addresses forming part of the twenty words. A message to Glasgow cost $8\frac{3}{5}$d. per word, to Manchester $5\frac{1}{5}$d.

Various reductions took place from time to time. In 1864, that is in less than twenty years, three great companies competed in every principal town for this profitable business of telegraphy. The United Kingdom Telegraph Company was formed in 1861 to introduce the universal shilling rate; but the severity of the competition of their opponents was too great for this spirited company, and they had, in 1865, to submit to the following general tariff:—Within London and other towns, 6d.; within 100 miles, 1s.; within 200 miles, 1s. 6d.; over 200 miles, 2s.—addresses being sent free.

The public now began to suffer. Only the larger towns, where profitable business could be tapped, were served. The smaller towns were neglected, and great villages had to suffer the aggravation of seeing posts and wires pass through their main thoroughfares without being able to avail themselves of this speedy mode of communication.

Telegraphy became a necessity of the age for the due and proper transaction of business. It became so closely allied with other modes of communication that public opinion, in 1868-9, forced the Government to purchase and absorb all the telegraph companies, and to transfer their business to the care of the Post Office, which had shown itself so capable in dealing with letters and newspapers, and in establishing the penny post.

The telegraphs of this country again became a great monopoly; but there is a vast difference between a monopoly in the hands of a private speculative corporation, subject to no control but that of its own closed ring, and whose sole object is to earn dividends or to make money, and that in the hands of the Government, whose sole object is to serve their masters, the public, faithfully and well, and whose actions are incessantly supervised by the jealous and watchful eyes of those they serve, who have an equally watchful and much less tolerant press in which to air their wrath and grievances, and an active House of Parliament ever ready to counteract and reform real abuses when fairly and properly laid before it.

It is impossible to conceive supervision more complete than that to which the Post Office is subject. The receiver of every letter, the transmitter of every message, the editor of every paper, the reader of every news despatch, every householder or business man, can see for himself how his own business is conducted; he can growl and grumble to his heart's content at any error or delay that may occur, with a certain knowledge that his complaint has been heard, and, if just, remedied, although he may not always be satisfied with the attention he receives. The telegraphic business of this country has reached its present dimensions because the work has been done well, and it has been done well because the mode of doing the business has been so well and so thoroughly supervised by the public.

The transfer of the telegraphs to the State took place on February 5th, 1870. The tariff established by Parliament was a uniform tariff of 1s. for twenty words, addresses being sent free, and this tariff remained in force until October 1st, 1885, when the present simple word tariff of $\frac{1}{2}$d. per word, irrespective of distance, and including addresses, with a minimum of 6d., was introduced.

The average cost for the transmission of a telegram immediately before the transfer was 2s. $1\frac{1}{2}$d. After the transfer it was reduced to 1s. 1d. It is now 8d.

* Paper read before the Society of Arts, on Wednesday, May 18.

The number of offices open to the public prior to the transfer was 2,932, but owing to the existence of three large companies in the same town, the number of towns in telegraphic communication was probably not more than 2 500. There are now 6,514 offices open to the public. [See Appendix I.]

But the amount of business done is a better criterion of the benefits that the public have derived from the transfer of the telegraphs to the Post Office. At the close of the year 1870 the gross receipts of the Telegraph Department were £612,301; at the close of 1886 they were £1,787,264, and at the close of this year they will probably reach £1,950,000. The number of messages transmitted in 1869 were 6,000,000; in 1870 they were 9,850,177; in 1880 they were 26,547,137; in 1886 they were 39,235,813; and at the end of this year (1887) they will probably exceed 52,000,000. [*Vide* Appendix II.] Diagram I. exhibits graphically the rate of growth of messages and wires, and it illustrates pointedly the result of the ½d. per word tariff, whose success has exceeded all estimate and anticipation.

The development of telegraphy is better shown in our great central station than anywhere else. The following Table is interesting:—

Date.	One day's messages.	Instruments.	Staff.		
			Male.	Female.	Total.
Before transfer..	8,500	...	...	...	...
1870.....	12,000	350	280	485	765
1880.....	43,000	486	826	598	1,424
1886.....	98,570	945	1,490	802	2,292

The number of messages dealt with each day ranges from 70,000 to 100,000, nearly half of which are transmitted messages which have to be both received and forwarded, and therefore become, practically, two messages, although they count as only one in the total.

The local traffic in London—that is, messages emanating from one part of London for delivery in some other part, and passing through the central station—is very large. It ranges from 12,000 to 18,000 messages per day. In 1868 there were 60 offices open in the metropolis, dealing with 300 messages per day; there are now 480 offices, dealing with an average of 15,000 messages a day.

The total number of local metropolitan messages for four weeks was:—February, 1870, 138,534; January, 1880, 726,199; January, 1887, 1,277,838—a tenfold growth nearly.

Press Arrangements.

One of the great objections raised against the absorption of the telegraphs by the State was the difficulty which the Government would have in transmitting news. In no country is there now such a complete system of telegraphy for news purposes as there is in the United Kingdom. Two complete news circuits serve always (day and night) the following important centres from London:—

1. Newcastle, Edinburgh, Glasgow, Dundee, Aberdeen.
2. Nottingham, Sheffield, Leeds, Bradford.
3. Birmingham, Manchester, Liverpool.
4. Bristol, Gloucester, Newport, Cardiff, Exeter, Plymouth.
5. Brighton, Portsmouth.
6. Dublin, Cork, Belfast.
7. Northampton, Leicester, Derby.

There are several other groups in the provinces served from these centres, and every evening after six p.m. a third, and frequently, especially in the Parliamentary Session, a fourth circuit is made up to all these stations from London. Each office on each of these groups receives simultaneously the news sent from London. Thirty newspapers obtain the use of special wires, with clerks' services, from 6 p.m. to 6 a.m., many, like the *Scotsman*, the *Newcastle Chronicle*, and the *Manchester Guardian*, having two circuits; and whenever any great political event arises, such as the delivery of a great speech, all the important towns throughout the kingdom receive simultaneously a *verbatim* report of the speech. There is not a town in the country where a daily paper is printed which is not placed, after 6 p.m., in direct communication with London, and which does not deposit on every subscriber's breakfast table a nearly *verbatim* report of the previous night's debate in Parliament.

The press rates are very low. The average price paid is a little in excess of 2d. per 100 words. This entails a loss to the department roughly estimated at £200,000 a year, which is the amount the public is taxed for the support of the press. It is doubtful whether Parliament knew when it passed this low rate that it virtually meant a subsidy to the press. The loss might be very materially diminished if there were less competition and more union among newspapers and news agencies. As it is, the same matter has frequently to be sent twice over the same route, and the amount of unnecessary news sent, and therefore unnecessary expense incurred, is enormous, much of it finding its way into the waste paper basket. The supply of news before the transfer was very meagre. Reuter's telegrams, Parliamentary reports, general news, markets, races, were supplied for £200 a year. The companies did this jointly, and news was collected as well as distributed; but the Post Office is simply a carrier. It is not allowed to collect, and it has thus saved much of the obloquy that attached to the irresponsible monopoly of the telegraph companies. The average number of words supplied to each newspaper was said to be 4,000 a day. It is now roughly estimated at about an average of 12,000 in the recess, and 15,000 or 20,000 in the session.

The following will give some idea of the total number of words sent on one evening, on important political occasions, from the central station:—

April 8th, 1886.—Mr. Gladstone's Home Rule Bill, 1,050,500 words.
April 16th, 1886.—Land Purchase Bill, 841,500 words.
June 7th, 1886.—Irish Government Bill (Division), 863,700.

Appendix III. shows how rapid and great has been the increase in this branch of our business.

Apparatus.

It is perhaps in the character and form of the apparatus used to transmit messages that the greatest progress has been made. It is difficult to say whether increased business has led to better apparatus, or whether beautiful apparatus has led to large business. One thing is certain that the better the work is done the more is business encouraged, and work cannot possibly be well done if the apparatus used for discharging that business is inefficient or backward. When the Post Office assumed the control of the telegraphs, it amalgamated in to one department an incongruous combination of various systems, worked by differently trained staffs, due to the various companies having been formed at different periods to inaugurate different patents. The Electric Telegraph Company established the needle system of Cooke and Wheatstone, the printing system of Bain, which merged into that of Morse, and the various improvements patented by Varley; the Magnetic Company fathered the magnetic system of Henley and the bell system of Bright; the British Company introduced the system of Highton; the United Kingdom Company promoted the beautiful type-writer of Prof. Hughes; and the Universal Private Company was established to introduce the simple A B C system of Wheatstone.

We had telegraphs that appealed to the eye like the needle, those that appealed to the ear like the bell, some recorded signals in ink like the Morse, others printed their characters in bold type like the Hughes. Some were slow but simple like the A B C, others were fast but complicated like the automatic. Time and patience were needed to consolidate into homogeneity this heterogeneous collection of telegraphs and telegraphists. Some years elapsed before the doctrine of the survival of the fittest was asserted.

Now, in 1887, the predominant feature of our telegraphs is the simple sounder and the fast speed automatic recorder. Reading by sound is confined almost exclusively to the United Kingdom and to the United States. In Europe there is scarcely a sounder outside our islands. This is very remarkable for the sounder is simpler, more expeditious, and more accurate, than any other key system. Those who have been educated to regard a record as an element of accuracy can only be convinced by actual experience that it is an element of error, and this experience they will not seek. The argument they use against its adoption, viz., its liability to error is the very reverse of the fact.

Comparative Return, showing the Number and Description of Telegraph Instruments in the United Kingdom.

Year.	Automatic.	Sounders	Printers.	Needles.	Bells.	A B C's.	Miscellaneous.	Total.
1877...	164	1,294	1,692	3,680	210	4,572	129	11,741
1878...	167	1,380	1,560	3,495	277	4,641	859	12,376
1882...	224	2,000	1,330	3,791	313	4,398	2,035	14,091
1886...	384	3,181	1,368	4,003	388	3,883	5,179	18,386

During the past ten years a complete revolution has been effected in the quality and manufacture of our instruments. Exact measurement and scientific principles have supplanted rough and ready methods. Complete specification and rigid inspection have replaced cheap and nasty competition. The workmanship of a good telegraph instrument is to be rivalled only by that of a chronometer. Technical training has converted the workshop into a scientific laboratory.

The rapid increase of business that resulted from the uniform shilling tariff soon led to the erection of more wires, and the multiplication of wires soon attracted attention to methods of duplexing and quadruplexing the circuits. The duplex system means a mode of sending two messages in opposite directions at the same time. This was shown to be possible by Gintl, in Vienna, in 1853, but the necessity for such a system did not arrive until 1872, and as at the moment a want is felt something is sure to turn up to supply this want, so when duplexing was needed Mr. Stearns arrived from America with a well worked out practical system that was at once adopted, improved, and perfected. Still further congestion arising, quadruplex working, or the art of sending four messages on one wire at the same time, became desirable, and a practical quadruplex system, due to Mr. Edison, was imported in 1877 from the same inventive and practical region, the United States. Later on, in 1885, a still further development was matured in America, viz., the multiplex system of Delany, by which six messages can be simultaneously sent, which we have adopted, and the main features of which I now show you in action. The chief reason why these systems have been matured in America is that the want has been experienced there before here. Neither system was invented in America—each was invented in Europe. There are other wants that have been experienced here before there, and those who have visited the States have found that English inventions are equally appreciated and adopted there. It is in automatic telegraphy that we have made the greatest advances. The following table illustrates the progress made.

	Words per minute.	Speed to Ireland.
1870	80	50·3
1875	100	70
1880	200	150
1885	350	250
1887	450	450

Digitized by Google

This increase has been due not only to improvement in the design of the apparatus, but to the steady examination of every defect and its removal, in the instrument and on the line. It would require a paper of itself to narrate the ten years' conflict with electro-magnetic inertia, static induction, climatic influences, and battery defects. The table tells the result of this conflict, and the battle is not yet over; and diagram I. shows how scientific methods and improved apparatus have checked the rate of growth of wires, and have made cheap telegraphy possible. There still exists in our system a potentiality of expansion. We are now attacking the wires. Copper is replacing iron on our poles, with very advantageous results. Its better conductivity, and its entire freedom from electro-magnetic inertia, give it an immense superiority over iron. Its greater price per ton is compensated by its lesser weight per unit resistance.

We are also examining and testing various modes of laying wires underground, with a view to attaining greater speed of working, which hitherto has checked the establishment of underground work.

One consequence of the introduction of these advanced systems of working has been the necessity to educate the operating staff in the scientific and technical details of the business. The absence of technical knowledge in all branches has hitherto been a great difficulty to surmount. The technical examinations inaugurated by this society, and continued by the City and Guilds Institute, have been most beneficial, but the most successful incentive has been the selection and promotion of those who have given their attention to their own scientific education. This evident necessity for technical knowledge is reacting on the higher Post Office officials, and one finds all over the country a healthful spirit of inquiry arising—a striving after something better than the mere perfunctory discharge of official duties. There is something so captivating in the development of the practical applications of electricity, that those who make a study of it, especially experimentally, find in it more real enjoyment than any puzzling over the vagaries of the modern poet, or poring over the meaning of ancient cynics. A successful experiment is a distinct revelation—an admission into courts where, according to Bacon, are found "secrets not dangerous to know, sides and parties not factious to hold, precepts not penal to disobey."

(To be continued.)

PHYSICAL SOCIETY.—May 14.

Prof. W. E. AYRTON, Vice-President, in the chair.

Mr. T. Mather was elected a member of the society.

The following papers were read:—*On a Modification of a Method of Maxwell's for Measuring the Coefficients of Self-Induction*, by E. C. RIMINGTON. The method referred to is given in Maxwell's "Electricity and Magnetism," § 778, Vol. 2, and is called "Comparison of the electrostatic capacity of a condenser with the electro-magnetic capacity of a coil." The apparatus used consists of a Wheatstone bridge having the coil in one, and the condenser as a shunt to the opposite, arm. In order that no deflection may be produced, either for steady or unsteady currents, a troublesome double adjustment of the resistances is necessary, and to obviate this the modification was devised. It consists in placing the condenser as a shunt to only part of the arm, and this part can be varied by sliding contacts without altering the whole resistance of the arm. An ordinary resistance balance for steady currents is first obtained, and the sliders are then adjusted until no deflection is produced on breaking the battery circuit. Under these circumstances, it is shown that $L = Kr^2 \frac{D}{B}$, where K is the capacity of the condenser, r the resistance between the sliders, and D and B the resistances of the arms in which the coil and condenser are placed. The conditions of maximum sensibility are investigated, and also those under which a telephone may replace the galvanometer; in the latter it is shown that the only possible solution is when $r = B$, *i.e.*, Maxwell's arrangement. The author believes his modification would be made much more sensitive by adopting the "cumulative" method used by Profs. Ayrton and Perry in their secohmmeter, and in his case neither the speed nor the "lead" need be known. Mr. W. N. SHAW asked whether any serious difficulties were experienced with telephones, owing to electrostatic capacities of wires, &c., and Mr. W. E. SUMPNER pointed out that the particular arrangement given in Maxwell is not always the most positive, as was shown in his remarks at the last meeting of the Society of Telegraph-Engineers. Mr. BOSANQUET thought the method a valuable one, and hoped many experiments would be made on coils whose coefficients were calculable, in order to find out the differences between calculated and observed results. Prof. AYRTON referred to the recent paper by Prof. J. J. Thompson in the *Philosophical Transactions*, and pointed out that the formula there given for the capacity of a condenser in electromagnetic measure is identical with that given in Maxwell § 776, when the printer's error of interchanging a and α in the denominator for R_2 is corrected.

On a Magnetic Potentiometer, by A. P. CHATTOCK, read by Prof. REINOLD. The so-called magnetic resistance between two points on a magnetic circuit may be expressed as the ratio of the difference of potential to the total induction passing from one to the other (provided there be no magnetomotive force between them). From the fact that the volume integral of induction through a wire helix of constant cross section is proportional to the average difference of potential between its ends, it follows that any alteration in that difference of potential will give rise to an E.M.F. in the helix proportional to that alteration. Hence, if the wire be connected to a ballistic galvanometer, the combination may be called a magnetic potentiometer. A helix is formed by winding wire uniformly on a piece of solid indiarubber or canvas gas tubing of constant cross section, using an even number of layers to avoid external inductive effects, and leaving a small space between the turns, so as to allow the tube to bend without elongating. Experiments made to measure the difference of potential between the ends of a magnet gave satisfactory results. One end of the helix was held stationary at one end of the magnet, whilst the other was moved quickly to the other end of the magnet, and the resulting throw of the galvanometer observed. This was next done at two operations, and the sum of the two throws was very nearly equal to the first. The results can be reduced to absolute measure by passing the helix through a coil of n turns, bringing its ends together, and starting or stopping a current C in the coil, the resulting throw of the galvanometer being noticed. The magnetomotive force used in this experiment is $4\pi nC$. An interesting discussion followed, in which Prof. PERRY, Mr. SHAW, Prof. AYRTON, and Mr. BOSANQUET took part, the latter mentioning a measurement of magnetic potential made by himself some years ago. In consequence of the absence of Prof. S. P. Thompson, his paper on secondary generators was postponed till next meeting.

LEGAL.

Anglo-American Brush Company v. R. E. Crompton and Co.

This was an appeal from the order of Mr. Justice Kay directing a commission to the United States to take the evidence of Mr. C. F. Brush at the instance of the plaintiffs. We understand the appeal was in consequence of what the defendants considered to be insufficient affidavits on the part of the plaintiffs to justify a commission, but further affidavits having been filed stating further communications since the date of the order, the Court of Appeal declined to depart from the established practice in these cases and confirmed the order of Mr. Justice Kay.

COMPANIES' MEETINGS & REPORTS.

West India and Panama Telegraph Company (Limited).

The twentieth ordinary general meeting of the members of the West India and Panama Telegraph Company (incorporated 9th January, 1877) was held at Winchester House, 50, Old Broad-street, E C., on Wednesday, the 18th inst., under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the previous meeting, which the Chairman signed as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, this time last year we had to announce to you that there was a falling off in the traffic receipts of a little over £2,000 for the last half of the year 1885. This half year our traffic receipts are practically the same as they were at that time. I think telegraph receipts are (political disturbances set aside, and there are no political disturbances in the West Indies) a very good barometer of the state of trade in any region that the telegraph serves, and therefore we may deduce from the circumstance that our traffic receipts continue to be the same as they were this time last year, that the same depression in the sugar trade exists now as it did then; indeed, the prices ruling in the sugar market confirm this view. We find that sugar, which generally speaking used to be worth £1, is worth now only 11s. to 12s. per cwt., and I need not say that the sugar industry causes the chief source of our revenue. At the same time we have been very unfortunate in the matter of repairs, a circumstance which we cannot control. The movements of the sea, the earth, and the winds are beyond human control, and they affect our cables sometimes very prejudicially. This half year we have had twelve cables interrupted, while in the corresponding period of last year we had only ten interrupted. The length of cable used has been in excess of that required during the corresponding period of last year. We had one very long piece repaired in the Jamaica-Colon section after prolonged and costly operations, owing to the great depth of water in which it lay. As stated in the report, the cable was recovered finally at a depth of 1,613 fathoms. The ship was engaged on that repair for three months, from the end of September to the end of December. The history of that cable is interesting because when the contractors laid it originally it failed. I think they were about three years in repairing it, notwithstanding all their appliances and the three ships that were sent out, and what was the sum it cost them we never knew. This repair of ours cost us £5,000, which makes a very serious hole in the small revenue which we enjoy. The expenditure on cable repairs this half year has made it important that we should draw on our stock, for which we had already contracted, and which has been hitherto lying with our contractors. After completing that work our ship had to go to resume the repairing of another break on the Jamaica-Porto-Rico section, but had to be recalled in order to proceed with other repairs on the Holland Bay-Ponce cable; but she is now on her way to England, and I hope she will be here in about 10 days from now, to take up the 250 knots of cable referred to in the last report, and will proceed to the West Indies to complete the repair of the original Jamaica-Porto-Rico cable. With regard to the ordinary expenses, over which we may be assumed to have some control, they offer no feature for any remark. There is no variation in them from former years. Coming to the issue of debentures, I am glad to say that we have

Digitized by Google

speed, say N′, and measure the apparent increase of resistance of the coil, say σ', above its original value.

Then if $\frac{\sigma}{N} = \frac{\sigma'}{N'}$, the apparent increase of resistance obtained with either speed may be used, and the required coefficient of self-induction $= K\frac{\sigma}{N}$; if, on the other hand, $\frac{\sigma}{N}$ is larger than $\frac{\sigma'}{N'}$, then the speed N′ is too high, and possibly also is N, to give accurate results. Therefore use a speed N″ lower then N, and measure the new increase of resistance σ''.

If now $\frac{\sigma}{N} = \frac{\sigma''}{N''}$ the speed N was not too high to give accurate results, although N′ was; hence the apparent increase of resistance obtained with either speed N or N″ may be used, and the required coefficient of self-induction $= K\frac{\sigma}{N}$.

If $\frac{\sigma}{N}$ be only a little *greater* than $\frac{\sigma'}{N'}$ and if N′ *much exceeds* N, then it will not be necessary to make a third experiment at the lower speed N″ unless very accurate results are desired, for the coefficient of self-induction can only be a very little greater than $K\frac{\sigma}{N}$, which may therefore be practically taken as the correct value.

By the simple addition, therefore, of such a commutating arrangement as we have described to an ordinary Wheatstone bridge, it becomes possible, whenever the resistance of a coil electro-magnet, &c., is being measured, to measure also the coefficient of self-induction in absolute measure, by a zero method which is as sensitive for the measurement of self-induction as the ordinary Wheatstone bridge method is for the measurement of resistance.

From what precedes it follows that

$$L = K\frac{\sigma - \sigma''}{N - N''};$$

so that if s_1, s_2 be the apparent resistanees of the coil at two speeds, N_1, N_2 revolutions per minute, the speeds not being too large,

$$L = K\frac{s_1 - s_2}{N_1 - N_2};$$

hence *the coefficient of self-induction can be determined from two experiments made with the revolving double commutator without knowing the true resistance of the coil at all.*

If there be doubt as to whether the speeds N_1 and N_2 are too large, a third check speed, N_3, may be used; or instead, as explained in Appendix II., a rough test of the resistance of the coil for steady currents may be made; but time need not be spent in obtaining an accurate balance, as quite a rough balance can be used as follows:—Let O on the scale be the true zero for no current passing through the galvanometer, and let the spot of light be at, say, 156 divisions when an approximation is made to balance for steady currents, the resistance of the coil appearing to be s ohms, then the zero to be used in making the *second* and *third* tests just described is $l \times 156$, where l is the lead and σ is to be reckoned as the increase above the approximate value of the resistance for steady currents.

Commercial Forms of the Instrument.

The long-range instrument previously described requires an electromotor to drive it, and a speed-indicator to register its speed, hence it would be too cumbersome for everyday work. Further, as it is very difficult to maintain the absolute constancy of the speed of a small motor driving a friction brake, like our commutating arrangement, at a high-speed for any considerable time, in consequence of very slight variations in the friction of a high-speed brake producing marked variations in the speed, it requires two experimenters to use the form of our instruments already described; one to vary the resistance until the galvanometer needle comes to zero, and the other to note the speed of the motor at the moment that the first experimenter gives a signal that the galvanometer needle is at zero.

Hence, in the autumn of last year, we were led to consider what form should be given to the commercial instrument to be used for the measurement of self-induction in this way. The main condition of the problem was that the instrument should be able to be used by one experimenter *alone*, since one experimenter alone can measure a resistance with a Wheatstone bridge, and therefore we felt that if another experimenter had to be summoned when a coefficient of self-induction had to be measured, the instrument would lose much of its practical value. Our first idea was to employ clockwork that would drive the commutating arrangement at various fixed speeds, determined by the adjustment of a certain powerful governing arrangement, and to this end commutators of very small diameter were constructed, so as to waste only a small amount of power in friction and interfere but little with the action of the governor. The problem at first sight appeared an easy one, but the experiments of one of our assistants, Mr. Bourne, whom we have to thank for the many ingenious devices that he has suggested, and for the skill that he has brought to bear in the construction of the various experimental forms that the apparatus has passed through in its development, showed that in consequence of the high speed of the commutator, and of its acting as a friction brake, good results could only be obtained with clockwork of such unwieldy dimensions as to make it impossible for the instrument to be made portable; further, it was contrary to our engineering instincts to employ an apparatus which wasted so large a portion of the power required to drive it in the governing arrangements.

When making the experiments with the original commutating apparatus, two methods suggested themselves of obtaining a balance—the one, to try and to keep the speed of the electro-motor nearly constant, and to vary the resistance of one of the arms of the bridge, by trial, until the galvanometer needle came to zero; the other, to commence by increasing one of the arms of the bridge by a definite amount, and to vary the speed of the electro-motor, by trial, until the galvanometer needle came to zero; and it soon appeared that the second method was the one that would have to be adopted in a practical instrument, since, while it is very difficult to maintain a constant speed, there is no difficulty in obtaining a gradually diminishing or increasing speed. For example, the apparatus may be provided with a fly-wheel having a large amount of inertia, and may be driven by hand more or less fast until the galvanometer needle comes to zero. The next step in order to avoid the necessity of a second experimenter was to devise a *recording speed-indicator*, and the best form that we have arrived at is based on the principle that we employed in constructing an apparatus some years ago for experiments on centrifugal force, described at a meeting of the Physical Society at the time, and in regular use in the mechanical laboratory of the Finsbury Telegraph College ever since, for experiments on centrifugal force.

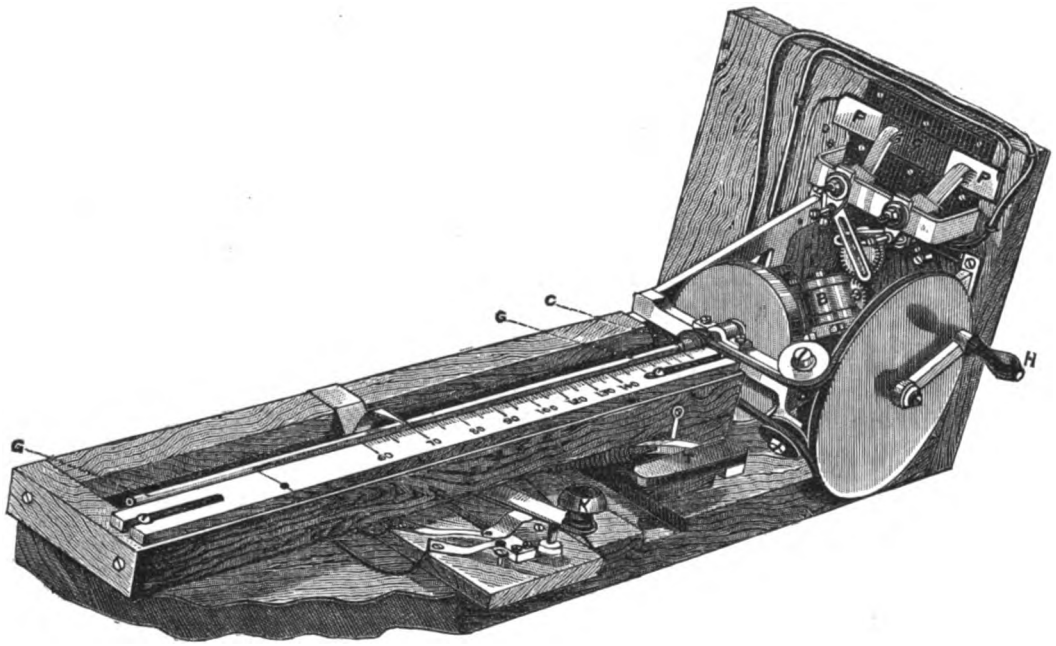

Fig. 5.—Experimental Secohmmeter.

Attached to the commutation of our self-induction apparatus is a box, B (Fig. 5), fitted with weighted elastic sides made of corrugated steel, which fly out more and more under the action of centrifugal force, as the box is rotated faster and faster. A stout glass tube, G, of comparatively small bore, open at both ends, is cemented into a collar in the axis of the box, and rotates with the box. The box is completely filled with mercury, and the tube partially, hence the volume of the box expands as its sides fly out and the length of the column of mercury in the tube diminishes, so that the length of the column at any moment is a measure of the speed of rotation of the box. In the neck of the collar, C, in which the tube is cemented, there is a steel tap attached to an axial spindle passing through a tube inside the box, and projected out of this tube at the other end of the box. If this spindle be turned relatively to the box, the

Digitized by Google

tap is opened or closed. At the commencement of an experiment the tap is opened, and the handle H is turned with the right hand, faster and faster, until, on depressing the key K with the left hand from time to time, the galvanometer needle is seen to be approaching zero, or the spot of light the zero position on the scale. The key may now be kept depressed, and on turning the handle a little faster a speed is at length reached producing exact balance—if the handle be turned faster, the needle or spot of light deflects to one side of the zero, if more slowly to the other—at this moment the trigger T is lightly touched with the left hand and a spring is liberated. This has the effect of producing a resistance to the rotation of the tap-spindle, which previously was rotating freely with the rotating box, and the tap is thus turned off, cutting off the connection between the mercury in the glass tube and that in the box. Consequently the mercury in the tube remains, even after the instrument is stopped, of exactly the same length that it had when the trigger was touched. *The position of the end of thread of mercury in the tube is now read off on the scale attached, and the apparent increase of resistance of the coil, electro-magnet, or whatever it may be, divided by the number on the scale, gives the required coefficient of self-induction in second-ohms without any further calculation.*

The instrument is therefore *direct reading.*

This first form of recording speed-indicator was designed to be used vertically, as may be seen from the figure, but we soon found that great advantages were to be gained by placing it *horizontal*. If the glass tube be vertical the mercury in the tube exerts a pressure on the elastic sides of the box, which diminishes as the mercury falls on the speed of rotation being increased. This diminution of pressure causes the mercury not to fall so much for a given speed as it would were there no variation in the pressure due to the mercury in the tube, and so it diminishes the sensibility, hence we have been led to employ a horizontal tube. Further, since the mercury in a horizontal tube exerts no pressure on the elastic sides of the box, the amount of mercury in the tube does not in any way affect the sensibility, provided that the scale is so placed that the zero is opposite the end of the thread of mercury when the box is at rest. Hence, should any spilling of the mercury by accident occur when the instrument is moved about, the accuracy of the readings is not altered, so that by placing the tube horizontal we obtain greater sensibility and constancy in the readings.

Variations in the temperature from day to day cause alterations in the volume of the mercury, and so alter the length of the thread of mercury in the tube, but this also introduces no error in the experimental result, nor difficulty in using the instrument, since before the commencement of the experiment the scale is slightly moved until the zero on it comes opposite the position occupied by the end of the thread of mercury on the day in question when the box is at rest.

At first, rotating commutators similar to those shown in Fig. 1 were employed with the apparatus shown in Fig. 5; next the brushes were made of a variety of different forms, so as to press *radially* on the rotating commutators to prevent the wear altering the lead, and thus changing the sensibility of the instrument; but this form of commutator has at length been entirely superseded by the two oscillating arms, or brushes, A, A, worked by a cam. Each arm is composed of several pieces of hard copper, contact being made through the ends, as in many of the switches now used for electric light work. The end of each brush alternately rubs on a flat piece of phosphor bronze, P, P, when it makes contact, and on a *flat* piece of glass or agate, *g*, when it does not. This form of commutator we found superior for our purpose to the double cylindrical one, since, with the two oscillating arms, the lead can be more easily varied for adjustment; and this slight adjustment of the lead, we may here mention, forms the fine adjustment in the construction of this direct reading instrument. Further, the slow wearing of this form of brush does not alter the lead, consequently the value of the graduations of the scale remains constant.

The lead aimed at in the construction of these instruments is $\frac{1}{4}$, as that gives an equal time to each operation, but in any actual instrument it may be made a little more or less than $\frac{1}{4}$, being slightly altered, as just explained, in the final adjusting of the instrument by the maker.

It might appear, at first sight, that the two ends of an oscillating lever, or the two prongs of a vibrating tuning fork, would perform the required makes and breaks in the right order, but a reference to the cycle of operations given in the table, page 18, and a little consideration will show that the two prongs of a tuning fork cannot perform the required cycle of operations in the correct order.

Following the precedent of naming an instrument after the name of the unit employed—for example, "ammeter," "voltmeter," "ohmmeter," "wattmeter"—it seems desirable to call this instrument after the name of the commercial unit of self and mutual induction. The absolute electromagnetic unit of self and mutual induction is one centimetre, a name used by all scientific nations. But the commercial unit of self and mutual induction is $99,777 \times 10^4$ centimetres, or second-ohm, which is a little less than 10^9 centimetres, or one earth's quadrant. Now, in spite of the difference between these two numbers, which, although small, it is a pity to lose sight of, the English word "quadrant" is not used in French, therefore it would not be well to suggest this word as the international name for the unit. Yet it is most important that some name should be universally adopted, since the use of simple familiar names has much to do with making people familiar with the laws of the effect measured by the unit. The unit of electrostatic capacity, the farad, has been called after the greatest experimental worker in electricity; it would, therefore, seem appropriate that the unit of electromagnetic capacity should be called after Maxwell, the greatest mathematical worker in electricity. We do not, however, like to propose this, as we feel there might be difficulty in obtaining the general acceptance of the name of an Englishman, however great, unless it were sanctioned by an international electrical congress, or unless the man's name was intimately associated in men's minds with self and mutual induction. And Maxwell's large contribution to the subject of electromagnetic induction is surrounded by his equally large contributions to all other branches of electricity and magnetism—a giant surrounded by giants is not prominent. Coming to the last two years, we are glad that the leader and all those who have followed him in taking part in the widening of our ideas in self-induction are still with us. Hence we are driven to suggesting a temporary name for the unit, and as the first three letters in "second" are common to the name in English, French, German, Italian, &c., and ohm is also common, we venture to suggest "*secohm*" as a provisional name, and our instrument we will therefore call a "*secohmmeter.*"

(To be continued.)

FIFTY YEARS' PROGRESS IN TELEGRAPHY.*

By W. H. Preece, F.R.S., Vice-President of the Society.

This is the Jubilee year of the electric telegraph in England. On July the 25th, 1837, the first practical trial of telegraphy was made between Euston and Camden, on the London and North-Western Railway, by Cooke and Wheatstone. Nine tedious years were spent in endeavouring to create enthusiasm among financial circles for this young and novel means of communication. The first company formed to develop the business of transmitting and delivering written telegrams was incorporated in 1846, and was called the Electric Telegraph Company. Wires were speedily extended to every great centre of trade along the great railways that were then being developed, and about 1851 the business was fairly established. Telegraphy and railways have grown up side by side. In 1851 submarine telegraphy was proved to be practical. Cables were laid in 1852 and 1853 to France, Belgium, Holland, and Ireland, and from that year domestic and international telegraphy grew and prospered. The Electric Telegraph Company suffered the fate of all prosperous initiators of that which is novel, useful, and successful. The validity of their patents was contested, the strength of their business was assailed all along the line by enterprising competitors. Their monopoly was broken, but the public gained by this active rivalry greater development of communication and considerable reduction of rates. We see the same process going on at the present day with respect to telephones, but with less success.

The rates for messages, which were as high as 12s. 6d. for twenty words, were based on a sliding scale. The rates for a message of twenty words were fixed at 1d. per mile for distances under 50 miles, then ½d. per mile up to 100 miles, and ¼d. per mile for a distance of more than 100 miles; addresses forming part of the twenty words. A message to Glasgow cost 8¾d. per word, to Manchester 5$\frac{1}{20}$d.

Various reductions took place from time to time. In 1864, that is in less than twenty years, three great companies competed in every principal town for this profitable business of telegraphy. The United Kingdom Telegraph Company was formed in 1861 to introduce the universal shilling rate; but the severity of the competition of their opponents was too great for this spirited company, and they had, in 1865, to submit to the following general tariff:—Within London and other towns, 6d.; within 100 miles, 1s.; within 200 miles, 1s. 6d.; over 200 miles, 2s.—addresses being sent free.

The public now began to suffer. Only the larger towns, where profitable business could be tapped, were served. The smaller towns were neglected, and great villages had to suffer the aggravation of seeing posts and wires pass through their main thoroughfares without being able to avail themselves of this speedy mode of communication.

Telegraphy became a necessity of the age for the due and proper transaction of business. It became so closely allied with other modes of communication that public opinion, in 1868-9, forced the Government to purchase and absorb all the telegraph companies, and to transfer their business to the care of the Post Office, which had shown itself so capable in dealing with letters and newspapers, and in establishing the penny post.

The telegraphs of this country again became a great monopoly; but there is a vast difference between a monopoly in the hands of a private speculative corporation, subject to no control but that of its own closed ring, and whose sole object is to earn dividends or to make money, and that in the hands of the Government, whose sole object is to serve their masters, the public, faithfully and well, and whose actions are incessantly supervised by the jealous and watchful eyes of those they serve, who have an equally watchful and much less tolerant press in which to air their wrath and grievances, and an active House of Parliament ever ready to counteract and reform real abuses when fairly and properly laid before it.

It is impossible to conceive supervision more complete than that to which the Post Office is subject. The receiver of every letter, the transmitter of every message, the editor of every paper, the reader of every news despatch, every householder or business man, can see for himself how his own business is conducted; he can growl and grumble to his heart's content at any error or delay that may occur, with a certain knowledge that his complaint has been heard, and, if just, remedied, although he may not always be satisfied with the attention he receives. The telegraphic business of this country has reached its present dimensions because the work has been done well, and it has been done well because the mode of doing the business has been so well and so thoroughly supervised by the public.

The transfer of the telegraphs to the State took place on February 5th, 1870. The tariff established by Parliament was a uniform tariff of 1s. for twenty words, addresses being sent free, and this tariff remained in force until October 1st, 1885, when the present simple word tariff of ½d. per word, irrespective of distance, and including addresses, with a minimum of 6d., was introduced.

The average cost for the transmission of a telegram immediately before the transfer was 2s. 1¼d. After the transfer it was reduced to 1s. 1d. It is now 8d.

* Paper read before the Society of Arts, on Wednesday, May 18.

Digitized by Google

The number of offices open to the public prior to the transfer was 2,932, but owing to the existence of three large companies in the same town, the number of towns in telegraphic communication was probably not more than 2 500. There are now 6,514 offices open to the public. [See Appendix I.]

But the amount of business done is a better criterion of the benefits that the public have derived from the transfer of the telegraphs to the Post Office. At the close of the year 1870 the gross receipts of the Telegraph Department were £612,301; at the close of 1886 they were £1,787,264, and at the close of this year they will probably reach £1,950,000. The number of messages transmitted in 1869 were 6,000,000; in 1870 they were 9,850,177; in 1880 they were 26,547,137; in 1886 they were 39,235,813; and at the end of this year (1887) they will probably exceed 52,000,000. [*Vide* Appendix II.] Diagram I. exhibits graphically the rate of growth of messages and wires, and it illustrates pointedly the result of the ½d. per word tariff, whose success has exceeded all estimate and anticipation.

The development of telegraphy is better shown in our great central station than anywhere else. The following Table is interesting:—

Date.	One day's messages.	Instruments.	Staff.		
			Male.	Female.	Total.
Before transfer..	8,500	...	...	...	...
1870.....	12,000	350	280	485	765
1880.....	43,000	486	826	598	1,424
1886.....	98,570	945	1,490	802	2,292

The number of messages dealt with each day ranges from 70,000 to 100,000, nearly half of which are transmitted messages which have to be both received and forwarded, and therefore become, practically, two messages, although they count as only one in the total.

The local traffic in London—that is, messages emanating from one part of London for delivery in some other part, and passing through the central station—is very large. It ranges from 12,000 to 18,000 messages per day. In 1868 there were 60 offices open in the metropolis, dealing with 300 messages per day; there are now 480 offices, dealing with an average of 15,000 messages a day.

The total number of local metropolitan messages for four weeks was:—February, 1870, 138,534; January, 1880, 726,199; January, 1887, 1,277,838—a tenfold growth nearly.

Press Arrangements.

One of the great objections raised against the absorption of the telegraphs by the State was the difficulty which the Government would have in transmitting news. In no country is there now such a complete system of telegraphy for news purposes as there is in the United Kingdom. Two complete news circuits serve always (day and night) the following important centres from London:—

1. Newcastle, Edinburgh, Glasgow, Dundee, Aberdeen.
2. Nottingham, Sheffield, Leeds, Bradford.
3. Birmingham, Manchester, Liverpool.
4. Bristol, Gloucester, Newport, Cardiff, Exeter, Plymouth.
5. Brighton, Portsmouth.
6. Dublin, Cork, Belfast.
7. Northampton, Leicester, Derby.

There are several other groups in the provinces served from these centres, and every evening after six p.m. a third, and frequently, especially in the Parliamentary Session, a fourth circuit is made up to all these stations from London. Each office on each of these groups receives simultaneously the news sent from London. Thirty newspapers obtain the use of special wires, with clerks' services, from 6 p.m. to 6 a.m., many, like the *Scotsman*, the *Newcastle Chronicle*, and the *Manchester Guardian*, having two circuits; and whenever any great political event arises, such as the delivery of a great speech, all the important towns throughout the kingdom receive simultaneously a *verbatim* report of the speech. There is not a town in the country where a daily paper is printed which is not placed, after 6 p.m., in direct communication with London, and which does not deposit on every subscriber's breakfast table a nearly *verbatim* report of the previous night's debate in Parliament.

The press rates are very low. The average price paid is a little in excess of 2d. per 100 words. This entails a loss to the department roughly estimated at £200,000 a year, which is the amount the public is taxed for the support of the press. It is doubtful whether Parliament knew when it passed this low rate that it virtually meant a subsidy to the press. The loss might be very materially diminished if there were less competition and more union among newspapers and news agencies. As it is, the same matter has frequently to be sent twice over the same route, and the amount of unnecessary news sent, and therefore unnecessary expense incurred, is enormous, much of it finding its way into the waste paper basket. The supply of news before the transfer was very meagre. Reuter's telegrams, Parliamentary reports, general news, markets, races, were supplied for £200 a year. The companies did this jointly, and news was collected as well as distributed; but the Post Office is simply a carrier. It is not allowed to collect, and it has thus saved much of the obloquy that attached to the irresponsible monopoly of the telegraph companies. The average number of words supplied to each newspaper was said to be 4,000 a day. It is now roughly estimated at about an average of 12,000 in the recess, and 15,000 or 20,000 in the session.

The following will give some idea of the total number of words sent on one evening, on important political occasions, from the central station:—

April 8th, 1886.—Mr. Gladstone's Home Rule Bill, 1,050,500 words.

April 16th, 1886.—Land Purchase Bill, 841,500 words.

June 7th, 1886.—Irish Government Bill (Division), 863,700.

Appendix III. shows how rapid and great has been the increase in this branch of our business.

Apparatus.

It is perhaps in the character and form of the apparatus used to transmit messages that the greatest progress has been made. It is difficult to say whether increased business has led to better apparatus, or whether beautiful apparatus has led to large business. One thing is certain that the better the work is done the more is business encouraged, and work cannot possibly be well done if the apparatus used for discharging that business is inefficient or backward. When the Post Office assumed the control of the telegraphs, it amalgamated in to one department an incongruous combination of various systems, worked by differently trained staffs, due to the various companies having been formed at different periods to inaugurate different patents. The Electric Telegraph Company established the needle system of Cooke and Wheatstone, the printing system of Bain, which merged into that of Morse, and the various improvements patented by Varley; the Magnetic Company fathered the magnetic system of Henley and the bell system of Bright; the British Company introduced the system of Highton; the United Kingdom Company promoted the beautiful type-writer of Prof. Hughes; and the Universal Private Company was established to introduce the simple A B C system of Wheatstone.

We had telegraphs that appealed to the eye like the needle, those that appealed to the ear like the bell, some recorded signals in ink like the Morse, others printed their characters in bold type like the Hughes. Some were slow but simple like the A B C, others were fast but complicated like the automatic. Time and patience were needed to consolidate into homogeneity this heterogeneous collection of telegraphs and telegraphists. Some years elapsed before the doctrine of the survival of the fittest was asserted.

Now, in 1887, the predominant feature of our telegraphs is the simple sounder and the fast speed automatic recorder. Reading by sound is confined almost exclusively to the United Kingdom and to the United States. In Europe there is scarcely a sounder outside our islands. This is very remarkable for the sounder is simpler, more expeditious, and more accurate, than any other key system. Those who have been educated to regard a record as an element of accuracy can only be convinced by actual experience that it is an element of error, and this experience they will not seek. The argument they use against its adoption, viz., its liability to error is the very reverse of the fact.

Comparative Return, showing the Number and Description of Telegraph Instruments in the United Kingdom.

Year.	Automatic.	Sounders	Printers.	Needles.	Bells.	A B C's.	Miscellaneous.	Total.
1877...	164	1,294	1,692	3,680	210	4,572	129	11,741
1878...	167	1,380	1,560	3,495	277	4,641	859	12,376
1882...	224	2,000	1,330	3,791	313	4,398	2,035	14,091
1886...	384	3,181	1,368	4,003	388	3,883	5,179	18,386

During the past ten years a complete revolution has been effected in the quality and manufacture of our instruments. Exact measurement and scientific principles have supplanted rough and ready methods. Complete specification and rigid inspection have replaced cheap and nasty competition. The workmanship of a good telegraph instrument is to be rivalled only by that of a chronometer. Technical training has converted the workshop into a scientific laboratory.

The rapid increase of business that resulted from the uniform shilling tariff soon led to the erection of more wires, and the multiplication of wires soon attracted attention to methods of duplexing and quadruplexing the circuits. The duplex system means a mode of sending two messages in opposite directions at the same time. This was shown to be possible by Gintl, in Vienna, in 1853, but the necessity for such a system did not arrive until 1872, and as at the moment a want is felt something is sure to turn up to supply this want, so when duplexing was needed Mr. Stearns arrived from America with a well worked out practical system that was at once adopted, improved, and perfected. Still further congestion arising, quadruplex working, or the art of sending four messages on one wire at the same time, became desirable, and a practical quadruplex system, due to Mr. Edison, was imported in 1877 from the same inventive and practical region, the United States. Later on, in 1885, a still further development was matured in America, viz., the multiplex system of Delany, by which six messages can be simultaneously sent, which we have adopted, and the main features of which I now show you in action. The chief reason why these systems have been matured in America is that the want has been experienced there before here. Neither system was invented in America—each was invented in Europe. There are other wants that have been experienced here before there, and those who have visited the States have found that English inventions are equally appreciated and adopted there. It is in automatic telegraphy that we have made the greatest advances. The following table illustrates the progress made.

	Words per minute.	Speed to Ireland.
1870	80	50·3
1875	100	70
1880	200	150
1885	350	250
1887	450	450

Digitized by Google

This increase has been due not only to improvement in the design of the apparatus, but to the steady examination of every defect and its removal, in the instrument and on the line. It would require a paper of itself to narrate the ten years' conflict with electro-magnetic inertia, static induction, climatic influences, and battery defects. The table tells the result of this conflict, and the battle is not yet over; and diagram I. shows how scientific methods and improved apparatus have checked the rate of growth of wires, and have made cheap telegraphy possible. There still exists in our system a potentiality of expansion. We are now attacking the wires. Copper is replacing iron on our poles, with very advantageous results. Its better conductivity, and its entire freedom from electro-magnetic inertia, give it an immense superiority over iron. Its greater price per ton is compensated by its lesser weight per unit resistance.

We are also examining and testing various modes of laying wires underground, with a view to attaining greater speed of working, which hitherto has checked the establishment of underground work.

One consequence of the introduction of these advanced systems of working has been the necessity to educate the operating staff in the scientific and technical details of the business. The absence of technical knowledge in all branches has hitherto been a great difficulty to surmount. The technical examinations inaugurated by this society, and continued by the City and Guilds Institute, have been most beneficial, but the most successful incentive has been the selection and promotion of those who have given their attention to their own scientific education. This evident necessity for technical knowledge is reacting on the higher Post Office officials, and one finds all over the country a healthful spirit of inquiry arising—a striving after something better than the mere perfunctory discharge of official duties. There is something so captivating in the development of the practical applications of electricity, that those who make a study of it, especially experimentally, find in it more real enjoyment than any puzzling over the vagaries of the modern poet, or poring over the meaning of ancient cynics. A successful experiment is a distinct revelation—an admission into courts where, according to Bacon, are found "secrets not dangerous to know, sides and parties not factious to hold, precepts not penal to disobey."

(To be continued.)

PHYSICAL SOCIETY.—May 14.

Prof. W. E. AYRTON, Vice-President, in the chair.

Mr. T. Mather was elected a member of the society.

The following papers were read:—*On a Modification of a Method of Maxwell's for Measuring the Coefficients of Self-Induction*, by E. C. RIMINGTON. The method referred to is given in Maxwell's "Electricity and Magnetism," § 778, Vol. 2, and is called "Comparison of the electrostatic capacity of a condenser with the electro-magnetic capacity of a coil." The apparatus used consists of a Wheatstone bridge having the coil in one, and the condenser as a shunt to the opposite, arm. In order that no deflection may be produced, either for steady or unsteady currents, a troublesome double adjustment of the resistances is necessary, and to obviate this the modification was devised. It consists in placing the condenser as a shunt to only part of the arm, and this part can be varied by sliding contacts without altering the whole resistance of the arm. An ordinary resistance balance for steady currents is first obtained, and the sliders are then adjusted until no deflection is produced on breaking the battery circuit. Under these circumstances, it is shown that $L = K r^2 \frac{D}{B}$, where K is the capacity of the condenser, r the resistance between the sliders, and D and B the resistances of the arms in which the coil and condenser are placed. The conditions of maximum sensibility are investigated, and also those under which a telephone may replace the galvanometer; in the latter it is shown that the only possible solution is when $r = B$, *i.e.*, Maxwell's arrangement. The author believes his modification would be made much more sensitive by adopting the "cumulative" method used by Profs. Ayrton and Perry in their secohmmeter, and in his case neither the speed nor the "lead" need be known. Mr. W. N. SHAW asked whether any serious difficulties were experienced with telephones, owing to electrostatic capacities of wires. &c., and Mr. W. E. SUMPNER pointed out that the particular arrangement given in Maxwell is not always the most positive, as was shown in his remarks at the last meeting of the Society of Telegraph-Engineers. Mr. BOSANQUET thought the method a valuable one, and hoped many experiments would be made on coils whose coefficients were calculable, in order to find out the differences between calculated and observed results. Prof. AYRTON referred to the recent paper by Prof. J. J. Thompson in the *Philosophical Transactions*, and pointed out that the formula there given for the capacity of a condenser in electromagnetic measure is identical with that given in Maxwell § 776, when the printer's error of interchanging a and a in the denominator for R_2 is corrected.

On a Magnetic Potentiometer, by A. P. CHATTICK, read by Prof. REINOLD. The so-called magnetic resistance between two points on a magnetic circuit may be expressed as the ratio of the difference of potential to the total induction passing from one to the other (provided there be no magnetomotive force between them). From the fact that the volume integral of induction through a wire helix of constant cross section is proportional to the average difference of potential between its ends, it follows that any alteration in that difference of potential will give rise to an E.M.F. in the helix proportional to that alteration. Hence, if the wire be connected to a ballistic galvanometer, the combination may be called a magnetic potentiometer. A helix is formed by winding wire uniformly on a piece of solid indiarubber or canvas gas tubing of constant cross section, using an even number of layers to avoid external inductive effects, and leaving a small space between the turns, so as to allow the tube to bend without elongating. Experiments made to measure the difference of potential between the ends of a magnet gave satisfactory results. One end of the helix was held stationary at one end of the magnet, whilst the other was moved quickly to the other end of the magnet, and the resulting throw of the galvanometer observed. This was next done at two operations, and the sum of the two throws was very nearly equal to the first. The results can be reduced to absolute measure by passing the helix through a coil of n turns, bringing its ends together, and starting or stopping a current C in the coil, the resulting throw of the galvanometer being noticed. The magnetomotive force used in this experiment is $4\pi n C$. An interesting discussion followed, in which Prof. PERRY, Mr. SHAW, Prof. AYRTON, and Mr. BOSANQUET took part, the latter mentioning a measurement of magnetic potential made by himself some years ago. In consequence of the absence of Prof. S. P. Thompson, his paper on secondary generators was postponed till next meeting.

LEGAL.

Anglo-American Brush Company v. R. E. Crompton and Co.

This was an appeal from the order of Mr. Justice Kay directing a commission to the United States to take the evidence of Mr. C. F. Brush at the instance of the plaintiffs. We understand the appeal was in consequence of what the defendants considered to be insufficient affidavits on the part of the plaintiffs to justify a commission, but further affidavits having been filed stating further communications since the date of the order, the Court of Appeal declined to depart from the established practice in these cases and confirmed the order of Mr. Justice Kay.

COMPANIES' MEETINGS & REPORTS.

West India and Panama Telegraph Company (Limited).

The twentieth ordinary general meeting of the members of the West India and Panama Telegraph Company (incorporated 9th January, 1877) was held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 18th inst., under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the previous meeting, which the Chairman signed as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, this time last year we had to announce to you that there was a falling off in the traffic receipts of a little over £2,000 for the last half of the year 1885. This half year our traffic receipts are practically the same as they were at that time. I think telegraph receipts are (political disturbances set aside, and there are no political disturbances in the West Indies) a very good barometer of the state of trade in any region that the telegraph serves, and therefore we may deduce from the circumstance that our traffic receipts continue to be the same as they were this time last year, that the same depression in the sugar trade exists now as it did then; indeed, the prices ruling in the sugar market confirm this view. We find that sugar, which generally speaking used to be worth £1, is worth now only 11s. to 12s. per cwt., and I need not say that the sugar industry causes the chief source of our revenue. At the same time we have been very unfortunate in the matter of repairs, a circumstance which we cannot control. The movements of the sea, the earth, and the winds are beyond human control, and they affect our cables sometimes very prejudicially. This half year we have had twelve cables interrupted, while in the corresponding period of last year we had only ten interrupted. The length of cable used has been in excess of that required during the corresponding period of last year. We had one very long piece repaired in the Jamaica-Colon section after prolonged and costly operations, owing to the great depth of water in which it lay. As stated in the report, the cable was recovered finally at a depth of 1,613 fathoms. The ship was engaged on that repair for three months, from the end of September to the end of December. The history of that cable is interesting because when the contractors laid it originally it failed. I think they were about three years in repairing it, notwithstanding all their appliances and the three ships that were sent out, and what was the sum it cost them we never knew. This repair of ours cost us £5,000, which makes a very serious hole in the small revenue which we enjoy. The expenditure on cable repairs this half year has made it important that we should draw on our stock, for which we had already contracted, and which has been hitherto lying with our contractors. After completing that work our ship had to go to resume the repairing of another break on the Jamaica-Porto-Rico section, but had to be recalled in order to proceed with other repairs on the Holland Bay-Ponce cable; but she is now on her way to England, and I hope she will be here in about 10 days from now, to take up the 250 knots of cable referred to in the last report, and will proceed to the West Indies to complete the repair of the original Jamaica-Porto-Rico cable. With regard to the ordinary expenses, over which we may be assumed to have some control, they offer no feature for any remark. There is no variation in them from former years. Coming to the issue of debentures, I am glad to say that we have

Digitized by Google

had offers to take up the whole of those that are unissued. When we first issued those debentures the market was in rather an unfavourable position. Money was tight at the beginning of the year, and our shareholders did not come forward in the way that we expected; but we made a very satisfactory arrangement with our bankers, and have been borrowing the money to make up the deficiency of £12,000 at the bank rate, which has fallen to a low figure now, being only 2 per cent., so that in fact we have made a good thing by these debentures not being taken up. By placing these debentures at 5 per cent. there will be a saving of £500 a year to the Company. The fifth paragraph of the report refers to a scheme which has given us some anxiety and trouble, namely, the proposal of the French Government to connect the Brazils with North America, touching their West India colonies, Martinique and Guadeloupe. I want to ask what on earth can France want by going to the other side of the world to connect two points with a cable where she has no very great interest? It puzzled us enormously when the project was first mooted. The matter was discussed in the Chamber of Deputies on two or three occasions, and it seemed to us a ridiculous thing that the French Minister of Posts and Telegraphs should seriously debate the question, and ask the Chamber to give a grant of £40,000 to any telegraph company for the construction of such a cable. Fancy what would have been the result if our Secretary of State for the Colonies had asked for £40,000 a year for a similar purpose. I think that the scheme has fallen through for the present, and I hope it will not again be entertained. I think a great many of the members saw that they really had no call to spend £40,000 a year on connecting the very small colonies that they had got there, more especially since two of the most important of them are already served by the existing company, and the traffic from them is quite insignificant. I do not know that I have anything more to say to you; but I shall be very glad to answer any questions that shareholders may like to ask. Our future depends very much upon the condition of the West Indies. We cannot control Governments or the forces that are under the earth. They can both affect us prejudicially. When a Government subsidises sugar production anywhere it can do an enormous injury to other sugar-producing colonies. But it is not our business or within our power to alter such a condition of affairs as that. Then, again, the forces under the earth are the cause of the great loss that we have sustained in the category of expenditure, and I cannot hold out any hopes, seeing the region in which our cables are laid, that we may not again be the victims of the violence of the hurricane or the action of the volcano. He concluded by formally moving the adoption of the report and accounts.

Mr. WM. FORD seconded the motion.

Messrs. GRIFFITH, VEARS, THORNE, CUFF, and PARKER having addreesed the meeting,

The CHAIRMAN said: We have divided amongst you now upwards of £200,000, and kept your telegraph system in a perfect state. When the present Board were called in to take the management of the concern it was in a condition of absolute collapse. Mr. Griffith, I think, made some remarks as to the increase of the ships' expenditure in harbour over that when they are in port. That is an obvious mistake, because there are no coals consumed in port. Of course the ships are maintained in a state of readiness to go away at a moment's notice, and the fixed expenditure is the same, but there is no cost for coal. As to our getting contractors to maintain our cables, I think it would surprise you to know, if you approached them with such a suggestion, how much they would charge. The most moderate tender that you would get would take away the whole of your revenue. We know very well what contractors expect for such a business as that, and at such a distance from home. I do not think anybody would entertain it. As to the issue of debentures, we do not intend to issue them at a discount, nor to give any commission on them. I do not think it is necessary for me to reply to the remarks of Mr. Parker. I have said what the position of the Directors in this concern is over and over again. As you know, under the old Board, a committee of shareholders was formed to inquire into the circumstances of that Company, and as a result the present Directors were elected by the committee, and they had no interest in the inception of this unfortunate affair. Certain terms were proposed to them, and you got the most experienced men in telegraphy in this country to manage your business, and you agreed to pay them for their services. That is all I can say on the matter.

The resolution was then put to the vote, and it was carried with two dissentients.

On the motion of the CHAIRMAN, seconded by Mr. HOLMES, Mr. W. Andrews was re-elected a Director of the Company, as was also Sir James Anderson on the motion of the CHAIRMAN, seconded by Mr. W. FORD.

Mr. ANDREWS and Sir JAMES ANDERSON having duly returned thanks for this renewed mark of the confidence of the shareholders in them,

Mr. VEARS proposed the re-appointment of the auditor, Mr. John G. Griffiths, F.C.A., which was seconded by Mr. WM. GRIFFITH, and also agreed to.

Mr. VEARS then proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. HARLAND, and the proceedings terminated.

London Platino-Brazilian Telegraph Company (Limited).

Report of the Directors to be presented to the shareholders at the ninth ordinary general meeting to be held at the offices of the Company, Winchester House, 5C, Old Broad-street, E.C., on Monday, 23rd May, at twelve o'clock:—

The net revenue of the year, after providing for debenture interest and income-tax, is £13,026. 9s. 4d., and £1,171. 7s. 4d. is brought in from the preceding year's account, making a total of £14,197. 16s. 8d. to the credit of revenue account. The interim dividend of 2s. per share, paid on the 22nd November, 1886, absorbed £3,834. 16s., leaving therefore to be dealt with £10,363. 0s. 8d, from which the directors propose to appropriate £150 in further reduction of the item of expenses of issue of the Six per Cent. Debentures, to add £1,000 to the reserve fund, and to apply £7,669. 12s. in payment of a final dividend of 4s. per share, making, with the interim dividend already paid, a distribution at the rate of 3 per cent. per annum (as against 1 per cent. paid last year), leaving a balance of £1,543. 8s. 8d. to be carried forward. The directors are pleased to be able to state that the accounts show a marked increase in the receipts from the land lines in Uruguay. It is satisfactory also to find a considerable increase in the amount received from the Western and Brazilian Company in respect of the cable system. The difference between that company and this has not yet been adjusted, and this Company's claim remains unsettled. The submarine cables and land lines are in good working order. According to the Articles of Association, John Hollocombe, Esq., a director of the Company, retires by rotation, and offers himself for re-election. Messrs. Deloitte, Dever, Griffiths and Co., the auditors, also retire at this meeting, and offer themselves for re-election.

CITY NOTES.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 13th inst. were £3,707.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th May are £2,287, as compared with £2,767 in the corresponding period of 1886. The January receipts, estimated at £5,735, realised £5,807.

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED).—The Jablochkoff and General Electricity Company has been joined by Messrs. Manville and Madgen, and the name of the company has been changed to the United Electrical Engineering Company (Limited). We understand that the company will shortly bring out a new type of arc lamp, and will also make a speciality of secondary generators under Jablochkoff's patent.

APPOINTMENT.—The Telegraph Manufacturing Company of the Britannia Telegraph Works, Helsby, near Warrington, have appointed Mr. Alfred Whalley to be their London representative for telegraph, telephone and electrical signalling apparatus. The company contemplate opening a depôt in London; meantime Mr. Whalley's address is No. 2, Whitehead's-grove, Chelsea, S.W.

NOTES.

SECONDARY BATTERY QUESTIONS IN BRUSSELS.—In reply to the letter of "Interested" on the above subject, our Brussels correspondent will write further on the subject in our next issue.

NEW YORK.—An annual saving of $15,000 has been effected by the substitution of electric light for gas in the New York General Post Office. The present system of lighting costs $45,000 per annum.

TRANSFORMER PATENTS IN GERMANY.—The German Patent Office has finally refused to recognise the claims of Zipernowski, Déri, and Blateny for the use of a closed magnetic circuit and the coupling of transformers in parallel.

GUADALAJARA, SPAIN.—Guadalajara, a town of 8,000 inhabitants, is to be lit on the Zipernowski-Déri system, motive power being obtained from a turbine capable of developing 40 horse-power at a distance of two miles from the town.

PROJECTED CABLE BETWEEN TUNIS AND MARSEILLES.—The French journals announce "under all reserve" that their Government has under consideration a project for laying a submarine cable between Tunis, Bizerte, and Marseilles. An annual subvention of 100,000 francs is spoken of.

THE "ENGINEERING" DIRECTORY.—We have received a copy of a useful trade list, published and circulated gratuitously by the proprietors of *Engineering*, and which consists of a classified list of the names and addresses of advertisers in that journal, together with a separate list of their telegraphic addresses.

CHICAGO.—The American *Sanitary Engineer* states that the gas and electric light companies of Chicago have been amalgamated under the title of the Gas Trust Company, which will now control all the lighting of the city. It is intended chiefly to develop electric lighting, and several new plants will be erected for this purpose.

A RASH EXPERIMENT.—We regret to note that a fatal accident has occurred in New York to a man named Simpson, who was in charge of a dynamo machine at the Adams Express Building, Broadway. It appears that Simpson purposely laid hold of the terminals of the machine in order to show some visitors how much current he could stand.

TELEPHONING BETWEEN BRUSSELS AND HAVRE.—Since the completion of the line between Paris and Havre conversations have been held between the latter place and Brussels, the distance being about 350 miles. The articulation is said to have been very nearly as good as in the shorter line.

TELEPHONE CONTRACT OPEN.—The Haslingden Local Board require tenders for the construction of a line of telephonic communication between the fire station at the Public Hall, Haslingden, and the Waterworks Office at Rawtenstall. Specifications and forms of tender can be had of Mr. T. Woodcock, clerk, Public Hall, Haslingden. Tenders must be received by 12 noon on 2nd June.

PROGRESS OF THE ELECTRIC LIGHT IN JAPAN.—At Tokio, Japan, a company, with a capital of £40,000, has been formed to supply the electric light from central stations. It is proposed to establish five centres in Tokio, two at Osaka, two at Nogoya, and one at Kioto. The company has received an order to supply the Imperial Palace with current for 2,000 incandescent and 100 arc lamps for their first central station.

MEXICO.—We are sorry to learn that the citizens of Mexico have just been treated to the novel spectacle of a bull fight by electric light. An immense crowd thronged to the Colon Plaza to witness it, President Diez and several members of his Cabinet figuring among the spectators. The sport was particularly "good," the unfamiliar glare having had the effect of rousing the bulls to an unusually high pitch of fury.

"ANNUAIRE DE L'ELECTRICITÉ."—We have received a copy of the fifth annual issue of the "Annuaire de l'Electricité." For those who are not acquainted with this useful publication we may mention that its contents consist of a brief directory of the electrical trades and professions for each country of Europe, together with information concerning the various Government services and learned societies, &c., connected with electricity.

A FERRIC-CHLORIDE CELL.—Mr. H. N. Warren, writing in the *Chemical News*, states that for zinc carbon cells an exciting liquid superior to bichromate of potassium may be made by taking a strong solution of ferric chloride, slightly acidified, and mixed with bromine (in what proportion does not appear). The bromine serves to reoxidise the ferrous chloride formed, and when consumed may be again set free by the addition of bleaching powder.

NIAGARA FALLS.—It is stated that the Buffalo Electric Light Company has entered into a contract with the Niagara Falls Hydraulic Tunnel and Power Company to take 10,000 horse-power, at 15 dollars per horse-power per annum, for lighting the city and manufacturing purposes. The route for the proposed cable has been surveyed from Niagara Falls, a distance of twenty miles. Negotiations are also pending for lighting and supplying power to other towns in the vicinity.

THE TELEPHONE IN THE FRENCH ARMY.—Since the year 1882, when the telephone was first employed in the French army, during the field manœuvres, much attention has been paid to its development, especially for out-post service. Magneto instruments, dispensing with batteries, are exclusively employed, and a special telephone corps is now being organised, which will have an organisation distinct from that of the military telegraphs, its purpose being, in fact, wholly different.

AN ELECTRIC WATER HEATER.—The German Edison Company is selling an electric water heater for heating shaving water, boiling an egg, or making coffee, &c., &c. It consists simply of a metallic vessel containing an inner casing within which is placed a coil of German silver. A litre of water can be made to boil in twelve minutes with a current of four amperes and 100 volts, and at a cost of about 2d., according to the tariff at present in force at Berlin. The convenience of such an apparatus is so great that its introduction in all cases of central station lighting is probably a mere question of time.

OBITUARY.—We regret to announce the death, at Kirkcaldy, on May 15th, of Mr. James Townsend, local manager to the National Telephone Company in their Scottish South Central District. Mr. Townsend was an electrician, and more especially a telephonist, of great promise, and much esteemed by his employers and by all who knew him. Deceased was elected an Associate of the Society of Telegraph-Engineers and Electricians only about six weeks ago. He was assistant honorary secretary to the East of Scotland Naturalist Society, and the author of several papers on electrical subjects read before that body

CONVERSAZIONE OF THE INSTITUTE OF CIVIL ENGINEERS.—The annual *conversazione* of the Institute of Civil Engineers was held on Wednesday last at the South Kensington Museum. The guests were received by Mr. Woods (the president of the institute) and Miss Woods, and upwards of 3,000 invitations were accepted. In addition to the inexhaustible artistic attrac-

Digitized by Google

tions of the museum, a series of entertainments, musical and otherwise, were held in the lecture theatre, and two recitations were given by the ever-popular Mr. Corney Grain. In the North Court the string band of the Royal Artillery played a selection of music.

LIVERPOOL AND MANCHESTER TELEPHONIC COMMUNICATION.—Telephonic communication between Liverpool and Manchester was interrupted from Friday to Monday last, owing to the fall of a large tree, which broke down the lines near Wigan. The numerous inquiries which resulted from the accident afford an evidence of the extent to which inter-urban telephony now enters into the commercial life of the northern towns. We imagine that if London were entirely cut off from telephonic communication with neighbouring towns, even for a week together, no one would find their equanamity much disturbed thereby.

THE USE OF THE DYNAMO MACHINE IN TELEGRAPHY.—It is well known that several years ago this arrangement was successfully carried out in Calcutta by the late Mr. Louis Schwendler. Since then Dr. Liego has introduced the system at New York, where several of the telegraph companies now work their lines from a dynamo. Upon the suggestion of M. Picard a similar plan is now being tried in the central telegraph office at Paris, and is giving entire satisfaction. It is said that fast speed Wheatstone instruments are worked as easily as the Hughes type writer or local single-needle circuits. The dynamo in use gives 120 volts.

ELECTRICITY AND SHIPBUILDING.—The steel screw steamer, "Albania," which was launched from the yard of Messrs. A. M'Millan and Son, on Thursday last, had the whole of her plates drilled and riveted by means of electro-magnetic machine tools, designed by Messrs. F. J. Rowan, C.E., and J. M'Millan, jun. We shall shortly give a full illustrated description of these machines. We may state that it is anticipated that the adoption of this method of drilling will lead to a possible reduction in the weights of the hulls of vessels, owing to the greater accuracy with which the work can be carried out. If this anticipation be realised the extra cost will be more than compensated without taking into account the saving of time and labour.

ELECTRIC LIGHTHOUSES AND THE CORK HARBOUR BOARD.—At a meeting of the Cork Harbour Board, on the 11th inst., a resolution was proposed and carried to the effect that the question of lighthouse illuminants should be re-investigated by the Trinity House. From the remarks of the speakers it appeared that most of them were under the impression that it had been conclusively proved that in thick weather gas had a greater penetrative power than electricity. But it should be noted that, although this statement was originally made on good authority, yet it has never received confirmation by subsequent observers. On this point we would refer those interested to the report of the French Commission, of which some account is given in another column.

THE DEPREZ-ABDANK ELECTRIC BELL SYSTEM.—The method of working electric bells devised by MM. Deprez and Abdank bids fair in time almost to supersede the use of the battery. The current is generated by the vibration of a coil of wire between the poles of a pair of small magnets, the coil being fixed on the end of a stiff blade-spring, which is set in vibration by a slight pull. The cheapness and simplicity of the method is obvious, while as to its efficiency we are informed that on a Continental railway the arrangement has been at work for a long while signalling over a distance of 600 miles. Much, however, as we appreciate the merits of this system, we have been not a little amused by the comments of the daily press, one of the journals winding up its account with the exclamation, "Surely an unexampled instance of scientific research!"

THE ENOS ELECTRIC RAILWAY.—The Enos electric railway is practically a development of the telpherage system invented in this country. There are, however, certain differences in detail which would naturally be made in the endeavour to adapt the system to passenger traffic. Thus, the conductors become stouter, and rest on an iron trestle supported by iron standards. The second rail is set underneath the first, and the car runs with one pair of wheels on the upper and one on the lower rail, the motor being placed in circuit directly through the car wheels. A street railway of this description is already in use at Los Angeles, California, and efforts are now being made to obtain permission to build a similar line in Boston. About twelve months ago we chronicled the experimental trial in the neighbourhood of Boston of an almost identical system, under the name of the Chandler Overhead Electric Railway.

PRIVATE VERSUS CENTRAL STATION LIGHTING.—We are sorry to find ourselves unable to agree with Herr Hegener when (according to the *Gas World*) he expressed the opinion that although a gasworks may possibly be upon good terms with a private producer of the electric light, yet a central electric lighting company must needs regard him as a mortal enemy. We venture to think, on the other hand, that the existence of any private electric lighting emphasises the demand and guarantees the ultimate success of central station lighting. If electric lighting is so much wanted that in numerous cases it is considered worth while by private persons to go to the trouble and expense of producing it for themselves, what is likely to be the demand when the current is brought to everybody's door? Meanwhile, it is certain that all prospective electric lighting stations owe a debt of gratitude to those individuals who are familiarising the public with the beauties and advantages of electricity as a lighting agent.

THE PABST TELEGRAPH BATTERY.—The *Revue Internationale* contains a glowing account of the merits of a new cell adopted for the telegraphic service, and introduced by Dr. Conrad Pabst. The negative element consists of a carbon plate, which is "prepared" in some way left unexplained with oxide of zinc. The positive element is a cubical block of iron. The solution consists of chloride of zinc, and one of the chief claims on behalf of the battery is that owing to the deliquesent properties of this salt no addition of water is ever required, provided that the battery be kept in a place not too dry and warm. Further than this, the element is said to be self-regenerative, acting by the absorption of oxygen from the air, so that it requires no other attention than the renewal of the positive plate at long intervals. The action of the battery would appear to depend upon the conversion of ferrous chloride into ferric chloride by absorption of atmospheric oxygen, the ferric salt becoming ferrous by contact with the positive element. The utilization of this reaction for the purpose of depolarisation is, we may observe, by no means a novelty, and will be found to be fully described on page 159 of the second edition of "Sprague's Electricity."

TELEPHONE ON THE BRAIN.—An American physician has (says the *St. James's Gazette*) made a terrible discovery about the telephone. He declares—and he backs his statement by figures—that the mortality among subscribers to the telephone is three times greater than among people who do not avail themselves of its dangerous delights. The diseases most fre-

Digitized by Google

quently produced by the constant use of the instrument are cerebral, pulmonary, and nervous. Indeed, "telephonism" may be briefly described as over-excitement of the nervous system. Science may yet throw further light upon the matter; and in the meantime people who use the telephone had better console themselves with the reflection that the American doctor is probably a faddist. But, whatever may be the sanitary effect of talking to a box and listening at a table, there can be no doubt that the occupation is bad for the temper. The hideous rumblings from an invisible world, the indistinct murmurings which so often represent the voice of your interlocutor, and the vain attempts to get "switched on" to somebody, render conversation by telephone a robust exercise of the virtue of patience and of that sweetness of temper which (in the male portion of mankind at least) is usually so soon exhausted.

THE GERMAN EDISON COMPANY AND MESSRS. SIEMENS AND HALSKE, OF BERLIN.—The report of the Board of Directors of the German Edison Company contains an announcement of some interest. Reference is first made to the development of the company's business, and attention is called to the great difficulties against which it has had to contend, especially those created by the unjustifiable imitations of the incandescent lamp patent. Although five judgments have been delivered in favour of the Edison Company, a definite decision has not yet been arrived at. It is complained that in the meantime the patent has run more than half its time, and the competition, against which thoroughly energetic steps cannot be taken, is continually increasing. The Edison Company has for years been carrying on fruitless negotiations with a view to liberating itself from the crippling influence of the French Compagnie Continentale. This state of affairs drew the Edison Company towards the firm of Siemens and Halske, and has led to an extension of the contract already existing with that firm. The title of the Edison Company will now be changed to the "Allgemeine Elektricitäts Gesellschaft" (Universal Electric Company). It may therefore, we assume, be understood that the interests of the Berlin Edison Company will henceforth be closely identified with those of the eminent firm above mentioned. The directors recommend the payment of a 4 per cent. dividend, and propose to increase their capital from £250,000 to £600,000.

LIVERPOOL AND TELEGRAPHIC DELAYS.—A feeling of dissatisfaction, says a local journal, on the part of Liverpool merchants, on the score of extraordinary delays in the telegraphic service between that city and the Continent, found expression on the 24th instant in a large and influentially attended public meeting, over which Sir William Forwood presided. Illustrating the delays in question, Sir William said it was found quicker and more convenient to send telegrams for Bremen and Havre round by New York than to entrust them to the direct service of the postal authorities. Mr. Hemelryk moved and Mr. W. D. Heynes seconded the following resolution, which was unanimously passed: "That this public meeting of merchants, brokers, and manufacturers of the city of Liverpool desires to bring under the notice of Her Majesty's Government the serious inconvenience and loss sustained by the trade of the port in consequence of the great delays which continue to exist in telegraphic communication with the Continent, and to protest against the dilatoriness of the postal authorities in removing the disabilities under which the trade is suffering." A further resolution, moved by Mr. H. Coke, and seconded by Mr. Blessey, was passed, urging the Postmaster-General to appropriate special wires for the convenience of messages from Liverpool direct to the Submarine Cable Company's offices in London, and suggesting an alteration in the system of registration of foreign telegrams at the London Post Office, to which much of the delay complained of is ascribed.

DR. ARON'S INTEGRATING AMPERE-METER.—Dr. Aron, of Berlin, some time ago devised an ampere-meter, based upon the principle adopted by Profs. Ayrton and Perry in their original watt-meter, in which the retardation of a clock pendulum indicated the expenditure of power. In Dr. Aron's instrument for measuring current (or volts) the bulb of the pendulum is replaced by a permanent magnet, and below this is placed a coil traversed by the main current. The pendulum is therefore subject to acceleration when the current passes. By comparing the time of this clock with standard time, and multiplying by a constant, the amperes or volts are integrated. The instrument has the obvious defect of depending upon the constancy of a permanent magnet, and when that magnet, as in the present case, swings to and fro in a variable field, it seems doubtful whether the calibration will long hold good. However, Dr. Aron, without altering this feature, has recently effected certain improvements in the construction, which are thus described in *Industries*:—"There are two pendulums, one with a magnet, the other with a common bulb. Each actuates its own escapement, and by a train of planet wheels the differential motion is registered on a dial similar to that of a speed counter or gas meter. Dr. Aron has also added a magnetic catch, which arrests both pendulums when no current is flowing, and releases them when one-tenth of an ampere or more is passing. By this addition the interval for rewinding the clock has been increased to about four weeks for average work."

"CROOKES' AMPERE-METER."—The heat-indicating paint devised some time ago by Mr. Henry Crookes has, we believe, already found a useful application in the engine room for the indication of hot bearings, and most probably for other similar purposes. We cannot, however, think him well advised in attempting to utilise the properties of this paint for the construction of an "ampere-meter." The utmost service which such an instrument could possibly render would be to indicate the passage of a current through a thin wire included in the circuit, but to attempt to measure the current by this means is obviously out of the question. However, Mr. Crookes shall describe the apparatus in his own language. "The instrument consists," he says, "essentially of a flat coil of thin wire, painted with heat indicating paint, and a screen round it, coated with ordinary red paint of the same shade. Coils of thick wire are placed in parallel circuit with the thin wire, and their resistances are so adjusted that by setting a commutator the point at which the indication of an excess of current takes place can be varied to suit different requirements. When an electric current is passed through the instrument the thin wire becomes warm, and when the current exceeds a certain quantity the temperature is raised sufficiently to change the colour of the paint to black, thus warning the man in charge that an excess of current is passing. On the current being reduced the temperature of the coil falls, and the paint returns to its original red colour." It will be seen from this that Mr. Crookes considers the instrument likely to be of use where a constant current has to be maintained in the circuit.

THE COREA.—PUTTING UP AN INSTALLATION UNDER DIFFICULTIES.—We mentioned some time ago that the King of Corea had ordered an extensive electric lighting plant from an American firm. The installation consists of 300 Edison lamps, and was first brought into use on February 20th, the anniversary of the birthday of the King's mother-in-law. A

Digitized by Google

clause in the contract stipulated that the American workmen engaged in putting up the apparatus were to be amenable to the Corean code of justice. This was a somewhat severe proviso, inasmuch as it is enacted that if any foreigner looks upon the face of the Monarch of Corea or of his Queen, even by accident, he shall forthwith be put to death, and that without mercy. However, the royal pair were good enough to restrain their curiosity during the presence of the workmen, and palanquins were provided in which the men were carried through the corridors of the palace, heralded by trumpeters, whose blasts gave notice to the King and Queen to keep out of the way. So far the story is amusing, but it is with sincere regret we have to record the death of Mr. W. M'Kay, the chief electrician of the party. After escaping the factitious dangers of an intrusion on the royal presence, Mr. M'Kay was accidentally shot on March 9th while explaining to a native the mechanism of a revolver. The man was immediately seized and would have been beheaded by order of the King had not Mr. M'Kay been able before he died to explain that the occurrence was purely accidental. After his death the Corean was again seized, and was only released on the urgent entreaty of the wife of the victim, to whom, moreover, he had only recently been married.

Electric Lighting at the Civil Service Bread Company's Bakery.—The Gülcher Electric Light and Power Company, of Battersea Foundry, Battersea, S.W., have just completed the lighting of the new factory built by the above company at Horseferry-road. The electric light has been adopted throughout the whole of the premises, and the installation consists of a No. 2 Admiralty type Gülcher dynamo machine, fitted with a heavy turned fly-wheel, which is driven through counter shafting from the 14 horse-power Otto gas engine used for driving the main line shafting. The dynamo has been placed upon a very solid foundation built with cement, and with a stone 6ft. long and 3ft. 6in. wide by 15in. thick, placed on the top, to which the dynamo is bolted. The current from the dynamo is first led to a main switch-board, which consists of a slate slab 3ft. 6in. long by 2ft. wide, supported in a wooden frame. This board carries 12 sub-circuit switches, and the current passes through 12 adjustable resistance coils. The installation consists of eight 2,000 candle-power Gülcher arc lamps and twenty-one 16 candle-power incandescent lamps. Each arc lamp is fitted with the company's patent rope gripper, which prevents the lamps accidentally slipping, and also avoids the necessity of in any way coiling up or fastening the lowering cord. The incandescent lamps are suspended by silk flexible cords, fitted with ceiling roses, cut-outs, and 10in. opal reflectors. The whole of the cables throughout the installation are run in continuous troughing, and every precaution has been taken to make the installation as complete in all its details as possible. The work has been carried out under the superintendence of Mr. Mountain, the general manager of the Gülcher Company.

The Electric Light and the Continental Gas Companies.—Some few weeks ago a rather singular step was taken by a syndicate of gas companies on the Continent. With a laudable desire to arrive, if possible, at some definite conclusion as to whether the time had yet come when electric lighting could be profitably combined with the manufacture of gas, it was determined to establish an electrical laboratory in which the question could receive a practical study from the point of view of the gas interest. The syndicate included the gas companies of Paris, Marseilles, Lyons, Madrid, and other places. The exact purpose and range of the experiments to be undertaken has not been made known, nor is it very clear what are the outstanding questions which the gas companies could hope to decide by experiments upon a laboratory scale. However, the syndicate was fortunate in securing the services of M. Monnier, who was at one time connected with the Marseilles Gas Company, and who is now Professor of Electricity at the Ecole Centrale of Paris. We have learnt with a good deal of interest that M. Monnier has already arrived at some very tangible results, of which we shall hope to hear further before long. The *Moniteur de l'Industrie du Gaz*, in a recent issue, made the following announcement:—"M. Monnier has obtained some marvellous results in connection with the electric light, and it is certain that the gas companies and the financiers for whom he is acting will not be slow to avail themselves, wherever a favourable opportunity exists, of the movement which has now established itself in favour of this mode of lighting." It is at least clear that the gas companies abroad are inclined to take a more intelligent and enlightened view of the subject than appears to be the case at present with those of our own country.

Lighting of No. 7, Stratton-street, Piccadilly.—The Gülcher Electric Light and Power Company have just completed the lighting of Lord Wolverton's town residence, in Stratton-street, Piccadilly. The installation, on account of the small space at the disposal of the contractors, was a somewhat difficult one to undertake, but has been most successfully completed. The plant consists of a 2 horse-power Otto gas engine, placed in the cellar under the road, the exhaust being led into a large exhaust chamber, and taken to the top of the roof by a much larger pipe than is usual. The engine bed foundation, consisting of a stone slab, is supported on two thicknesses of thick felt, these precautions being taken to avoid any chance of noise or vibration. A No. 1 Gülcher shunt-wound dynamo, fitted with a 2ft. diameter turned and balanced fly-wheel, is driven from the fly-wheel of the engine, and charges 27 Elwell-Parker accumulators, supported in varnished wooden trays, carried upon four oil insulators. In the dynamo and engine room a special switch-board is fixed, with which the following operations can be performed without any possible chance of short-circuiting or otherwise damaging the installation by switching on the wrong switches: 1st movement charges accumulators; 2nd movement discharges accumulators through the lamps; 3rd movement runs dynamo and accumulators in parallel; 4th movement runs lamps direct from the dynamo; 5th movement cuts lamps, dynamo, and accumulators out of circuit. On the left-hand side of the board a 5 contact switch is placed, enabling 5 extra cells to be added as the E.M.F. falls; measuring plugs for measuring the E.M.F. or current in any circuit are arranged on the same slate slab, also a voltmeter. This board was designed by Mr. Mountain. The fittings for the house throughout are of an artistic character.

Electric Lighthouses in France.—The last issue of the *Abstracts of Papers in Foreign Transactions and Periodicals*, published by the Institution of Civil Engineers, contains a translation of the report of the special commission appointed by the French Government on electric lighthouses, with especial reference to the question of flashing or scintillating *versus* steady or slowly revolving lights. There are at present existing seven electric lighthouses on the French coast, of which all but two give rapid flashes on a system devised by M. Allard. The commission arrived at the general conclusion that "*electric lights have greater illuminating power than oil lights for all weathers and at all distances*; and the report concludes with the expression of the following opinions;—"The disposition of electric scintillating

Digitized by Google

lights inaugurated by M. Allard, and applied on the coast of France, has advantages over all other systems of illumination employed hitherto in France or elsewhere. It seems to be almost faultless, optically and mechanically, and as nearly perfect as possible in the present state of knowledge. It may therefore be adopted, without modification (until further orders) in future installations of electric lighthouses in France. It will be expedient, however:—(1) Not to use the reserve oil lamp until means have been found of making it maintain distinctly the characteristic of the electric lamp. (2) To reduce to a minimum the dust from the burning carbons, and to protect from it the mechanism of the electric lamps, and of the revolving machinery of the optical apparatus. (3) To renounce the use of double power, until improvements of the apparatus allow of resorting to the ensuing increase of luminous intensity, which indeed is of little practical use. (4) To avoid, especially for landfall lighthouses, the introduction of a red flash among white flashes. The development of electric lighthouses should be carried on, in the first place, by their establishment at proper landfalls, and in the order of importance of these for navigation, namely:—Ouessant, Belle Ile, Barfleur, Mouth of the Gironde, Ile d'Yeu, Penmarch. Before proceeding further, the results of experience to be furnished by these lights should be awaited."

PROPOSED ELECTRIC LIGHTING ON THE LEES, FOLKESTONE.—The following is a summarised report of a discussion which took place on Wednesday last at a meeting of the Folkestone Town Council:—The Town Clerk said he had received additional correspondence as to the electric lighting of other towns. At Eastbourne the length of the frontage was 1,530 yards, which was lighted by sixteen arc lamps on the Brush system by the Hammond Electric Company at £400 per annum all the year through, from an hour after sunset to half-past 11 at night. The contract was terminable at three months' notice on either side. The company found all the plant, and kept it in repair, except damage arising from storms. The power of the lights was 1,000 candle nominal. The Mayor said they would require gas after half-past 11 at night, and he wanted to find out the hours such a proposal as that at Eastbourne would give them. He understood that the lighting by gas at present gave an average of ten hours per night throughout the year. Mr. Thompson said the time at Eastbourne would be an average of four hours per night. The Lees was nearly the same length as the frontage at Eastbourne. He calculated that the distance was about five-eighths of a mile. The Town Clerk said at Hastings the length was three-quarters of a mile, the contract was for three years, and the light was much appreciated. It was on the Brush system. There were fifteen arc lights of 2,000 candle-power, and the cost was £450 per annum. At Norwich, where electric lighting had been introduced, they gave it up four years ago, as it was not to be depended upon, and was double the price of gas. Mr. Thompson said at Dundalk, a small town, they were lighted by twenty-four arc lights of 3,000 candle-power for three years at £400 per annum. They had no lighting in June, end of July, and three days at full moon in every month, so that it could be put down at £600 for the whole of the year. It was considered there to effect a saving of £60 per year as compared with gas. Mr. Payer said next week he should move that tenders for lighting the Lees be invited. Mr. Sanders considered it a waste of time, as the lighting rate should be quite high enough as it was. Mr. Thompson doubted whether they should ask for tenders before they had made up their minds to have the electric light in the town. He did not see what they wanted the Lees lighted for. The electric light would not bring a single visitor. They did not come there to see the electric light. He could understand it if the town was lighted altogether by electricity; but he could not see the advantage of having the Lees lighted by electricity. But though he should be glad to get more information on it, he should not support the resolution proposed by Mr. Payer until they had determined whether they were going to have the light or not. Mr. Sanders said some of them had electric light on the brain. Ultimately it was arranged to have the question on the agenda paper for Wednesday week.

THE HISTORY OF THE STORAGE BATTERY.—Dr. P. H. Vander Wyde contributes to the *Electrical World* of New York the following brief history of the storage cell, up to the year 1881:—

1800. Volta invents the voltaic pile, a battery consisting of two different metals and a liquid.

1801. Gautherot discovers that the electrodes through which a voltaic battery has been discharged become capable of producing a current.

1801. Erman discovers that the electrode connected with the positive pole, when disconnected from the battery, will return a positive current; in fact, he discovers what we now call the principle of polarisation.

1801. Ritter, observing the same facts, succeeds in decomposing water by means of the polarised electrodes, and then demonstrates the inversion of the currents.

1802. Ritter makes the first secondary battery, consisting of a pile composed of discs of a single metal, copper, separated by a liquid, which becomes charged by passing the current of a voltaic battery through it, and produces all the phenomena of the primary, decomposing water, heating and burning wire, giving sparks, shocks, &c.

1803. Ritter constructs secondary batteries with plates of large size, and compares the results with those of smaller size.

1803. Ritter finds that copper is not the best metal for secondary batteries, and experiments with tin, zinc, lead, iron, bismuth, brass, silver, gold and platinum. He finds the best results with carburet of iron and oxide of manganese.

1805. Izarn describes in his *Manuel du Galvanism* five or six modifications of secondary batteries.

1826. Nobili deposited peroxide of lead on lead plate by means of a primary battery.

1837. Schönbein demonstrated that plates thus prepared possessed the property of giving a current like a primary battery.

1842. Grove made his famous gas battery based on the observation that when platinum plates had been used for the decomposition of water by the current, they would, when the battery was disconnected, cause the gases to recombine and in doing this produce an inverse current.

1843. Grove used plates covered with peroxides of metals.

1843. Siemens uses carbon plates.

1843. Wheatstone makes a secondary battery of platinum plates covered with peroxide of lead and potassium amalgam.

1853. Siemens uses carbon plates covered with oxide of lead converted into peroxide by the current.

1859. Planté finds that lead is the best metal for secondary batteries, and covers the surface with the peroxide by means of the primary current.

1861. Kirchhof makes the batteries of alternate plates of spongy lead and peroxide; also proposes to store up atmospheric electricty from insulated lightning rods, or to use magneto-electric machines for this purpose.

1866. Percival uses metal plates covered with crushed coke and powdered lead in diluted sulphuric acid.

1869. He uses a positive electrode of amalgamated zinc and a negative of lead.

1879. D'Arsonval uses carbon plates covered by oxid of lead and manganese and zinc plates in a solution of zinc sulphate.

1881. Faure creates surprise by a battery claimed to give superior results, and occuping less than a cubic foot of space, charged by a very slow process of forming.

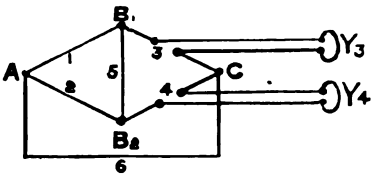
ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XXXIX.

BY OLIVER HEAVISIDE.

(Continued from page 6.)

This brings me to the subject of balancing rods against one another, either in the Christie or in the Felici differential arrangements, when placed in long solenoids; and to the similar question of balancing thick wires in the Christie, when the current in them is longitudinal. As I pointed out before (*Electrician*, May 30, 1886), if a wire be so thick that the effect of diffusion is sensible, it cannot be balanced in the Christie against a fine wire, but requires another thick wire in which the diffusion effect also occurs. I refer to true balances, independent of the manner of variation of the current, in which, therefore, the resistance of the one wire, though different at every moment, is yet precisely that of the other wire (or any constant multiple of it). Perhaps the best way to define the resistance is by Joule's RC^2. In the sinusoidal case a mean value is taken. According to this heat-generation formula, there always is a definite resistance *at a particular moment*, but what it may be will require elaborate calculation to find. This definition of the resistance to suit the instantaneous value of the dissipativity does not agree precisely with the sinusoidal R′, which represents a mean value; but the sinusoidal R′ has important recommendations which outweigh this disadvantage.



Suppose now we want to balance an iron wire against a copper wire, the wires being straight and long, though not so long as to require the consideration of electrostatic capacity. For simplicity, first let the ratio be one of equality, so that sides 1 and 2 in the Christie are any precisely equal admissible arrangements, which may be mere resistances. Let the iron wire be in side 3, the copper wire in side 4. We have to make side 3 an electrical full-sized copy of side 4. For definiteness, imagine Y_3 and Y_4 to be short-circuits, that one of the two parallel lines leading to either is the wire under test, whilst the other is a return tube, thin and concentric.

First, in accordance with the description of how to make copies (*Electrician*, March 11, 1887, p. 391), make the resistances of the two returns equal. Next, make the inductances due to the magnetic field in the space between wires and returns equal, by proper distance of returns, or by inductometers in sequence with sides 3 and 4. There is now left only the wires themselves to be equalised. First, their steady resistances require to be equal. Next, their steady inductances ($\frac{1}{2}\mu \times$ length). These two conditions will give balance to infinitely slow variations of current, and can be satisfied with wires of all sorts of sizes and lengths. But we require to make them balance during rapid variations of any kind. For, instance, a very short impulse will cause a mere surface current in the wires, that is, in appreciable strength, if they be thick; and still the wires must balance. The full balance is secured by a third condition, viz, that the time-constants of diffusion shall be equal. This time-constant is $\mu k \pi c^2$, where μ is the inductivity, k the conductivity, and c the radius of a wire. Or, $\mu l/R$, the quotient of the inductivity by the resistance per unit length (or any multiple that we may find convenient of this quotient).

Thus, if the iron has inductivity 100, that of copper being 1, whilst k for copper is about six times the value for iron, the copper wire must have a radius of about four times that of the iron. This is indispensable. Fixing thus the relative diameters, the rest is easy, by properly choosing the lengths. In a similar manner we may have the resistances in any proportion, as for instance, to obviate the necessity of having wires of very different lengths, keeping, however, the proper ratio of diameters.

The following will be more satisfactory as a demonstration. If Z is the V/C operator, then $Z_1/Z_2 = Z_3/Z_4$ is the condition of balance (*Electrician*, March 11, 1887). So we have merely to examine the form of the Z of a straight wire. This is (*Electrician*, July 23, 1886),

$$Z = L_0 p + Rf, \quad . \quad . \quad . \quad . \quad . \quad (31c)$$

where f is the operator given by

$$f = \tfrac{1}{2} sc \frac{J_0(sc)}{J_1(sc)}; \qquad s^2 = -4\pi\mu k p. \quad . \quad . \quad (32c)$$

L_0 is the inductance other than that due to the wire itself, and R is its steady resistance. Using this form of Z in our general equation of balance, we see that if we take $s_3 c_3 = s_4 c_4$, that is, make the diffusion time-constants equal, we make $f_3 = f_4$, so that the balance is given by

$$\frac{Z_1}{Z_2} = \frac{R_3}{R_4} = \frac{L_{03}}{L_{04}} = \frac{r_3}{r_4}, \quad . \quad . \quad . \quad . \quad . \quad (33c)$$

where the additional r_3 and r_4 are for the two return sheaths or other resistances that may be in sides 3 and 4. Of course Z_1 and Z_2 may be R_1 and R_2, the resistances of sides 1 and 2, when they are mere resistances. In virtue of the equality of the diffusion time-constants, we may express the full conditions by adding to (33c) this:—

$$= \frac{\mu_3 l_3}{\mu_4 l_4}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (34c)$$

where l_3 and l_4 are the lengths of the two wires.

Although this balance is true, yet there will be one practical difficulty in the way. As is very easily shown by sliding a coil along an iron wire or rod, the inductivity often varies from place to place. But if the wire be made homogeneous the evil is cured.

Next, let it be required to balance a long iron against a long copper rod in long magnetising solenoids forming sides 3 and 4. Here the form of Z for the circuit of the solenoid is

$$Z = R + L_0 p + L p f^{-1} \quad . \quad . \quad . \quad . \quad (35c)$$

where R is the total resistance (as ordinarily understood) of the circuit of the solenoid, L_0 the total inductance ditto, due to the magnetic field everywhere except in the core, L that due to the core itself when the field is steady, and f as before, in (32c).

To balance the iron against the copper we therefore require, first, the equality of time constants of diffusion, or the iron rod should be one-fourth the radius of the copper; this being done,

$$\frac{Z_1}{Z_2} = \frac{R_3}{R_4} = \frac{L_{03}}{L_{04}} = \frac{L_3}{L_4} \quad . \quad . \quad . \quad . \quad . \quad . \quad (36c)$$

will complete the balance. The value of L (*i.e.*, L_3 or L_4) is

$$L = (2\pi c N)^2 \mu l, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (37c)$$

if N is the number of turns per unit length, and l the length of the solenoid. As for L_0, that is adjustable *ad lib.* nearly. The only failure will be due to want of homogeneity.

Lastly, balance two rods, one of iron the other of copper, against one another in Felici's arrangement, when each pair of coils consists of long coaxial solenoids, making two primaries and two secondaries, properly connected together. Let R_1, R_2 be the total resistances of the primary and the secondary circuit, L_{01}, L_{02} the total inductances, not counting the parts due to cores, M_0 the total mutual inductance, not counting the parts due to cores, L_1, L_2, and M those parts of the inductances, self and mutual, of the first pair of coils, due to the cores, and l_1, l_2, m the same for the second pair. The equations of E.M.F. in the primary and secondary are then, if F and f are the two core operators, as per (32c), and C_1, C_2 the primary and secondary currents,

$$\left.\begin{aligned} e &= R_1 C_1 + L_{01} p C_1 + M_0 p C_2 + F^{-1} p (L_1 C_1 + M C_2) \\ &\quad + f^{-1} p (l_1 C_1 + m C_2), \\ 0 &= R_2 C_2 + L_{02} p C_2 + M_0 p C_1 + F^{-1} p (L_2 C_2 + M C_1) \\ &\quad + f^{-1} p (l_2 C_2 + m C_1). \end{aligned}\right\} \quad (38c)$$

The first terms on the right are the E.M.F.'s used in the solenoid circuits against their resistance, the two following terms taken negatively the E.M.F.'s of induction not counting cores, and the last two taken negatively those due to the cores. To have a balance, C_2 must vanish. The second equation then gives

$$M_0 + M F^{-1} + m f^{-1} = 0 \quad . \quad . \quad . \quad . \quad (39c)$$

Digitized by Google

So $M_0 = 0$, or the mutual inductance of the circuits due to other causes than the cores, must vanish. Then, further,

$$F = f, \text{ and } M = -m \quad . \quad . \quad . \quad . \quad (40c)$$

So the diffusion time-constants of the cores must be equal, and the steady mutual inductance of one pair be cancelled by that of the other pair of coils, so far as dependent on the cores, as well, as before said, as dependent on the rest of the system. [When not counting cores is spoken of, it is not meant that *air* must be substituted. *Nothing* must be substituted.] The latter part is capable of external balancing. The former part to be balanced requires the value of

$$M = (2\pi c)^2 N_1 N_2 \mu l, \quad . \quad . \quad . \quad . \quad . \quad (41c)$$

when N_1, N_2 are the turns per unit length in the two coils of a transformer of length l, to have the same value for the two transformers.

The condition (39c) of course makes the primary equation independent of the secondary. It is then the same as if the secondary coils were removed.

This leads us to show the modification made in the equation of a transformer by the conductivity of its core. In (38c) we have merely to ignore the f terms, thus confining ourselves to one transformer, when the equations are given by the first lines. Now if the solenoids be of small depth, and there be no L externally, L_{01} and L_{02} become insignificant, and also M_0, provided the cores fill the coils. We have then

$$\left.\begin{aligned} e &= R_1 C_1 + F^{-1} p (L_1 C_1 + M C_2) \\ 0 &= R_2 C_2 + F^{-1} p (L_2 C_2 + M C_1) \end{aligned}\right\} \quad . \quad . \quad (42c)$$

which only differ from the equations when cores are non-conducting by the introduction of F. The first approximation to F is unity (when very slow variations take place). It may be written thus— $F^{-1} = A - Bp, \quad . \quad . \quad . \quad . \quad . \quad (43c)$

when A and B are positive functions of p^2, whose initial values are $A = 1$, $B = 0$. When the impressed force is sinusoidal, $p^2 = -n^2$, and A and B are constants. Then (42c) becomes

$$\left.\begin{aligned} e &= R_1 C_1 + (L_1 C_1 + M C_2) B n^2 + A p (L_1 C_1 + M C_2), \\ 0 &= R_2 C_2 + (L_2 C_2 + M C_1) B n^2 + A p (L_2 C_2 + M C_1), \end{aligned}\right\} \quad (44c)$$

From these, by elimination, we have

$$\frac{e}{C_1} = R_1 + L_1 R_2 \frac{B n^2 (R_2 + L_2 B n^2) + A^2 L_2 n^2 + A R_2 p}{(R_2 + L_2 B n^2)^2 + (L_2 A n)^2} \quad . \quad (45c)$$

showing the effective resistance and inductance of the primary as modified by the secondary *and* conducting core.

But it is very easy with iron cores, without excessive frequency, to make simpler formulæ suit. Let $z = \pi c^2 k \mu n$; then, if this is 10 or over (see *Electrician*, Feb. 4, 1887), we have

$$A = Bn = (2z)^{-\frac{1}{2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (46c)$$

approximately, which may be used in (44c), (45c) at once.

In an iron rod of only 1cm. radius, and $\mu = 100$, $k = 1/10{,}000$, the value of z is one-fifth of the frequency. If of 10cm. radius, it equals twenty times the frequency. With large values of z we have

$$\frac{e}{C_1} = R_1 + \frac{l_1 n}{1 + 2 l_2^2 n^2 / R_2 (R_2 + 2 l_2 n)} + \frac{R_2^2 l_1 p}{(R_2 + l_2 n)^2 + l_2^2 n^2} \quad . \quad (47c)$$

if L_1, L_2, and M, when divided by $(2z)^{\frac{1}{2}}$ become l_1, l_2, and m. This gives the primary current. And

$$\frac{e}{C_2} = -\left(\frac{R_1 R_2}{2mn} + \frac{R_1 L_2 + R_2 L_1}{M}\right) + \frac{R_1 R_2}{2mn^2} p \quad . \quad (48c)$$

gives the secondary current.

We can predict beforehand what these should lead to ultimately, from the general property that a secondary circuit, at sufficiently high frequencies, shuts out induction, or tends to bring $L_2 C_2 + M C_1$ to zero, giving the ratio of the currents at every moment. The coefficients of p in (47c) and (48c) tend to zero, and the current in the primary to be the same as if its resistance were increased by the amount $R_2 L_1 / L_2$. The core need not be solid. A cylinder will do as well, since the magnetisation does not penetrate deep. It should, however, be remembered that although at low frequencies it is the core that contributes the greater part of the inductance, so that the rest is then negligible, yet when that due to the core actually becomes negligible, the rest becomes relatively important, and should therefore be allowed for.

(To be continued.)

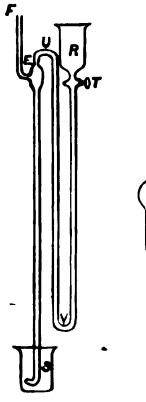
INCANDESCENT LAMP MANUFACTURE.—XV.

BY J. SWINBURNE.

Exhausting.

The next process is the most interesting, as well as the most difficult. Exhausting is generally done by the Sprengel pump, so it will be described first. The writer finds the Geissler pump preferable, as, if properly managed, it gives better vacuum, and is more easily worked. The reasons for this opinion will be given, and the experiments which led to it.

The Sprengel pump in its simplest form is described in most books on physics; but it is needless to remark that the Sprengel and Geissler pumps generally illustrated or commonly seen in physical laboratories would be of no use to the lamp maker. The essential part is a tube of small bore, down which mercury is allowed to fall in separate drops. The tube is so small that each drop forms a little plug or piston, which takes down any air in front of it. In practice the pumps have three or five of the fall tubes. Edison used to use, or still uses, a very simple form of single shaft pump; it is shown diagramatically in Fig. 11. It consists of a single fall tube with an elbow at E; the tube F goes to the lamp. Just above E the tube is contracted so as to make the mercury spurt through. R is a reservoir for mercury, T a tap to regulate the flow, and S gradually fills with mercury as the pump works. E is about forty inches above S. It will be as well to trace the action of this simple pump to show its defects, and to explain the problem that lamp makers have to deal with. It must not be supposed that Edison uses pumps with all these imperfections. The pump shown is a mere diagram; in practice it is made part of an automatic system. Suppose the lamp sealed on F, with a drying tube. R is filled with mercury and T is opened a little; the lower bend is filled with mercury, but the mercury cannot rise evenly in the two tubes, because air is imprisoned between the top of the mercury and the tap T. Every now and then the mercury will stop flowing, and will be pressed back, some bubbles of air thus escaping through R; this will go on till the mercury is nearly up to T. A little air will remain permanently below T, and the mercury will pour through in a thin stream which does not occupy the whole tube. The mercury will now rise in the tube U, and if the tube is of small bore it will run down to the contraction above E, pushing all the air before it. If the tube were of large bore the mercury would form a stream, and pour from U to E without expelling the air. This would render the pump useless, for as the vacuum was formed the air between U and E would expand, and every now and then a little would go through and spoil the vacuum. If the pump is properly made the mercury will fall past the tube F in separate drops, and each drop will form a little piston which pushes the air down in front of it. A single shaft Sprengel takes a long time to exhaust a lamp from the beginning; so in practice as much air as possible is removed by mechanical pumps before the mercury pump is started.



FIGS. 11 & 12.

Suppose the exhausting nearly complete, each drop of mercury falls about ten inches before it touches the column in the shaft. The points to be regarded in the arrangement of the contraction are, that the pump will exhaust as quickly as possible, and that it will do so with as little mercury as possible. The maximum speed is attained when one plug of mercury touches the top of the column in the shaft just as the next one reaches the contracted part of the fall tube. If the flow of mercury is increased, more plugs per minute go down the tube; but each plug takes down less air, so there is no advantage, and the mercury in R is used more quickly. If the reservoir R gets empty from any cause the mercury in the tube below the tap will fall about thirty inches. If the reservoir is now filled again the mercury will most likely take the air which is below the tap right round and spoil the vacuum. If the long bend V was not there at all the vacuum would be broken at once if R was

Digitized by Google

allowed to get empty. The position of T is therefore wrong; it should be so low that the mercury cannot fall below it. It might appear at first sight that anywhere between V and U would do, but if the flow of mercury through the contraction is regulated by the tap there would be a partial vacuum above it, and the glass stopcock must be regarded as useful in preventing the mercury from coming out, but not to be relied on to keep air out. The tap should therefore be at the bottom of the bend V, so as to be under pressure, and the tube above it should be so large in bore that the mercury does not form plugs or imprison air. If the mechanical pump is used to start the vacuum there is no need for R to be above E, it need only be less than thirty inches below it. When the pump has been running some little time, air which has been sticking to the sides of the tube V U will come off and go round through E, spoiling the vacuum. To prevent this an air trap must be inserted in the upper part of the tube V U; this is shown in Fig. 12. Some put a little loose glass cup, shown dotted, inside the trap, so that it floats up and covers the end of the tube without closing it. The object is to prevent bubbles coming straight up the centre. Bubbles never do go up the centre of a long tube of mercury, as, if they once touch the side, they do not again go to the centre. Mercury does not wet glass. Such a trap as this would give trouble if the pump was not started by a mechanical exhaust, because it would contain a lot of air to begin with, and as the vacuum was produced this air would expand and go round U. If the trap is exhausted well before the mercury is admitted to it, there is no danger of a bubble of air getting round just as the process is complete. The air in the trap also acts as a sort of cushion, and makes it more difficult to regulate the flow of the mercury. Instead of the mercury coming through uniformly it stays above the contraction, while mercury flows continuously through the tap till the air is compressed enough to overcome the capillary attraction of the mercury for itself at the contraction at E. The mercury then flows through with a rush till the air is expanded, and stops again, and so on. The best way to avoid this is to have the reservoir R only a few inches above the level of E, and to make the contracted part of the tube of such size that it will work well with the tap fully open. Of course, this takes more mercury.

The best diameter for the fall tube is about one-tenth of an inch; a thick wall barometer tube is generally used. When the vacuum is good the little drops of mercury rattle down, and subject the tube to a series of little taps, due to the lateral pressure caused by the inertia of the mercury. After continued use most glass tube breaks just where the rattling takes place. Probably thin walled tube would be more durable, but it is difficult to get it uniform enough in bore to be of use. Springel tubes often present all sorts of curious fractures.

Care must be taken to put the connection for the mechanical exhaust in the right place. If it were made, say, at F, it would be necessary to seal the tube off every time, as no glass tap can be depended on. The joint must therefore be made between the top and U. When there is no vacuum in the pumps the mercury in V U will fall to the same level as that in the reservoir R, so the tube to the mechanical exhaust can be just above. Before turning on mercury a tap in the mechanical exhaust is opened, and the pump, lamp, and various tubes exhausted as well as possible. The mercury tap is then opened, and the mercury runs round into the fall tube and also runs thirty inches or so up the mechanical exhaust tube. The mechanical exhaust may be left on or not. If it is shut off, and the tap leaks a little, the air wil not get round into the lamp till the air inside the tube is nearly at the pressure of the atmosphere. If it is not shut off there is another danger, for if some other pump in the system is broken the air rushes in and spoils the vacuum of the mechanical pumps, and all the pumps connected with that pipe have their vacuums broken. If the lamps are not being "run on the pumps" this means loss of time and money, but all lamps that are running will be spoiled. The writer always shuts each pump off as soon as it is started, and inserts a globe between the tap and the pump, so that if the tube does leak a little it takes so long to fill the globe that the lamps are finished in safety.

CORRESPONDENCE.

ELECTRO-CHEMICAL EQUIVALENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Swinburne (p. 33) puts the real point at issue out of sight when he states my view as meaning that "electro chemists should not write thermo-chemical equations in the same way as other chemists." I am not aware that there is any absolute mode of writing thermo-electric equations as yet adopted; in fact, the whole subject of thermo-chemistry is in its infancy, and few chemists know anything much about it. The few authorities who deal with it use all sorts of units, calories per gramme, or units per lb. of substance, calories per equivalent, calories per molecule, &c. Even for chemical considerations, it would seem that the energy corresponding to the chemical equivalent would be more useful, because less confusing, than that of the modern molecule of varying equivalence, which requires a succession of arithmetical operations at every change of chemical constitution.

But is there really any law of science or common sense which requires us always to use the same expressions or symbols for substances when we are dealing with them for different purposes? Do we not find sulphuric acid written $SO_3 H_2 O$, $H_2 SO_4$, $\left.\begin{matrix} SO_2 \\ H_2 \end{matrix}\right\} O_2$, and perhaps half-a-dozen other ways—and every one of these rightly and usefully—as illustrating differing conceptions of the construction of the substance? We generally use the new notation and atomic values in our chemical writing, because they are now generally adopted, and cover a number of considerations which have chemical importance; but the old notation and equivalents have many advantages in practical chemistry, and no one can say that in course of time the chemists may not revert to them. In electricity, however, the equivalent notation is most certainly superior in intelligibility and practical convenience; the only reason against its use in electrical writings is the confusion which would arise from the use of two systems of chemical expression. As, however, the one thing absolutely certain in electrolytic reactions is the relation of unit electric quantity to unitary equivalents of substances, that relation is the fundamental one which our expressions ought to convey where possible. It hardly needs argument, therefore, to show that where we want to deal with the relation of energy to electrolytic reactions, we shall do best to connect our ideas with the absolute facts, with the real material equivalents which take part in the electric actions, not with the merely artificial symbols adopted to convey an entirely different set of chemical actions.

But the whole gist of the question is, what constant is the best to employ in the conversion of energy from one form to another, so as to show how the energy of chemical affinity is related to the energy involved in electromotive force? Should the constant be a single one, that related to the one equivalent of matter and one unit of electricity, or should it be variable with the constitution of the chemical molecules, containing one, two, three or more such equivalents? That is, shall the *constant* be a variable or not?

Mr. Swinburne says that the value I give "1 volt = 23,287·7 calories is, of course, inaccurate." I must really ask him not to bear false witness against me, and make me responsible for things I do not say. I did say "to speak of expressing volts in calories is absurd." I did give a value for something else, which value I expressly said was calculated for an "undetermined" electric unit of which no human being knows the real value, though our professors work it out to half a dozen decimal places, when they want to show something to suit their purposes. As he says, "of course" my figure may be inaccurate. In my letter, p. 7, I said, "in the present uncertainty I have reckoned." In my "Electricity," where all this subject is fully discussed, and where there are hundreds of calculations and many tables involved in it, I explained that I did not think it worth while to alter all this until the values of the various elementary data were finally settled. Meantime, the actual figures I give can be corrected to any value of any of the data preferred by a simple constant when desired. The figure 23,000, or thereabouts, in calories, is simply the equiva-

Digitized by Google

lent, in the Gramme system, of the unit I proposed under the name of the *Equi-volt*, and described in the *English Mechanic*, 27th October, 1871. I there said, after working out the idea of the mechanical equivalent of the current doing one equivalent of chemical work under unit electrical conditions, "This result is of supreme importance, for it gives a definite meaning to the volt, which has hitherto been too ideal to grasp. It tells us that 'energy' equivalent to 4,673 foot-pounds exerted upon a chain, each link of which is an equivalent of matter, weighed in grains, converts that chain into an electric circuit under a tension of one volt at the source of the force."

As Mr. Swinburne does not know what a "volt-ohm-ampere-second" is, and that is the first step to realising the actual relation of volts and calories, I may explain that it is what is called a joule or joulad, the energy expended during one second, by an ampere current, in an ohm, under one volt of E.M.F. (this last is, of course, involved in the others, even if not expressed). When we know how many seconds an ampere-current requires to effect one equivalent of chemical decomposition, the two figures give us the equi-volt, the constant which expresses the relation between chemical energy and the electromotive force that energy can set up in a chemical reaction. The sum of the matter is simple; the potential energy of a chemical reaction, or that of the sum of a series of reactions, occurring in a circuit, can become kinetic, either as heat (expressible as calories or foot-pounds), or as electric work (calories or foot-pounds), and that electric work involves the setting up of an E.M.F. expressed in volts, which we know, as a matter of fact, is capable of generating that work in a unit circuit. The uncertainty of the actual value is due to the fact that we do not know exactly as yet what an ampere current is, how to get a real ohm, what we mean by a volt, the work value of the volt-ampere, or the exact mechanical equivalent of heat. We can as yet only recognise our knowledge as approximate, try to improve it, but still perceive that our errors of measurement do not affect the natural principles concerned.

Mr. Swinburne misses this when he says, "in the meantime H_2O stands for 18 grams of water, and however much we might like to call it 9 grams, we are not at liberty to call it so." That is not the pivot of the argument. We are not concerned about H_2O except when we want to deal with water itself. We are fixing the unit *ion* of electrolytic actions, and the question is whether we shall use the true natural one, the single atom of hydrogen, or double it merely because two atoms are taken up in the oxygen compound H_2O, while one suffices in HCl, and one suffices in a large number of electrolytes.—Yours, &c.,

JOHN T. SPRAGUE.

ELECTRIC LIGHTING TENDERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The thanks of all honest electrical engineers are due to you for your recent article on what you mildly term the discreditable episode at Southport. This case is by no means a solitary one, and I have myself come across several equally discreditable and equally disastrous in result. The Union Steamship Company invited tenders for their ship the "Trojan." The tenders duly arrived, and varied from the highest to the lowest in the proportion of about five to one. Now, the directors of that line are not electricians, but they are practical men, and, being such, they agreed amongst themselves that "something was wrong;" they did not understand what, but there was one clear way out of the difficulty, and that one they took. The project for lighting the ship was consequently abandoned.

Quite recently, in tendering for a supply of cable of a certain size and certain insulation resistance I was fortunate enough to hear what the tenders amounted to. I heard from the consulting engineer that the lowest tender—and, moreover, the one accepted—was 40 per cent. lower than the special net price quoted by a maker to us. Now, as that maker was not tendering, but knew that we were, it is impossible to arrive at any other conclusion than that the firm whose tender was accepted were considerable losers. They were determined *to get the work at any price.*

I could give other examples, and no doubt many others could do the same. The question is—How far is such a thing to go? Surrounded by numerous elephantine monsters, the Act of 1882, the price of copper, vested interests, &c., are we going to add to the list the trade itself, and drift down to that most exemplary and commendable of all methods of trading which may be familiarly expressed in the words, "Given away with a pound of tea?" Let me illustrate it. The vendor of transformers will advertise thus:—"To every purchaser of our celebrated transformer will be given away *absolutely free of all cost whatever* one coefficient of self-induction." I say this in all seriousness, and let those who are inclined to laugh pause a moment and ask themselves why the electric lighting business drags on so slowly. Is the Act of 1882 the sole cause? No, they will come to the conclusion that bad work, undertaken at a price which could not possibly pay, in numbers of instances has done as much as anything else to bring discredit on electric lighting enterprise.

There is no excuse why tenders should vary in amount very widely, provided the engineer will honestly estimate for that plant which the laws of economy would suggest; but, depend upon it, directly he diverges—in order to keep down his prices and make his bid attractive—from those considerations of economy which must be paramount in all engineering questions, his undertakings will most surely drift into the chasm of dismal failure which has engulfed so many good schemes in the past.—Yours, &c.,

J. M. V. MONEY-KENT.

Connaught Mansions, Victoria-street, S.W.,
19th May, 1887.

THE ELECTRIC LIGHT IN INDIA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, writing upon the subject of "Electric Light in India" in your issue of April 15th, makes some statements which are quite incorrect, and which I hope you will, in justice to me, rectify.

After enumerating several installations in this country, most of which have been working for years past, he winds up his letter by saying that "the entire work, mechanical and electrical, was done by native hands, under the superintendence of Mr. Fischer, of the Indian Electric Light Company." As a matter of fact Mr. Fischer had absolutely nothing to do with at least two of the installations, viz., the Royal Bombay Yacht Club and the Clock Tower, both of these having been erected and worked under my supervision only.

The club installation consisted of 300 Swan-Edison 100-volt lamps, distributed over the front of the club, in addition to the 300 in use every night, and were worked by means of two F 2 Victoria compound dynamos. Brush arcs only were used for lighting the Clock Tower, and the windows and clock were certainly *not* painted a light green.—Yours, &c.,

J. O. S. ELMORE, late Eastern Electric Light
May 5th. and Power Company (Limited).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been drawn to a letter headed "The Electric Light in India," on p. 495 of your issue dated 15th April last. Your correspondent, after touching upon the illuminations up country, proceeds to describe what was done in Bombay on the occasion of the Jubilee. I would beg to point out certain discrepancies in the article:—

1. The Bombay Yacht Club has been lighted for years by incandescent lamps with plant purchased from a company with which Mr. Fischer had no connection.

2. The Clock Tower was lighted independently of either Mr. Fischer's plant or superintendence.

3. As regards the lighting of the Victoria Terminus, I am in a position to state that the most Mr. Fischer did was to supply the plant required at a very fair remuneration. The electric part of the work was carried out by my department, while the mechanical details were supervised by one of the company's locomotive-engineers.—Yours, &c.,

A. R. M. SIMKINS, Telegraph Superintendent.

Great Indian Peninsula Railway Company,

THE TELEGRAPH AND MILITARY TACTICS.

We are glad to notice that the officers of that branch of the army which is most closely associated with the application of telegraphy to military purposes are still actively encouraging its extension. Colonel HALE'S and Major BERESFORD'S papers, at the UNITED SERVICE INSTITUTION, last Friday, and the discussion which followed, are calculated to have good results sooner or later, notwithstanding the discouraging observations of Lord WOLSELEY, who presided. It is undoubtedly discouraging to hear propositions of this kind discussed, not on their merits, but on their chance, or rather their certainty, of being rejected at head-quarters. According to this high authority, if you bring a useful suggestion to the notice of the WAR OFFICE an official in one room writes a formal minute to an official in the next room, and in due time receives a formal minute in return, the upshot of which is that the matter need not be gone into any further, seeing that the Department has no funds. It would appear that unless by some happy, or unhappy, accident one arm of the service can be crippled in order to buy crutches for another, no money can ever be spared to effect the most valuable and most urgent of reforms. It is the old story; the army is starved in order that its parliamentary chiefs may not be bothered. That it is an old story is, perhaps, our one solitary consolation; for in spite of the traditional block at the War Office and the everlasting parsimony of Parliament, we have managed to pull through somehow, though of late years not always with credit. Generals and officers with firm wills of their own have got what they wanted in the long run; and it is the business of men like Colonel HALE and Major BERESFORD, who have an excellent thing to recommend, to convince their superiors that they ought to get it. Some day they are sure to have it; though not, perhaps, until the requisition is written with gunpowder or blood.

In the matter of military telegraphy, however, we are happy to learn that England is not far, if at all, behind the great nations of the Continent. It is little less than a gross scandal that communication with our most important arsenals and fortified places is still maintained by such a very unsatisfactory appliance as the A B C alone. But in respect to operations in the field our equipment is excellent, and the signallers probably the best in Europe. Both are inadequate, however, to meet a great emergency; and although we have some very superior signalling instruments, those invented by Captain CARDEW, and a first-rate light cable, there are not enough of either; and we have not yet made up our minds whether they may or may not be relied upon for tactical purposes with a fighting army. Hitherto the telegraph has not found much favour for the greater operations of war, and its comparative failure in the German army in 1870-1 was a serious blow to its further development. In the years that have intervened other nations have, however, enlarged their telegraph equipments, and have organised a telegraph corps with every cavalry regiment for the purpose of erecting wires, and maintaining the communication of advanced guards, or for destroying or tapping the enemy's wires. Germany, with characteristic pedantry, still adheres to the Morse recorder, and generally to a perfectly ideal telegraph, or none at all. The next great war will probably cure her of this fancy. England has had actual experience in several little wars, and on more than one occasion has proved the tactical advantages of its field telegraph corps. She also enjoys the advantage of being foremost in all improvements in matters relating to telegraphy; and the friendly relations between the Post Office and the army have already borne fruit in supplying the latter with not only a considerable body of highly skilled telegraphists available for the superior duties of trunk lines, but also with a still larger number of men who would efficiently perform what may be called the regimental telegraph signalling. We are not competent to enter into the technical questions raised by Colonel HALE'S paper; but in regard to the main point, we are of opinion that no country is better able than England to determine the problem whether the telegraph can be made a perfectly trustworthy adjunct to a moving army in the face of the enemy.

Unless it is trustworthy under all conditions a telegraph might of course be worse than useless, for its failure, when other means of communication have been neglected, would be disastrous. It is probably the frailty, or supposed frailty, of the system as a whole, that inspires the responsible generals with apprehension. But the construction of the cables, nowadays, and the pattern of the instruments, are such that in reality render them as safe as some other warlike appliances in quite common use. A British field telegraph can go wherever the men can go, and keep its ground so long as they can keep theirs. Over long distances it is of course liable to be cut off by the emeny, but so, too, are messengers; and a comparison of speed leaves the advantage all on the side of the telegraph, even allowing for breakages and the time occupied in repairs. In many instances the cable can be erected, or buried, or submerged where orderlies could not travel, and where, consequently, communications might be kept up when other means would fail. For operations in the field it is hard to see where doubts can arise in respect to the utility of the telegraph if properly worked. In case of accident its functions can be performed by the usual method, and the commanding officers would be no worse off than they were without a telegraph to begin with. The only doubt in

Digitized by Google

our mind is the quality of the operators detailed for such duties. Civilians could not be trusted under fire; and this being the case a less skilful body of soldiers must of necsssity be employed. The danger is in supposing that a little knowledge will go a great way when the work is very light. Major BERESFORD it seems to us rather errs in that direction. It is true that none but highly skilled operators, mostly civilians, or semi-civilians, can deal with the traffic on a long trunk line in rear of an advancing army; but this traffic is of comparative unimportance, and is generally not as urgent as are the messages between sections of an army in battle. It may be hoped that an inferior operator would keep his head, in a double sense, under fire; but a better man would be far less likely to lose it. A case once came under our personal notice where the signaller, being an indifferent telegraphist, became utterly unable to read anything in consequence of a terrible accident which had happened near to him. All he could do was to keep on mechanically repeating his first brief message of the disaster. It may be confidently asserted that in that and any similar case on the field of battle the man will forget soonest who has least to forget.

We venture on this criticism because we rather fear that the military authorities, having the means of obtaining adequate telegraphic instruction for their men, are not as diligent as they ought to be in keeping them in good practice. This is of the utmost importance; for when the men begin young every bit of continuous practice they get is so much added to their usefulness. The confidence they will feel in themselves and inspire in others would amply repay the trouble taken with their training. Major BERESFORD relies greatly on the improved appliances for re-establishing field telegraphy in the estimation of British generals. No doubt he is right; but when the hour of trial comes the most splendid equipment will be worthless unless it is manned with expert signallers; and we doubt whether any ordinary regimental telegraphers at present can be called expert, although —and this is what we are dwelling upon—they could be made so if the proper steps were taken to keep them in regular practice. We have mentioned the A B C instrument. It is admirable for an emergency, seeing that anybody can work it. But to keep it as a permanent means of communication, as Major BERESFORD tells us it is at very many of our naval and military stations, is proof that the really useful instruments, for service in a campaign are sometimes neglected. The men employed to work these A B C's might just as well have been taught the Morse, and kept to it.

ELECTRICAL PHENOMENA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following will strengthen Mr. Neville's reply to "Leakage":—

Take an old incandescent lamp, and having suspended a pair of short wires from the platinum eyes, hold it for a few seconds between the top and bottom sides of a fast running belt. If, just after withdawal from the belt, the suspended wires be brought close to the disengaged hand, a smart shock accompanied by a spark will be experienced. This experiment cannot be performed with a new lamp, I fancy because there is no film of carbon deposited upon the interior of the bulb, and thereby no inner coating made for the miniature Leyden jar formed by holding an old lamp in the manner described, and of which the outer coating is the hand.

I have often obtained fine bright brushes of electrical discharge by holding a pin point close to the main driving belt of a works engine. Usually such discharges are quite audible, emitting a king of whizzing sound.—Yours, &c.,

F. HARMAN LEWIS.

5, Claremont-villas, Alpha-road, Millwall, May 23rd, 1887.

SUBMARINE CABLES TO THE COLONIES AND INDIA.

The paper given below was submitted by Mr. O C. D. Ross to the members of the late Conference, and contains certain views which have, perhaps, not been so much discussed as have other views. Still, we are unable to agree with Mr. Ross in his suggestions, and we may say that the 4s. tariff has been under discussion and negotiation ever since the Berlin Conference two years ago. With regard to the suggested new cables, a glance at a map giving existing cables shows that all the points referred to at which there is any trade whatever—except the Mauritius—are already supplied with cable communication. It is difficult to see why our Government alone, or in conjunction with the Colonial Governments, should be asked to provide £160,000 subsidy per annum when they can for less than half that amount get a 4s. tariff by agreement with existing lines. We are still of the opinion that of necessity the West Coast of Africa cable will be ultimately carried to the Cape, and no doubt the exigencies of business, aided by politics, will cause Madagascar and the Mauritius to be included in the cable system.—ED. *E.*

The subject of telegraphic communication between Australia and the United Kingdom was discussed at the Colonial Conference held on Wednesday, April 27, at which time the following suggestion was in the hands of Sir Henry Holland and of most of the colonial representatives. It perhaps originated the proposal of the tariff of 4s. per word.

The subject of telegraphic communication between the United Kingdom and Australia by an alternative route from that supplied by the Eastern Extension Telegraph Company is engaging the attention of the Colonial Conference, Sir H. Holland having called special attention to it in his opening speech at the Foreign Office on April 4th, on which occasion he pointed out that it is "impossible to overrate the value of our extensive submarine system, either from a political or commercial point of view." . . . . "In commercial transactions," he said, "there are few of any magnitude which do not involve the forwarding and receiving of telegraphic messages; and it is of great importance that the control of the telegraphs should be, as far as possible, in British hands, while it is of equal importance that the tariffs should be as low as it is possible to make them." To this he added that he wished to direct the attention of the Conference to, and requested the Australasian and Canadian members to favour H.M.'s Government with, their views on, a proposal to connect Canada and Australia by a cable (about 7,000 miles in length) from Vancouver's Island to some point in one of the Australasian colonies, although "a very strong case would have to be made out to justify H.M.'s Government in proposing to Parliament to provide a subsidy for maintaining such a cable in competition with the existing companies."

Now, whilst fully concurring in the great importance to Australia and New Zealand of an alternative route for the transmission of messages to and from this country and Europe at a less onerous tariff than that charged by the existing companies, we would venture to submit to the representatives of the colonies that their object would not be best attained by means of such a cable to Vancouver's Island, because in the first place the messages would have to pass from thence to Quebec, over 3,047 miles of land lines, subject to interruptions at times from accidents due to the inclemency of the seasons, and possibly at others from Indian, Fenian, or other mischievous raiders. The climate of Persia is probably less severe than that of the Rocky Mountains and Manitoba, and yet the following report was some years ago addressed to the India Office by the late Colonel Sir J. Champain, with reference to the Indo-European telegraph which runs through that country:—"During the past winter it was absolutely impossible to repair breaks on some of the sections in Persia, where wire, posts and all, were for some weeks buried under the snow." And again:—"During December the Persian lines only worked five days, and only seven days during January, the messages having to be forwarded by estafette." Again, there is a second very serious objection, which is, perhaps, equally fatal. The distance by cable from Quebec to Liverpool is 2,709 geographical miles, and the total distance from Liverpool to Sydney, *vid* Vancouver's Island, would be no less than 13,190 miles; so that if from thence the lines were continued "to India over the existing Australian land lines and through the Straits, with extensions to Aden and the Cape in one direction and to Hong Kong in the other" (as proposed by Mr. Henniker Heaton), the distance from Liverpool to India or Kong Kong would be increased to about 18,000 miles, and that to the Cape to about 22,000, which would render these extensions totally unremunerative, because they could not convey messages to Europe in competition with the much shorter routes with which that traffic is already supplied, the present charge to any part of India being only 4s. per word.

But a large traffic in messages is as essential to a cable company as passengers and goods are to a railway, and no one can question the enormous importance of adding the Indian traffic to that of Australia in any new scheme for an alternative telegraphic route, inasmuch as it would not otherwise be possible to introduce a favourable tariff. The number of messages passing over the cable, as well as the charge which must be made for their transmission, will be in proportion to the amount of commerce of the countries with which the cable communicates; and whilst the trade of Australia and New Zealand amounted last year to £119,000,000, of which one-half is with the United Kingdom, that of India, Ceylon, and the Straits Settlements amounted to £199,000,000. It may therefore be safely assumed that a cable which should combine the traffic derived

Digitized by Google

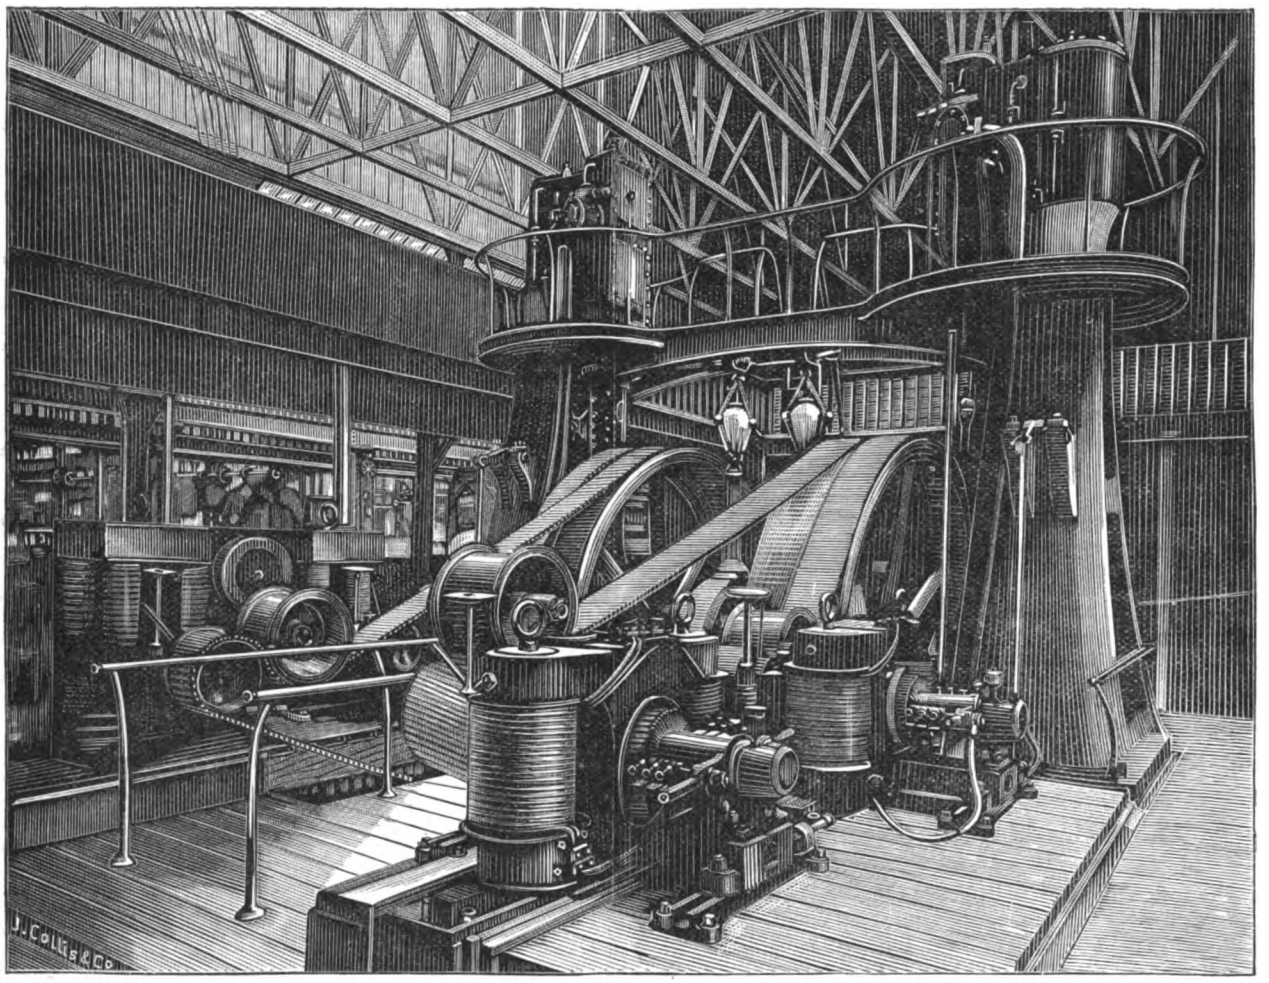
from Indian commerce with that from Australasia would permit of a far lower tariff being adopted than one which would carry only messages to or from Australia and New Zealand.

Now, it may be seen by a glance at the map that a series of cables with English stations throughout the whole distance might be laid from England to Australia *vid* the Cape, no single length of which need exceed 1,700 miles. Starting from Falmouth or the Land's End, such a cable would touch at a great many important points, viz., Gibraltar (1,050 miles), River Gambia (1,600), Sierra Leone (580), Ascension Island (1,000), St. Helena (720), the Cape (1,700), Natal (800), Mauritius (1,500), Chagos Archipelago (1,200), Ceylon (900), Singapore (1,600), and Exmouth Bay in Western Australia (1,000), from whence by the existing land lines it would connect with Melbourne (Victoria), Adelaide and Sydney, &c., and might be continued by an independent line to New Zealand (1,050 miles). With such a cable system, entirely controlled by one and the same company, a very much reduced tariff might be introduced—for at a charge per 1,000 miles of 3d. per word, the tariff to New Zealand (the most distant point) would be but 4s.; to Sydney or Melbourne, &c., 3s. 9d.; to Singapore, 3s. 3d.; to India, 3s.; and to the Cape, 1s. 8d.; against the corresponding 10s. 6d., 9s. 6d., 6s. 5d., 4s., and 8s. 11d., which are the respective prices now charged by the Eastern Telegraph Company. We need cite but one fact to show that such a tariff could not fail to be remunerative.

When the Atlantic cable was first established, our total trade with the United States (in 1865) was under £60 millions, as against the existing Indian and Australasian trade of £318 millions, but it produced during that year more than £400,000, or at the rate of, say, £1 for every £150 of trade, whereas, if we calculate the receipts from the Australasian and Indian trade at only one quarter of that proportion, or £1 for each £600 of trade, the receipts from the messages from the trade of India, the Straits, and Australasia at the above low scale of rates would amount to £530,000 per annum, and, deducting £80,000 a year for working expenses and reserve fund, there would remain a net balance of £450,000 wherewith to pay interest on the capital. This does not include the Cape trade or that of the many other stations on the African coast, which is considerable.

At £250 per mile, which since the fall in the value of copper is an ample price, the cost of laying these cables would be £3,500,000; and if, with a view to possible extensions, the capital of the cable company should be raised to £4,000,000, such earnings would provide a dividend at the rate of 11 per cent. per annum. When it is added that the Eastern Telegraph Company and the Eastern Extension Company have a combined capital of a good deal more than twice that amount—viz., £9,147,000, and that their united revenue amounted in 1886 to £1,178,000, it cannot but be admitted that our estimate is a very moderate one. It would be sufficient, however, that the Imperial or Colonial Governments should guarantee a minimum revenue of £160,000 per annum, in order that the requisite capital for laying such cables should be immediately raised without the least difficulty, and of that guarantee it is highly improbable that they would ever be called upon to disburse a single penny.

ELECTRIC LIGHTING AT THE MANCHESTER EXHIBITION.



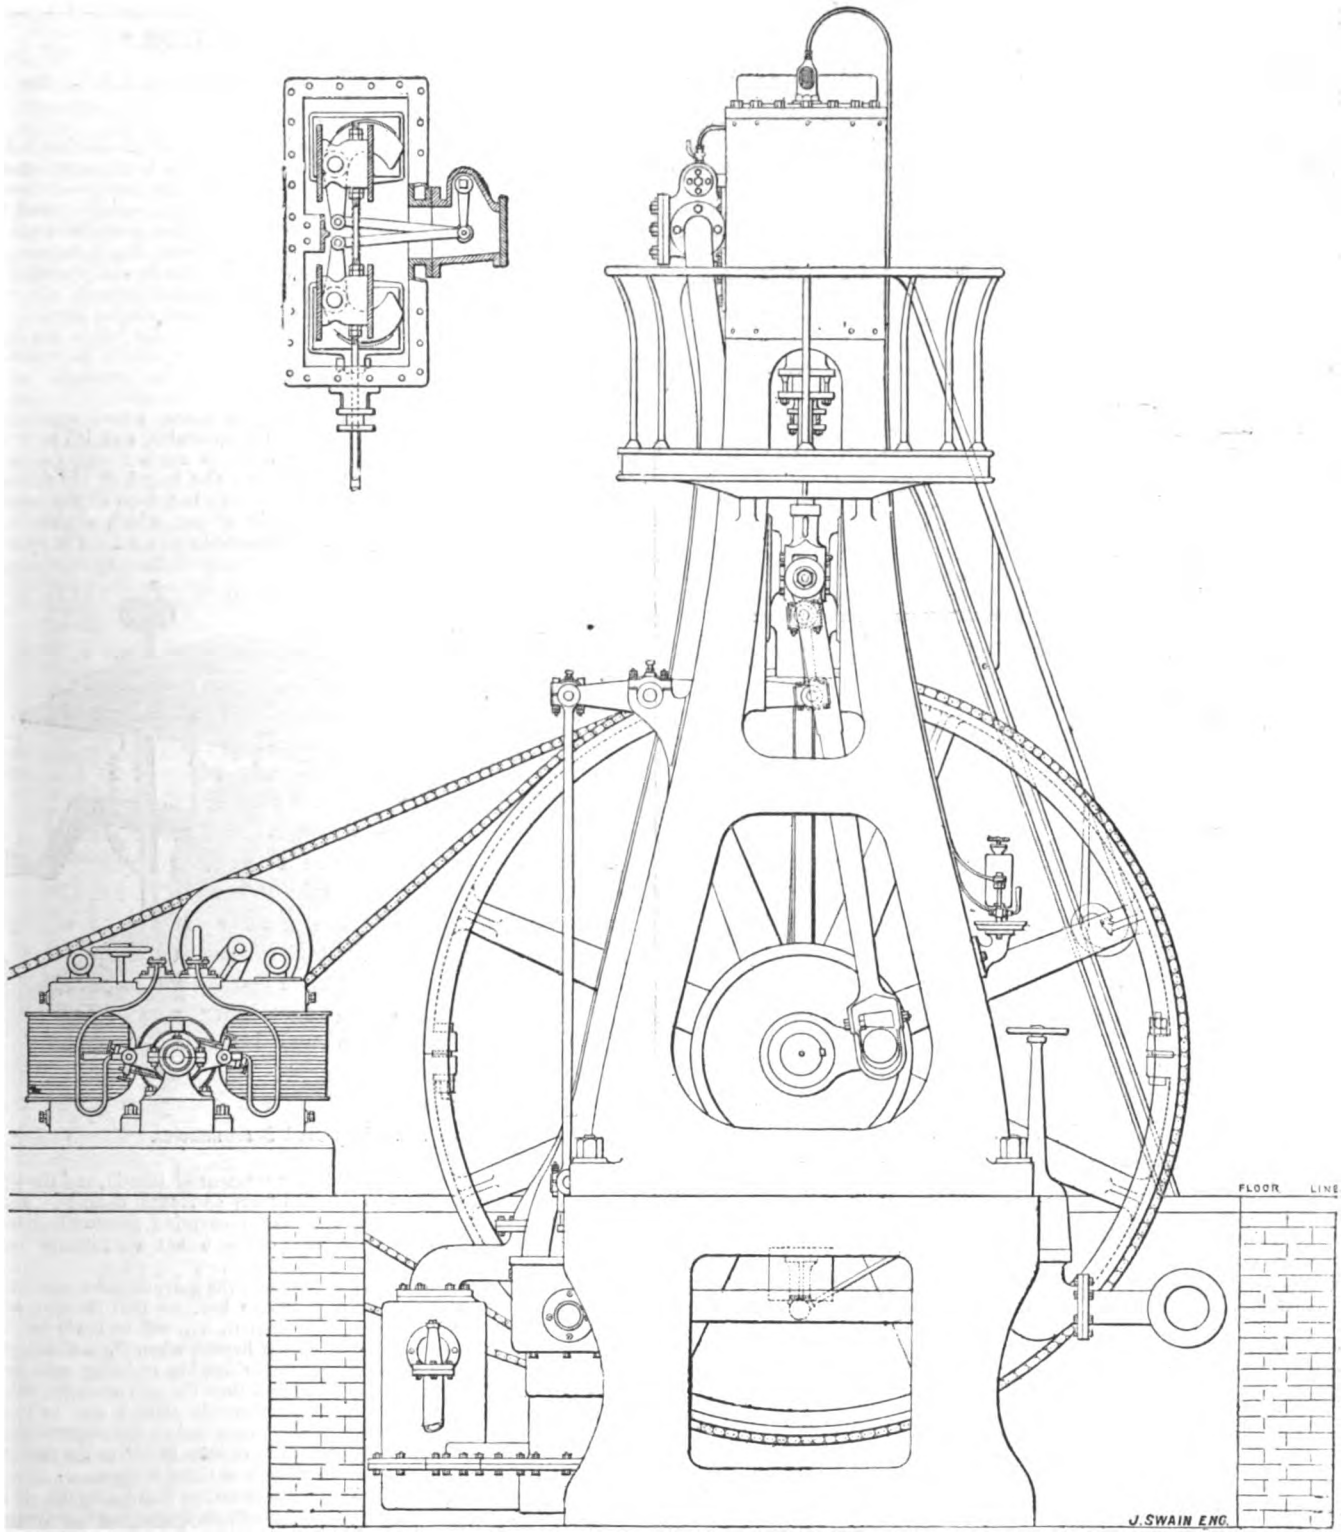
Messrs. Mather and Platt's Vertical Engines and Dynamos for Lighting the Fine Art Section of the Royal Jubilee Exhibition, Manchester, 1887.

The portion of the Electric Lighting Department adjoining the Machinery in Motion Section has been reserved for the electrical plant for lighting the Fine Art Galleries (14 in number), which are situated on the north side of the eastern nave. Both engines and dynamos have been constructed by Messrs. Mather and Platt, of the Salford Ironworks, Manchester. The engines have been specially designed for electric lighting work, and embody several interesting and novel features. In their general arrangement and in the method of driving Messrs. Mather and Platt have specially held in view the requirements of a central station installation, or a large mill installation, where economy of floor space is usually of primary importance. When the engines are worked to their full power, and the dynamos replaced by the next standard larger size, the whole plant would be capable of supplyin current for 4,000 lamps of sixteen candle-power, while the total floor space occupied does not exceed 30ft. by 20ft. Another essential condition of electric lighting engines is a sensitive, quick-acting automatic cut-off. This is accomplished by an entirely new form of cut-off valve recently patented by Messrs. Mather and Holgate, which is described below.

The engines, which we now illustrate, are of the vertical high-pressure condensing type, with a single inverted cylinder, 20in. diameter and 30in. stroke, intended to run at 120 revolutions per minute, and to work with a boiler pressure of 100lb., and under these conditions will each indicate about 200 horse-power. The two engines are entirely independent, each having a separate fly-wheel and independent off-bearings, but they are connected together by a bridge, to give access to the cylinders and valves. The cylinders, cylinder slide, and crank-bearing pedestal are cast in one piece, with the trunk or frame, which is of a box section, closed

Digitized by Google

entirely back and front, but open at the sides. The form is very rigid, and looks massive and substantial in design; at the same time, as the frame casting is only ⅜in. thick, it is actually not so heavy as it appears. The cylinder is fitted with a loose liner, which forms the steam jacket. The valve box is bolted on loose, and has double slide valves so as to get straight ports from the valve box to the cylinder. In the main slide valves the ports are straight on the cylinder side, but the passages are obliquely directed within the block of the valve, so that the ports on the off side are curved, the edges being circular. The main valves are worked in the usual way, with an excentric on the crank shaft. The cut-off valves work on the back of main valves, with a reciprocating motion, also derived from an excentric on the crank shaft. These valves have curved edges corresponding to the curvature of the ports of the main valves, and are carried on pivots fixed in the slide block. The cut-off valves can thus turn about an axis at right angles to the axis of the cylinder in addition to their rectilinear reciprocating motion. The point of the stroke at which the steam is cut off depends upon the angular position of the cut-off valve, which is regulated directly by the governor through a suitable series of levers. This form of cut-off has given exceedingly good results on smaller engines. Applied to an ordinary horizontal engine, indicating 20 horse-power, it was found that when 50 per cent. of the whole load was suddenly thrown off the momentary variation in speed did not exceed 4 per cent., which was immediately reduced to 1¼ per cent., and that with the *whole* load suddenly thrown off the rise in speed was 2½ per cent. only.



Scale ¾in. = 1ft.

The piston rod and crank pin are steel, and the connecting rod best hammered scrap. At the cross-head end the connecting rod is forked, and the wear taken up by a wedge and screw; its length is three times the stroke. The crank is of steel, and balanced and covered with a cast-iron shield. It is shrunk, and keyed on to the

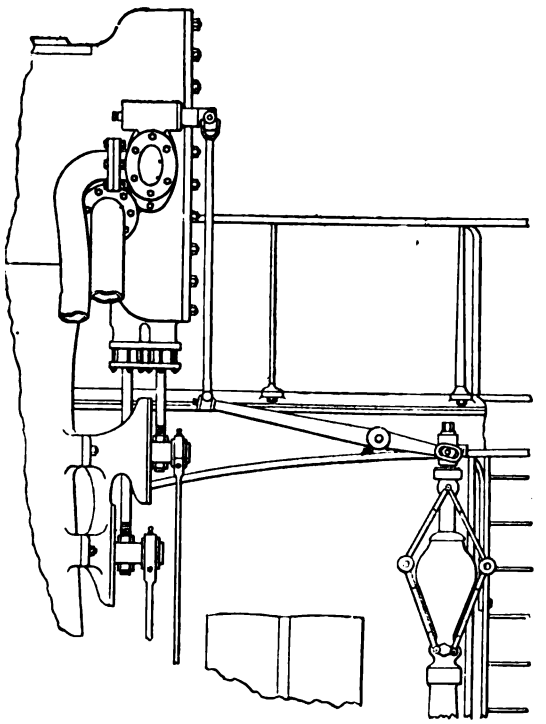
Digitized by Google

shaft; the crank pin is also shrunk in. The shaft is 8in. in diameter, bossed up to 8½in. for the fly-wheel, and at the crank end is carried in a bearing 15in. long, and at the off end in an angle pedestal 12in. long and 6½in. diameter. The main bearing is adjustable both top and bottom and at the sides by wedges and screws, so that the brasses can be fixed in any way while the engine is at work.

The fly-wheel is 12ft. diameter and 30in. wide, and is prepared for two 13in. belts. It was cast whole, split and bolted together at the rim, and held with bolts and shrunk hoops at the boss; its finished weight is 5¾ tons. All the bearings, the excentrics, crank pins, &c., are lubricated from one oil tank, to which the oil is pumped from a tank at a lower level, into which it collects from the drippers. The cylinder is lubricated by Mather and Platt's improved sight feed lubricator, requiring one plug valve only.

The air pumps and condenser are of the ordinary vertical type fixed below the floor. The pump is single acting, 12in. diameter, 15in. stroke, and is worked by a beam from the engine crosshead. Throughout, all threads on bolts are fine pitch or gas threads, and in working parts have a nut of ordinary depth, locked with a thin one, and in addition have a split cotter through the end of the bolt.

The left hand engine drives two Edison-Hopkinson dynamos, both shunt-wound for an output of 105 volts 320 amperes at a speed of 750 revolutions per minute, equivalent to 500 lamps of 16 candle-power. These machines have a commercial efficiency of 93·3 per cent., and an electrical efficiency of over 95 per cent.



Scale ¾in. = 1ft.

The improvement made in these dynamos by Dr. John Hopkinson and Messrs. Mather and Platt since the original Edison type is effectively shown by comparing the two smaller Edison-Hopkinson dynamos with the four Edison dynamos of the type which are at work close by. Although only about one-third the weight of the Edison dynamo the Edison-Hopkinson dynamos give a larger output and have a higher efficiency.

The right hand engine drives two Manchester dynamos, compound-wound, for an output of 100 volts 400 amperes, at a speed of 750 revolutions per minute, equivalent to 700 incandescent lamps of 16 candle-power.

The efficiency of the Manchester dynamo is also very high. With the full load the electrical efficiency is 94·8 per cent., and the commercial efficiency 92·8 per cent. These dynamos, as also the Edison-Hopkinson, are driven direct from the fly-wheels of the engines with link bolts. In order to increase the lap of the belt on the driving pulley of the dynamo it is bent on the slack side under a loose pulley riding on a stud carried on an arm projecting from the dynamo bed. This system of using a "jockey" pulley instead of a large belt is very effective when it is desirable to economise floor space. It was introduced by Messrs. Mather and Platt some years ago for dynamo driving, and has given good results. Careful experiments show that there is very little friction in the arrangement, and no undue wear of the belt.

The belts employed for driving the dynamo are worthy of notice, as, instead of having flat faces, as is usual with link belts, the section is double concave, so that the pins are not bent as the belt is bent over the convex surface of the pulleys. At the side of the vertical engines is a small double cylinder diagonal engine, driving a 20 horse-power Manchester dynamo. This is employed for generating the current, which is conveyed by cable to Messrs. Mather and Platt's exhibit in the Machinery in Motion Section, where a large ten-colour calico printing machine and an electrical singeing machine are driven by Manchester motors.

MODES OF MEASURING THE CO-EFFICIENTS OF SELF AND MUTUAL INDUCTION.*

By Profs. W. E. Ayrton, F.R.S., and John Perry, F.R.S., Members.

(*Continued from page 41.*)

Unless the glass tube in the secohmmeter described in our last issue be rather long, either the sensibility or the range of the instrument must be limited; but a very long straight tube would make the instrument inconveniently large, and a rapidly rotating *spiral* tube would probably break from centrifugal force acting on these parts of the tube that were not on the axis of rotation. Hence, in the latest form of secohmmeter, Fig. 6, we have been led to employ a *stationary* spiral glass tube, G, with its end cemented into a stationary hollow steel conical plug, fitting mercury-tight in the collar of the rotating metal box B, with its weighted elastic sides. This arrangement simplifies the tap mechanism, seen to the left in the figure, as the tap is not now rotating; also many small improvements have been introduced into this last form; for example, at all the joints there is mercury under pressure, so that there is no tendency for air to be drawn into the apparatus at the joints, a fault which sometimes occurred with the earlier form of the apparatus, and led to irregularities in the readings from a bubble of air in the box acting as an air spring, or from air in the glass tube altering the length of the thread of mercury. The temperature adjustment in this last form of the secohmmeter is made by screwing the screw S in or out, which slightly alters the volume of the stationary portion of the mercury vessel. The fly-wheel

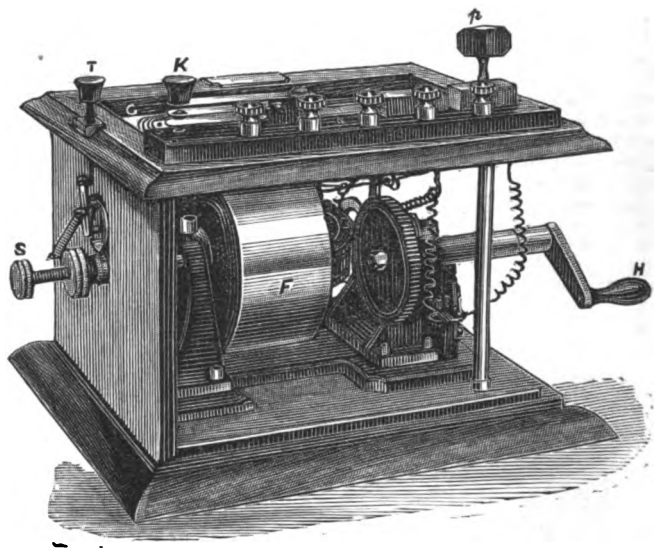


Fig. 6.—Improved Secohmmeter.

F has been made to have a much larger moment of inertia, and the box B is placed inside it, so as to be screened from accidental damage. Figs. 5 and 6 are similarly lettered, so that the description previously given of Fig. 5 refers equally well to those parts of Fig. 6 that are common to the experimental and the improved secohmmeter.

As both the wires from the battery and the galvanometer come to the secohmmeter, it is provided with a bridge key, so that the test of the ordinary resistance of the coil, electro-magnet, &c., can be made by using the same key as is used in putting on the battery when the self-induction experiment is being made. When the bridge key is being used in the ordinary way to first close the battery and then the galvanometer circuit, it is obviously necessary that the battery circuit should not be permanently broken nor the galvanometer short-circuited at the commutators of the secohmmeter, which may by chance have been left after the last experiment in a position which does one or both of these things.

Hence, when using the first form of the apparatus, Fig. 1, page 18, we were compelled to always make sure that the commutating arrangement was put in the right position when at rest before making the ordinary bridge test. Finding this, however, rather troublesome, the key in the instrument, Fig. 5, page 40, is made in the following special way:—In addition to the knob K, and the top-spring being able to be depressed, as on an ordinary bridge key, it can be moved sideways, and a cam and spring cause it to remain in one or other of two definite positions. When turned to the left, the commutators are cut out altogether, and the key acts as a simple bridge key, so that on being depressed it closes the battery circuit and then the galvanometer circuit; but when turned to the right, the commutators are

* Paper read before the Society of Telegraph-Engineers and Electricians on April 28th, 1887.

Digitized by Google

introduced, the one into the battery circuit, the other into the galvanometer short circuit, and the key now simply enables the battery circuit to be closed now and then, or kept permanently closed when balance is being obtained during the self-induction test.

In the last form of the instrument, Fig. 6, with the stationary spiral glass tube, the knob of the key has no side motion, and the connection of the commutating arrangement with the bridge or its disconnection from the bridge is effected by an auxiliary plug key, p; but Messrs. Nalder Bros, the makers of the secohmmeter, are rather in favour of a simple means of carrying out the method, which we used with the first form of the apparatus, of placing the commutating arrangement on the right position when at rest, and using an ordinary bridge key only.

Measuring very Small Coefficients of Self-Induction.

The first form of the secohmmeter was used during the autumn of last year for the measurement of rather small coefficients of self-induction which would be very difficult to measure by any other method, such as that of a straight piece of iron wire about 4 metres long, 3 millimetres in diameter, and having a resistance of 0·1 ohm. For such experiments a metre bridge was employed, $p+q$ (Fig. 2, page 19), being in this case the resistance of 100 centimetres of uniform platinoid wire, q being the resistance of n centimetres of this wire, and r the resistance of a German silver wire having a value of about 0·1 ohm. The following are a sample of the results obtained for the coefficient of self-induction of this iron wire referred to above:—

Revs. per Minute.	n for Balance.	Value of L.
0	50·00	
1200	50·55	0·0000244 secohms
0	49 97	
1620	50·70	0·0000237 ,,
1960	50 85	0 0000252 ,,
2750	51·20	0·0000257 ,,
0	49·90	

Mutual Induction.

After the instrument had been in use for some months for the absolute measurement of coefficients of self-induction, it occurred to us that just as the self-induction of a coil, S, could be made to act as if the resistance of the coil was increased by a definite constant amount, so the mutual induction of one coil, B, on another, S, could be made to act as if the resistance of S were increased by another definite amount the measurement of which would enable the coefficient of mutual induction to be determined by a *cumulative* test. Our idea was to place the coil S in one of the arms of the bridge, and first determine its coefficient of self-induction in the way already explained; then, in addition, to place the coil B in the battery circuit, and determine the change in the coefficient of self-induction of S, which would be of course due to the mutual induction of B on S. And the following rather long mathematical investigation, which Mr. Sumpner was good enough to carry out, at our suggestion, shows that this method of experimenting, as we anticipated, leads to an extremely simple formula or the measurement of the coefficient of mutual induction.

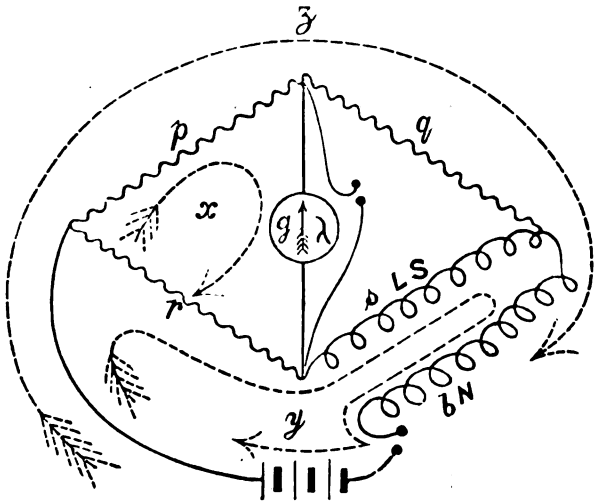

Fig. 7.

Fig. 7 differs only from Fig. 2 in that a coil of resistance, b, and coefficient of self-induction, N, has been introduced into the battery circuit, in addition to the coil of resistance, s, and coefficient of self-induction, L, which, as before, is in one arm of the bridge.

Let M be the coefficient of mutual induction of the coils on one another, then, if the battery circuit be closed and the galvanometer not short-circuited, the following equations hold true:—

$$p(x+z)+gx+\lambda\frac{dx}{dt}+r(x-y)=0 \quad . \quad . \quad . \quad . \quad (6)$$

$$p(x+z)+qz+b(y+z)+N\frac{d(y+z)}{dt}+M\frac{dy}{dt}=E \quad . \quad . \quad (7)$$

$$r(y-x)+sy+b(y+z)+(L+M)\frac{dy}{dt}+(M+N)\frac{d(y+z)}{dt}=E \quad (8)$$

Eliminating y and z from these equations we get

$$Ax+B\frac{dx}{dt}+C\frac{d^2x}{dt^2}+D\frac{d^3x}{dt^3}=Epo \quad . \quad . \quad . \quad . \quad (9)$$

where A, B, C, and D are functions of the resistances and coefficients of self and mutual induction, such that

$$A+Bu+Cu^2+Du^3$$

is identically equal to the determinant

$$\begin{vmatrix} (p+g+r+\lambda u) & p & -r \\ p & (p+q+b+Nu) & b+(M+N)u \\ -r & \{b+(M+N)u\} & \{b+r+s+(L+N+2M)u\} \end{vmatrix} \quad . \quad (10)$$

and where σ is the apparent increase of the resistance of the coil S, as determined by the change necessary to be made to obtain balance when the secohmmeter is rotated at a certain speed, balance having been previously obtained when the secohmmeter was at rest; or, in other words,

$$p(s+\sigma)=qr$$

when the secohmmeter is being rotated at this certain speed.

Then, in accordance with the plan adopted in the solution of the original problem (see page 19), we may divide the effect on the galvanometer into two portions, the one produced from the closing of the battery circuit to the short circuiting of the galvanometer, occupying a time T, the other taking place during the short-circuiting of the galvanometer, occupying a time T′ − T. If Q_1 be the quantity of electricity that passes through the galvanometer in the first interval, Q_1 may be obtained from the following equation obtained from integrating (9) from t equal nought to t equal T:—

$$AQ_1+B(x_T-x_0)+C\left\{\frac{dx}{dt_T}-\frac{dx}{dt_0}\right\}+D\left\{\frac{d^2x}{dt^2_T}-\frac{d^2x}{dt_0^2}\right\}=Epo\,T \quad (11)$$

where the suffix T or 0 after any expression decides the value to be given to t in the expression.

Following a similar train of reasoning to that employed in the original investigation, we find from equations (6), (7), and (8) that

$$x_0=o, \quad y_0=o, \quad z_0=o,$$

$$\frac{dx}{dt_0}=o \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

$$N\frac{dz}{dt_0}+(M+N)\frac{dy}{dt_0}=E,$$

$$(M+N)\frac{dz}{dt_0}+(L+N+2M)\frac{dy}{dt_0}=E,$$

and by differentiating (6) and using (12) we have

$$p\frac{dz}{dt_0}+\lambda\frac{d^2x}{dt_0^2}-r\frac{dy}{dt_0}=o.$$

From these we can deduce that

$$-\lambda\begin{vmatrix} N & M+N \\ M+N & L+N+2M \end{vmatrix}\frac{d^2x}{dt_0^2}=\{p(M+N)+rM\}E.$$

This, by (10), is equivalent to

$$-D\frac{d^2x}{dt_0^2}=\{p(M+N)+rM\}E.$$

We have next to consider the values of the expressions when t equals T, which time we assume to be long enough for the currents to become steady, therefore

$$x_T=\frac{Epo}{A}, \quad \frac{dx}{dt_T}=0, \quad \text{and} \quad \frac{d^2x}{dt_T^2}=0,$$

so that, substituting the values of the various expressions in (11), we have

$$AQ_1+\frac{B}{A}Epo+(L+\frac{p+r}{p}M)Ep=Epo\,T \quad . \quad . \quad (13)$$

At the time T the galvanometer is short-circuited and the current in the galvanometer dies away, following the law

$$gx+\lambda\frac{dx}{dt}=0;$$

so that if Q_2 is the quantity that passes through the galvanometer from t equals T to t equals T′, T′ − T being the time during which the galvanometer is short-circuited,

$$gQ_2+\lambda(x_{T'}-x_T)=0;$$

and

$$x_T=\frac{Epo}{A},$$

also

$$x_{T'}=0,$$

since, by hypothesis, T′ − T is long enough for the current to die away in the galvanometer;

$$\therefore Q_2=\frac{Epo}{A}\cdot\frac{\lambda}{g}$$

And since for no deflection of the galvanometer needle we must have

$$Q_1+Q_2=0,$$

it follows that

$$AQ_1=-Epo\frac{\lambda}{g},$$

and equation (13) reduces itself simply to

$$L+\frac{p+r}{p}M=\sigma\left(T+\frac{\lambda}{g}-\frac{B}{A}\right). \quad . \quad . \quad . \quad . \quad (14)$$

an equation only differing from equation (4), page 20, the result obtained in the original investigation, by the addition of the term

$$\frac{p+r}{p}M,$$

depending on the coefficient of mutual induction. And since, as will be shown later on, $\frac{\lambda}{g}-\frac{B}{A}$ is small compared with T, just as it was in the

Digitized by Google

original investigation, we have approximately

$$L+\frac{p+r}{p}M=\sigma T \text{ secohms},$$

which, as before, may be written as

$$L+\frac{p+r}{p}M=\frac{60\,l}{N}\sigma \text{ secohms} \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

where l is the lead in the secohmmeter, and N the number of revolutions per minute which cause an apparent increase of resistance σ ohms of the coil S.

To make, therefore, the complete test for determining the coefficient of self-induction, L, of the coil S, and the coefficient of mutual induction, M, between it and any other coil, we first exclude the other coil from the battery circuit, as shown in Fig. 2, page 19, and determine L in the manner already described. We next include the other coil in the battery circuit, as shown in Fig. 7, and repeat the experiment with this secohmmeter, then

$$M=\frac{p}{p+r}\left(\frac{60\,l}{N}\sigma-L\right),$$

or, if N_1 and σ_1 are the speeds and apparent increase of resistance in a first experiment, and N_2 and σ_2 in a second, we have

$$L=60\,l\,\frac{\sigma_1}{N_1}$$

$$M=\frac{p}{p+r}60\,l\left(\frac{\sigma_2}{N_1}-\frac{\sigma_1}{N_1}\right) \quad . \quad . \quad . \quad . \quad . \quad (16)$$

We have stated above that $\frac{\lambda}{g}-\frac{B}{A}$ is generally small compared with T, and to ascertain the value of $\frac{B}{A}$ in (14), in order to investigate this, we may write

$$\frac{B}{A}=\frac{B_1}{A}\lambda+\frac{B_2}{A}L+\frac{B_3}{A}M+\frac{B_4}{A}N;$$

then it is easy to show that

$\frac{A}{B_1}=g+$resistance of network between the extremities of g, supposing g removed,

$\frac{A}{B_2}=s+$resistance of network between the extremities of s, supposing s removed,

$\frac{A}{B_4}=b+$resistance of network between the extremeties of b, supposing b removed,

$\frac{A}{B_3}=\frac{1}{2}$ the ratio of the value of an E.M.F. inserted in the branch s, to the steady current set up in the battery branch, b, by this E.M.F. in s.

Writing r_g, r_s, r_b for the three resistances represented by $\frac{A}{B_1}$, $\frac{A}{B_2}$, and $\frac{A}{B_4}$ respectively, and r_{bs} for the ratio of the E.M.F. in s to the current produced by it in b, equation (14) becomes

$$L+\frac{p+r}{p}M=\sigma\left(T+\frac{\lambda}{g}-\frac{\lambda}{r_g}-\frac{L}{r_s}-\frac{N}{r_b}-\frac{2M}{r_{bs}}\right) \quad . \quad (17)$$

If g is as large or larger than the resistances of any one of the arms of the bridge, $\frac{\lambda}{g}-\frac{\lambda}{r_g}$ will be very small. $\frac{\sigma}{r_s}$ is generally small compared with unity, and therefore $\frac{\sigma}{r_s}L$ can be neglected in comparison with L, so can $\frac{2\sigma}{r_{bs}}M$ in comparison with $\frac{p+r}{p}M$.

There remains the term $\frac{\sigma}{r_b}N$. If N be very large, then will b also be very large, and as r_b is much larger than b, while σ will be much less than b if b be large, it follows that the term $\frac{\sigma}{r_b}N$ can also generally be neglected; hence the approximate formula (15) will usually be accurate enough for practical purposes. And the value of any one of the last three fractions in the bracket in (17) can be made as small as we like, by adding resistance without self-induction to s or to b, a precaution that it is desirable to adopt if it be feared that any one of these three fractions is not negligible in comparison with T.

(To be continued.)

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis :—

ON THE MIGRATION OF IONS AND AN EXPERIMENTAL DETERMINATION OF ABSOLUTE IONIC VELOCITY.

BY DR. OLIVER LODGE.

(Continued from page 526, Vol. XVIII.)

The following abbreviated excerpts from Laboratory Note-books will sufficiently illustrate the results so far attained.

Specific Gravity Data.—11·73 grammes of crystallised baric chloride added to 88·27 grammes of water give a solution of sp. gr. 1·095, containing about 10 per cent. of the salt itself. One-thirtieth of its bulk of water added reduces it to 1·093. 22·68 grammes of crystallised sodic sulphate added to 77·32 grammes of water give a solution of specific gravity 1·093, likewise containing about 10 per cent. of the salt itself. 19·98 grammes of hydrochloric acid added to 80·02 of water make sp. gr. 1·098, and is a 25 per cent. solution. This also was reduced to 1·093.

Experiment made of inverting a test tube containing one of these liquors into a pneumatic trough containing another. In each case pretty rapid mixture resulted.

The hydrochloric acid solution was then diluted with an equal volume of water, making its sp. gr. 1·030. A test tube was filled with this and inverted over the baric chloride solution. There was no visible mixture; the place where the two liquids meet remained quite sharp.

October 30, 1885.—A tube of uniform cross section and ·41 centimetre internal diameter was taken and bent as shown in Fig. 2. Its total length was 84·2 centimetres. This tube was marked No. I.

It was filled with hydrochloric acid solution, of specific gravity 1·030, slightly tinged with litmus.

Two vessels containing the 1·093 solution of Na_2SO_4 and $BaCl_2$ respectively were arranged with vertical sticks of electric light carbon as electrodes, and their levels as carefully adjusted as possible. The final adjustment was performed by a short siphon tube with a pinch-cock in the middle, and full of hydrochloric acid of sp. gr. 1·093 (see Fig. 3). The experimental tube No. I. was then introduced very carefully at xiv. hrs. 58 min. At xv. hrs. 2 min. the pinch-cock of the levelling tube was closed, and the current started, flowing from $BaCl_2$ vessel to Na_2SO_4 vessel. Current strength ·01 ampere.

October 31.—Noon: ring beginning to form.

22 centims. from Na_2SO_4 end, and
62·2 ,, ,, $BaCl_2$ end.

November 2, 1885.—Another similar experiment with same tube. Levelling tube started at xi. hrs. 49 min. Experimental tube put in xi. hrs. 55 min. Levelling tube closed at xii. hrs. 2 min., and current started of strength ·01 ampere.

By November 3, at ix. hrs. 47 min., ring formed; and at xiv. hrs. the current was stopped. Strength, ·007 ampere.

Solutions then tested and found all right; apparently a satisfactory experiment.

Distance of ring
from Na_2SO_4 end 24·6;
,, $BaCl_2$,, 59·6.

November 3.—Another experiment started with the same tube; fresh liquids still with density 1·093 for $BaCl_2$ and Na_2SO_4, the HCl (coloured with litmus) of density 1·030. Levelling tube put in at xiv. hrs. 30 min.; experimental tube at xiv. hrs. 34 min. Levelling tube closed and current started at xiv. hrs. 36 min. Strength of current ·009.

On November 4 at x. o'clock the ring was formed.

Distance from Na_2SO_4 end 31·8 centims.
,, $BaCl_2$,, 52·4 ,,

November 4.—Similar experiment, except that the tube is filled with an uncoloured solution of HCl of ordinary testing strength—that is, one centigramme molecule in 5 cc. Average current strength, ·009.

Distance of ring from Na_2SO_4 end 16·8 centims.
,, ,, $BaCl_2$,, 67·6 ,,

November 6.—Another experiment with the ·01 HCl is 5 cc. Current strength, ·009.

Distance of ring from Na_2SO_4 end 16·4;
,, ,, $BaCl_2$,, 68·0.

November 7.—A blank experiment arranged purposely with no current. Tube put in and levelling tube closed at xiii. hrs. 35 min.

By November 16 *there was no ring formed and no deposit anywhere in the tube.*

November 24.—Two other similar tubes prepared, each of the same internal diameter—·41 centims.—but of lengths. No. II. 87 centims., No. III. 88·4 centims. The three tubes were then filled with the HCl solution (·01 in 5 cc) and arranged with three pairs of vessels in multiple arc. The result was that, while the precipitate occurred in tube I. in about its usual position, in tubes II. and III. it occurred quite at the end of the tube where it dipped into the Na_2SO_4 vessel, and accordingly most of it fell out of the tube.

December 1.—Another experiment started; tubes I. and II. as before, but a layer of paraffin over the vessels of tube III., and a siphon levelling tube full of paraffin dipping into it and left open, as shown in Fig. 4. The current strength decreased steadily from ·01 to ·005.

In tube II. the chief precipitate occurred again close to the Na_2SO_4 end.
In tube I. the distances were 16·5 centims. from Na_2SO_4 end.
67·8 ,, Ba_2Cl end.
In tube III. they were 20·2 ,, Na_2SO_4 end
68·3 ,, Ba_2Cl end

Precipitates appeared on Dec. 3.

December 3.—Paraffin levelling tubes now provided for both tubes II. and III. The ring formed well in all three now, and quite blocked the tube. The distances were—

In tube I.	15 centims.	from	Na_2SO_4 end.
	69	,,	$BaCl_2$.
In tube II.	21	,,	Na_2SO_4 end.
	66·4	,,	$BaCl_2$ end.
In tube III.	21·5	,,	Na_2SO_4 end.
	66·7	,,	$BaCl_2$.

Current strength in each tube about ·01 ampere.

Digitized by Google

December 5.—Same experiment repeated with 22 cells, tube I. being the only one without paraffin. The distances were—

	I.	II.	III.
From Na_2So_4 end	16·1	22·2	22·2
From $BaCl_2$ end	67·6	64·8	66·1

Current strength about ·015

December 5.—The same experiment repeated, but with only 3 cells. By December 9 a ring had formed in II. and III., but not in I.

Distances of ring—

In tube II. { 25·9 from Na_2SO_4 end. / 60·9 from $BaCl_2$ end.

In tube III. { 27·1 from Na_2SO_4 end. / 60·9 from $BaCl_2$ end.

Current strength in each tube about ·002 ampere.

Experiments with tubes of different bore.

Two fresh tubes were prepared, Nos. IV. and V., of about the same length, but smaller in bore than the first three, No. IV. being about ·3 centim. diameter and No. V. about ·22.

(For more accurate gauging of all the tubes see below.)

December 9.—Two tubes, Nos. II. and V. arranged in series; two other tubes, Nos. III. and IV., also arranged in series, and the current from 16 secondary cells allowed to divide between the two pairs, starting at 4 p.m. on December 9.

Current strength in tubes III. and IV. decreasing from ·0075 to ·0035; in tubes II. and V. from ·005 to ·0012.

By December 11, 10 A.M., a ring was almost completely formed in tube IV., fairly so in V., an indication in III., and nothing in II. By December 12 a ring formed in tube III., and by December 14 it was beginning also in tube II.

December 14 the state of the tubes was sketched thus :—

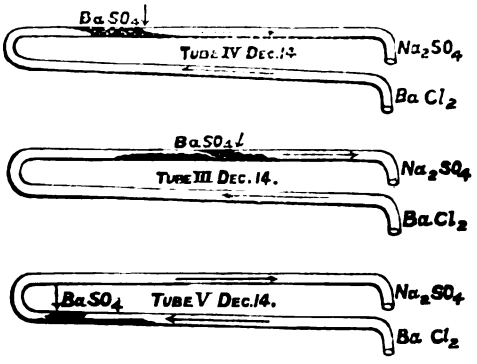

FIG. 5.

On the 15th the state of tube II. was this :—

FIG. 6[1]

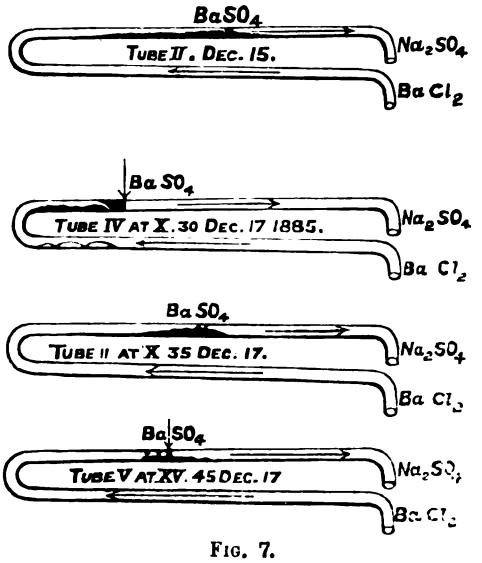

FIG. 7.

An arrow marks the place of first appearance of the ring.

The distances are as follows :—

	II.	III.	IV.	V.
Distance from Na_2SO_4 end	19·0	17·5	30·5	45·8
,, $BaCl_2$ end	66·7	69·5	54·7	40·7

December 15. 7 *p.m.*—Vessels same as in last experiment, but tubes arranged II. and IV. in series, one pair, and III. and V. in series the other pair.

Current strength in II. and IV. from ·0095 to ·0044; and in III. and V. from ·0062 to ·0022.

By December 16, 4 P.M., deposit showing itself in tube IV.

December 17, 10 A.M., ring formed in tube IV., and almost complete in II. An indication in V. By 3 P.M. the ring in V. was complete, and a slight deposit in tube III.

On December 20 ring complete in III., and current stopped.

Distances of ring when first formed—

in tube	II.	III.	IV.	V.
from Na_2SO_4 end	21·5	17·1	28·6	24·3
,, $BaCl_2$ end	64·5	69·8	56·4	62·2

Gauging of the tubes.

January 6, 1886.—Determined bore of tube by filling them with mercury at 12° C.

——	I.	II.	III.	IV.	V.
Length in centims.	82·5	85·7	87·3	85·4	86·3
Weight of mercury filling tube, in grammes	157·0	161·5	157·92	113·4	56·65
Calculated volume	11 6	2 0	11·7	8·4	4·2
Sectional area	·14	·14	·134	·0983	·0487
Diameter of bore	·423	·423	·404	·355	·25

January 7.—Experiment with all four tubes in multiple are, two of them dipping into the same pair of vessels; the solutions of Ba_2Cl_2 and Na_2SO_4, weaker than before, viz., sp. gr. 1·050, because in the cold weather the sulphate of soda was apt to crystallise out of the old solutions. Current started at 5 P.M., 20 cells. By January 9, 9 A.M., rings were formed in tubes II., III., and IV. No ring in V., but some air-bubbles had collected in it, and apparently stopped its current. The rings in II. and IV. were beautifully sharp.

	II.	III.	IV.
Distance of ring from Na_2SO_4 end	17·0	6·5	16·9
	68·7	80·8	68·5

January 9.—Another similar experiment, but with 15 cells. By the morning of January 11 rings were formed in 3 tubes, and one was forming in tube V.

	II.	III.	IV.	V.
Distance from Na_2SO_4 end	26·5	10·4	21·0	33·7
,, $BaCl_2$ end	59·2	76·9	64·4	52·6

January 22.—A precisely similar experiment, except that 20 cells were applied. By January 23 (evening) rings were forming in three of the tubes, but there was an air bubble again in V.

	II.	III.	IV.
Distance of ring from Na_2SO_4 end	34·3	22·3	24·4
,, ,, $BaCl_2$ end	51·4	65·0	61·0

February 1.—Similar experiment.

	II.	III.	IV.	V.
Distance from Na_2SO_4 end	38·2	30·6	26·2	23·1
,, ,, $BaCl_2$ end	47·5	56·7	59·2	63·2

So far the data are not satisfactory. There is a decided consensus in favour of the more rapid travelling of Ba than of SO_4, but no estimate of the ratio of the velocities can be relied on. The average makes Ba travel 3·2 times as fast as SO_4.

Experiments on jelly-filled tubes.

Four new tubes were made of dimensions and numbers here specified :—

Number	VI.	VII.	VIII.	IX.	
Length	86·6	88·3	84·8	103·8	centims.
Diameter	·327	·460	·476	·825	,,

A gelatine solution was made by dissolving 20 grammes of gelatine in 150 cc. of dilute acetic acid of ordinary testing strength, viz., 1 centigramme molecule per 5 cc., the tubes filled and allowed to go solid. The tubes were arranged in multiple arc with a galvanometer able to be switched at pleasure into the circuit of each. The solutions in the vessels were $BaCl_2$ and Na_2SO_4, as before.

February 13.—The E.M.F. of 24 cells was applied to these four new tubes at noon, and readings of the current (which was very weak) taken at intervals.

It was found that something in travelling from the anode vessel (presumably the Ba) rendered the jelly turbid, and that the turbidity, being sharply defined, served as an indication of the distance to which this ion had reached. Marks were accordingly made on the tube to fix its position at different times, the distances of these marks from the end of the tube being afterwards measured. After a time the SO_4, travelling from the other end, met the Ba and precipitated a sharp ring of $BaSO_4$, whose position was noted. The current was not stopped, however; it was left on to see at what rate the precipitation advanced, and whether it advanced in both directions or in only one. In the free liquid HCl tubes it had seemed only to advance in the direction opposed to the current, viz., towards the $BaCl_2$ vessel. It was now observed in these jelly tubes to widen out both ways, but faster towards the $BaCl_2$ vessel than towards the Na_2SO_4.

It was specially noticeable that in these jelly tubes the disc of $BaSO_4$, indicating the meeting of the ions, was formed near the middle of the tube, instead of much nearer the Na_2SO_4 end, as it had done in free liquid. Thus while Ba travelled 41·1 cm. to the meeting-place, SO_4

Digitized by Google

travelled 45·5, in tube No. VI. In the tube No IX. Ba travels 47 8, while SO_4 travels 56·6, and so on ; see following table.

SUMMARY OF EXPERIMENTS ON TRAVELLING OF BA THROUGH FOUR JELLY TUBES.

(To be continued.)

FIFTY YEARS' PROGRESS IN TELEGRAPHY.*

By W. H. PREECE, F.R.S., Vice-President of the Society.

(Concluded from page 43.)

SNOWSTORMS.

We have been subject, at long intervals of ten years, to serious and destructive snowstorms, which have seriously damaged our overground wires. The wires constructed and maintained by the Post Office did not suffer very seriously, but those maintained along the railways out of London, and erected by the Telephone Company overhead, were severely handled by the elements. In fact, in London, many unrepaired telephone wires are still seen dangling over the housetops. No accident to person has been recorded, but the very serious interruption to communication has raised earnest attention to the necessity of putting more wires underground. It has always been the practice of the Post Office to do this in London and large cities, but not only the excessive cost, but the diminished speed of working, has hitherto prevented its being done to any large extent in the country. The Postmaster General has now under his consideration a scheme for doing this more generally, and there is nothing whatever to prevent this being done by the telephone companies. In fact, in many cases, telephones work better underground than overhead. The laws that govern the transmission of speech are now thoroughly known, and the fancied difficulties in using underground wires have vanished into thin air.

In London alone we have 255 miles of pipes, containing 10,212 miles of wire. In fact, all our great trunk lines are out of danger of stoppage from storms. We have 868 miles of open wire included within the metropolitan area, but these are chiefly in the suburbs, and include long outlying sections, used either for police or fire brigade wires, or for private persons.

There are 213 offices in London now served wholly by buried wires. It will be seen, therefore, that the Post Office has been fully alive to the drawbacks attending the existence of overhead lines in crowded centres. It is steadily pursuing the same policy, and although some open wires must exist if telegraphs are to exist at all in certain localities, still the overhead proportion, as compared with the underground, steadily diminishes.

* Paper read before the Society of Arts, on Wednesday, May 18.

Comparative Return, showing the Mileage of Line and Wire in the United Kingdom.

Year.	Overhead.		Underground.	
	Line.	Wire.	Line.	Wire.
	Miles.	Miles.	Miles.	Miles.
1877	23,766¼	101,627¼	394¾	8,013¾
1878	24,438¾	102,074	445¾	9,023
1882	25,001½	111,811¾	478¼	10,993¼
1886	26,425	150,590	677¼	19,605

To provide a scheme extending throughout the kingdom to connect only the more important towns, and uniting those towns by less than half the existing number of overhead wires, would cost something like £2,500,000, and in these days of attenuated exchequers such an outlay is very serious to incur, although it may effectually guard against stoppages ranging from three days to three weeks, once in ten years or so.

TELEPHONES.

In 1877, a most striking departure in telegraphy was made by Prof. Graham Bell in America, who showed that it was possible to reproduce for commercial purposes the human voice at great distances. The telephone sprang into existence almost perfect in its action, and with the improvement immediately afterwards introduced by Mr. Edison and Prof Hughes, it has leapt into existence with giant bounds. In America there were on December 31, 1886, 353,518 telephone receivers and microphone transmitters in use and under rental. The total number of subscribers to exchanges is 147,068. In Europe the number is very great. The number of exchanges in England is 184 ; there are 19,784 subscribers, but there are 101,000 telephones in use as royalty-paid receivers and transmitters.

Stockholm has shown a remarkable development. With a population of 210,000—about the size of Edinburgh—there are over 5,000 subscribers to the exchange, while in Edinburgh there are only 372.

PNEUMATIC TELEGRAPHS.

The Electric Telegraph Company introduced, in 1854, a pneumatic tube of lead protected in iron pipes, between their central station in Lothbury and the Stock Exchange, by which the messages themselves, in small leather carriers, were drawn through by a vacuum. The system proved so economical and rapid that it was extended in the City of London, Glasgow, Liverpool, and in Manchester.

At the transfer there were altogether 2 miles 1,625 yards of pipes laid down, but now there are in :—

London	32	miles,	1,209	yards.
Birmingham	0	,,	917	,,
Liverpool	5	,,	1,593	,,
Newcastle	0	,,	1,204	,,
Glasgow	1	,,	768	,,
Dublin	1	,,	1,013	,,
Manchester	2	,,	233	,,
Total	44	miles,	1,737	yards.

The longest tube is that between the central station, General Post Office, and the House of Commons (3,859 yards), through which 700 messages are sometimes sent, each carrier taking about six minutes per journey, but intermediate signallers being employed, carriers can be despatched every two minutes. In most cases there are two tubes, one for sending and the other for receiving—through one the messages are blown, through the other they are sucked—the engines and pumps being in all cases in the central station. At the time of the transfer the engine power employed was as follows :—

	Engine.	h.-p.
London Telegraph Station	1	20
Birmingham	1	6
Liverpool	1	8
Manchester	1	10
Glasgow...	1	6
Total nominal horse-power.....		50

The engine power employed at present is as follows :—

London :—St. Martin's-le-Grand—Condensing engines. (3 are working and 1 spare)	4	each	50
Liverpool—Condensing engines. (2 are working and 1 spare)	3	,,	30
Manchester—(1 of which is working and 1 spare)	2	,,	10
Birmingham	1	,,	6
Glasgow	1	,,	20
Newcastle-on-Tyne.....	1	,,	8
Dublin—(1 of which is working and 1 spare).....	2	,,	10
	14	...	134

This gives a total of 14 engines, and a total of 354 nominal horse-power for working the 112 pneumatic tubes now in use.

CABLES.

The exclusion of private enterprise from telegraphic undertaking in these islands does not apply to our colonies and to the ocean. The growth of

Digitized by Google

submarine telegraphy has been enormous. We read in our newspaper every morning the previous day's doings in every quarter of the world. *The Times* of May 16 had two and a-half columns from Philadelphia, one and a-half column from India, a despatch from Natal, another from Melbourne, and news from every capital in Europe.

In 1851 two or three far-seeing individuals, prominent among whom was our own vice-president, Mr. T. Crampton, risked their capital in laying a cable between Dover and Calais. Now there are 112,673 miles of submarine cable resting on the bottom of the ocean, which has absorbed a capital of £37,000,000. Appendix IV. gives a list of them.

No less than nine cables cross the Atlantic. All our important colonies are in connection with London—the heart of the world. Laying and repairing has become a simple and a certain matter in any depth and in every sea. A whole fleet of ships—over thirty—are maintained for the purpose. Submarine telegraphy has become a solid property—the main result of British skill or British enterprise—unaided by Government support. The apparatus used is principally Sir William Thomson's recorder.

Railways.

The monopoly which the Postmaster-General possesses regarding telegraphy only applies to message-carrying for profit—it does not apply to those numerous wires that are required for the protection of life on railways. Each of our large railway companies has a distinct telegraph system of its own, employing a very large staff, and used for the purpose of regulating its own traffic. There are about 80 000 miles of wire erected for the purpose, and probably 20,000 various kinds of instruments in use. The apparatus used for telegraphy is invariably the needle, though generally on the wires connecting the Post Office sounders are employed. The apparatus used for block working is very various. Every great railway out of London has a different system. The survival of the fittest has not yet asserted itself. But they all work well, and without electric signalling the working of our railway system would be absolutely impossible.

Finance.

The financial position of the telegraph business is sound. The amount of capital debited against telegraphs is £10,140,000 ; of this, £7,000,000 was the purchase money, the rest has been expended in extensions and in furthering the business. If the trust which the Post Office undertook on behalf of the public were handed back to the care of private enterprise, we should hand over a going business drawing a gross revenue of nearly £2,000,000 per annum, and assets which may be estimated at £4,000,000. If financiers were willing to pay several millions for a single brewing business in Dublin, what would they pay for a grand Imperial monopoly, serving every town in the United Kingdom, and of which every person in these islands is a customer?

It is very much the fashion to decry the terms of purchase. Doubtless, the terms paid were very high, and the Post Office authorities who negotiated the purchase were unnecessarily hurried, and perhaps overmatched by the railway companies, for they had to pay twice over for certain privileges. Even Mr. Fawcett proposed to wipe out as wasted capital the excess paid for telegraphs, and to call it a bad debt. As the bargain stands the public have not been losers. A Government department cannot compete in economy with an ordinary commercial firm subject to competition; nevertheless, the business done pays a dividend on the capital expended. The balance of profit for the year ending 31st March, 1886, if our accounts were made out on commercial principles, was £160,000.

It is amusing, after this length of time, to read the arguments that were adduced against the absorption of the telegraphs by the State. Every reason has been proved wrong, every prophesy has remained unfulfilled. I can say this with a good grace, for I was one of the prophets.

The advantages of a State-controlled telegraph system have been amply fulfilled. There has been established a cheaper, more widely extended, and more expeditious system of telegraphy; the wires have been erected to districts that private companies could not reach; the cost of telegrams has been reduced, not only in their transmission but in their delivery; the number of offices opened has been trebled; a provincial and an evening press has been virtually created. Adam Smith said that the Post Office was the only kind of business that Government had always managed with success. We can now add telegraphy.

Appendix I.

Statement of number of Telegraph Offices open at the end of each year since the Transfer :—

	Post Offices.	Railway Stations.	Totals.

TACTICS AS AFFECTED BY FIELD TELEGRAPHY.

Two interesting papers on "Field Telegraphy" were read by Colonel L. Hale, R.E., and Major C. F. Beresford, R.E., at the meeting of the United Service Institution on the 20th inst., abstracts of which are given below:

In the course of his remarks, Colonel LONSDALE HALE said it was an accepted fact that the successful conduct of the operations of strategy was greatly facilitated, and in some cases only rendered possible by the existence of telegraphic communication between the supreme strategical leader and his subordinates, and some little time ago it occurred independently to some of his brother officers immediately connected with the telegraphic work of the corps and to himself that if, in the operations of tactics the same kind of communication existed, similar advantages would be gained, and the leading rendered more effective. There was no conceivable reason why the supreme commander of any tactical operation should be, as at present, a nominal commander only. With him, on his shoulders, lay the responsible task of conceiving and drawing up the plan of operations. Why might he not control generally the conduct of these operations? Why might he not determine what modifications should take place in it during its execution? One of the most generally acknowledged weak points of modern warfare was the rapidity with which troops passed out of the control of their commander. There seemed to be an idea that tactical operations must necessarily be conducted on an entirely different principle from that which governed all other military operations, and must be a sort of Donnybrook Fair from commencement to finish. But, surely, there was a judicious mean between close centralisation and unbridled licence. Colonel Hale afterwards reviewed the operations of the German army in 1870-1, and pointed out how circumstances would have been changed if army corps had been in telegraphic communication.

After some preliminary account of the invention and progress of the telegraph for civil purposes Major BERESFORD said:—

The third of a century has just gone by since, in March, 1855, the first field telegraph in war was laid in the Crimea, and as to the British army belongs the honour, so let us trust that the British army will show the way in the future development of the speediest and safest of messengers. Those who have watched the gradual growth of war telegraphs in the British army must have observed the great progress made of late years, and the great and increasing reliance which is placed upon them. Looking away from our own army to the armies of other countries, we see a similar progress going on, and in all we see the desire to extend the telegraph to the utmost limits of active operations. This is very clearly pointed out in a most interesting article in the "Jahrbücher" of the German army and navy for February and March of the present year; the article is by Herr von Fischer Treuenfeld, who shows how by their latest organisations and by the increasing proportion of light cable now being adopted in all armies, a more extended use of the telegraph is clearly foreshadowed. General von Chauvin, the Director-General of Telegraphs in Germany, in his work on the army telegraphs, states that their tactical use during the war of 1870-71 was only prevented by the fact that there were no telegraph troops that had been trained for the purpose during peace. But it had been clearly recognised in Germany before the war that the telegraph could be used on the battle-field itself. In the French army there is not only outpost cable provided, but each cavalry regiment has six telegraphers, with suitable equipment, for establishing intercommunication in the cavalry divisions, and for destroying or repairing the lines of the country. Russia has also an organisation for cavalry telegraphers. The whole telegraph equipment of Spain is of light cable carried on pack animals, and is organised with a view of pushing the electric communication to the utmost limits. Italy, Austria, Belgium, Sweden, America, have all their outpost equipment.

But now we come to the fact, that in spite of all the preparations, there are only a few isolated instances of any tactical use having been made of the telegraph, and I am not aware of its having been thus used to any extent during the great peace manœuvres of Continental armies; for this there must be some cause which universally hinders the progress. Apart from a certain prejudice existing in many armies against a too extended use of telegraphs, the cause is not far to seek. To be efficient, a field telegraph must be reliable; and hitherto no organisation and no instruments or wire for outpost work have been introduced into active operations, at least in foreign armies, that give reliable results; commanding officers have not cared to deal with an uncertain subject. The feeling, so widespread in our army, that the telegraph could never be made reliable for tactical operations is, probably, an outcome of the unnecessarily faulty equipment with which the telegraph troop was provided some twelve years ago. At that time endeavours were made on many occasions in the neighbourhood of Aldershot to use the telegraph tactically, and though communication was often established by its means between the centre and flanks of one of two contending forces, yet it was discredited by frequent failures on other occasions. The cause of these failures was nothing to commanding officers; their verdict was "the telegraph has failed." Now all this time the telegraph troop had been trying to make bricks without straw, to establish communication through cables which age and long days of drill had rendered rotten as ropes of sand, and with instruments wholly unsuited for the purpose. Deaf ears were turned to the remonstrances of those who were in charge, and so the telegraph was discredited for tactical use. We are now in this position, that we have surmounted the two chief obstacles that confronted our advance, *i.e.*, the want of suitable instruments and suitable wires. The field telegraph instrument almost universally used on the Continent is the Morse recorder, in one form or another. The sounder is essentially the British and American instrument; any recording instrument—that is, an instrument in which the signals are received on a tape run out by clockwork—must be delicate, complicated, and unsuitable for rough usuage in the field, and could never be efficient for outpost telegraphy. The chief objections to a cable in the field are, that hitherto it has been heavy, expensive, and, when the wire inside becomes broken from any cause, the fault is difficult to find and repair. Now, Captain Cardew has invented an instrument, a combination of the telephone and sounder, which is simple in construction, and so sensitive to the electric current that it will work in all weathers, through common bare wire lying on the ground. On the other hand Messrs. Siemens Brothers have produced a cable so much lighter and so much stronger than former cables, that it will be almost unnecessary to have recourse to bare wire except as a matter of cheapness. During the campaign on the Nile a very considerable use was made of Captain Cardew's earlier forms of instrument which was worked through bare wire lying on the ground for many miles. Since then the use of such lines has been largely extended in Egypt. The two principal purposes which outpost telegraphs would be used for are—(1) Obtaining information. (2) Transmission of orders. And for these purposes they might be used in connection with—(*a*) Outposts; (*b*) Reconnaissances; (*c*) On the field of battle. With outposts, lines might be run as opportunity occurred from the reserves to the supports, and from the supports to the piquets. Short and still lighter lines might extend from piquets to special posts, or accompany reconnoitering patrols. With reconnaissance by cavalry or infantry, light lines might accompany as far as possible according to circumstances. On the field of battle lines might raidiate from a central station, say the advanced station of the trunk line, to the different points in rear of the position. A second radiating circuit might be run from centre to the artillery positions, not only for the purpose of controlling artillery fire, but also to serve as an alternative line in case of accident to the other wire.

I now come to the matter of organisation, and this at once opens up a fundamental question, *i.e.*, Would outpost telegraphs be best served and carry with them most success if worked by a special telegraph corps, or by a regimental organisation? The trunk lines of telegraph from base to advanced guard, and connecting army corps, divisions, and brigades, are essentially an engineering service, and both officers and men require a long technical training, not only to enable them to deal with the engineering points, but also for the management of what is often a most intricate matter of organisation. The instrument clerks, moreover, on the main lines must be the best that can be obtained, in order to cope with the immense mass of traffic. But on the proposed outpost lines, when the same methodical system would not be required, and messages in great numbers would not be passing, a much lower technical skill would suffice. In making this statement it must not be understood to mean that the higher the technical skill the efficiency of the service would not also be greater. For the more the duties of a telegraph clerk have become a second nature to him the less is he subject to excitement and flurry in emergencies. As regards the proposed organisation for regimental outpost telegraphers, each regiment of cavalry or infantry might have ten trained telegraphers (who would also be regimental visual signallers), an equipment of from one and a-half to two miles of light cable, and three or four sets of station material; the whole to be carried on pack animals, or in a light one-horse cart. The weight of cable such as lies before you being about 70lbs. per mile, two miles would be 140lb. Four instruments would weigh about 30lbs. The necessary batteries and other equipment, about 100lb.; taking 200lb. as a load for one animal, two pack animals would be required to carry everything, weight of forage, blankets, saddles included. A light one-horse cart would doubtless be much the more serviceable mode of transport. The French cavalry equipment is all carried in light one or two-horse carts. The Spaniards carry all the telegraph equipment on mules, with a maximum load of 320lb. They are quite satisfied that their experience proves that field cable is reliable under all circumstances.

I would sum up the points for discussion as follows, asking you to take it for granted that the physical difficulties to outpost telegraph lines are overcome. 1. Is it desirable to extend the telegraph to the utmost limits of an army in the field, if circumstances would admit of it? 2. Would an organisation for giving effect to this be better carried out regimentally or by the Telegraph Battalion? 3. If the principle of outpost telegraphs is admitted, is not the nature of the service distinct from that of the main lines connecting the various parts of an army, and if the outpost telegraphs are regimental, should they not be carried out by the regimental signallers, who should be trained accordingly, while the signallers for the main lines should be highly skilled telegraph clerks, and belong to the Telegraph Battalion?

After the discussion, Lord WOLSELEY, who presided, said that telegraphy had a great tactical future for England, and the nation that would first adopt a system of telegraphy in the field during action would have on its side a force which would give it many chances. He himself believed in novelties. What Napoleon had said was true, that you must change your tactics frequently. But the difficulties of doing so were not fully appreciated outside the charmed circle of official life. The necessity for guns could be shown, and advice might be given on all hands that

Digitized by Google

proper organisation would need corps of cyclists and other things; but he should like those who suggested these things to have to go before the Secretary of State for War with their views; then they would get the answers to why these things were not adopted. Why, even the state of our forts at home and abroad, owing to neglect, was most discreditable to the nation and to every one responsible. When the facts were laid before the authorities, it did not matter whether it was a question of guns, of repairs to forts, or the provision of new facilities of communication or anything else, the same process went on. First, there was a large expenditure of pens and ink on the part of some, and of patience on the part of others. One gentleman would write a minute upon any subject to a gentleman, his friend, in the next room, and after the repetition of this process the matter would at last get to the hands of the Secretary of State for War, who, advised by his financial friends, at once told the army advisers that there were no funds. If the army authorities asked for requisites for the army, they were told that they must "economise" in some way to get them. If machine-guns were asked for, then the reply came that the fighting men must be reduced, or, under the same conditions, carts and horses which were necessary for any army would be supplied. If the country went on longer in this way—knocking off cavalry and artillery whenever increased expenditure was required—the army would soon be reduced to two men and a boy. There had been an earnest endeavour made on the part of the army authorities, as all connected with the army knew, to organise a force which might, from necessity, have to be sent abroad—two army corps and one cavalry division. So far as the men were concerned, he was justified in saying that the men could be got ready to be put on board the ships before the ships could be got ready, and the nation could thus be defended from an enemy by striking that enemy elsewhere. But it was of no use talking of the necessity of providing novelties like telegraphs, when the army had not even stores or transports. Most important as it was to have such things as telegraphs, the army felt it was of no use asking for them when it was thus deficient in the first means of moving. He cordially agreed with all that had been said as to the importance of having telegraphs for the army; and he would ask the meeting to thank the lecturers and all who had taken part in the discussion.

COMPANIES' MEETINGS & REPORTS.

London Platino-Brazilian Telegraph Company (Limited).

The ninth ordinary general meeting of the shareholders in this Company was held at Winchester House, 50, Old Broad-street, on the 23rd inst., under the presidency of John Pender. Esq.

The SECRETARY (Mr. William Payton) read the notice convening the meeting and the minutes of the eighth ordinary meeting, which were approved by the present meeting and signed as correct by the Chairman. The report of the Directors was taken as read.

The CHAIRMAN: When I last had the pleasure of addressing you I referred at some length to the negotiations which were then going on between the Western and Brazilian Company and this Company. I am not in a position to-day to say that those negotiations have advanced in any way. The Brazilian Submarine Company have had a battle to fight with the Brazilian Government, and, so far as I can see at the present time, that question has also been placed in abeyance. There was an attempt to get an opposition company, and no doubt that opposition company would have materially interfered with the Brazilian Submarine Company and, consequently, with the Western and Brazilian Company. So far, therefore, as these negotiations are concerned, we may say that they are in abeyance at the present moment. I am pleased to say that our position in the meantime has very materially improved, and, as you can very well understand, an improved position gives us a better opportunity, when negotiations are resumed to maintain our interests. We are in a better position now than we have been at any time since these negotiations were opened. You will observe that the receipts from cable messages to the end of December, 1886, were £13,420, as compared with £8,614 in the previous year, showing an increase of 55 per cent. The land lines revenue account shows a very considerable increase, and after deducting all outgoings we have a net profit on that account of £7.559, as against £3,537 in 1885, or more than 100 per cent. increase. That, gentlemen, is a very marked increase indeed, and if this Company, when originally founded, had been established on such principles as we should found it on to-day, there would be a very satisfactory return upon both our cable and land lines. Unfortunately, however, this Cable Company, when it was formed, was saddled with very large amounts which never went either to construct cables or land lines. However, as you are aware, we rescued this affair practically from wreck and ruin, and I am pleased to say that I think we have now placed it upon a very fair and firm foundation. We are very much indebted to our manager in Uruguay, Mr. Lanza, and also to the staff under his command. Our last accounts from him were to the effect that he had travelled on horse-back with his line men over something like 900 miles. He reports our lines to be in a very efficient state, and that is to us not only assuring but also very gratifying. As you know, a submarine or land line system, to be useful in every sense, must be maintained in a thorough state of efficiency. Our cables are also in good working order. I am glad to state that Mr. Lanza from his position there seems to have an influence with the Government, and that we are getting fairly paid for the work we do for the Government, and that is considerable. At one time we were disposed to look on the large amount the Government owed us as not being a very good asset. We have realised that to a very large extent, and consequently we are financially in a sounder and much better position. Since the present Board have been in office they have been able to distribute in dividends about £64,000, and the average dividend for the last seven years has been close upon 2½ per cent. This year we are able to pay 3 per cent., and we hope with good fortune to have a continuance of a fair dividend. With these remarks I beg to move the following resolution—"That the report and accounts for the year ended 31st March, 1887, submitted to this meeting, be and they are hereby received and adopted, and that a dividend of 4s. per share be declared, payable this day (free of income-tax), making, with the interim dividend already paid, a distribution at the rate of 3 per cent. per annum."

Captain FRANCIS PAVY seconded the motion.

The CHAIRMAN: Before I put this motion to the meeting, if any gentleman has any question to ask I shall be happy to answer him.

A SHAREHOLDER: Can you tell us anything as to the prosperity of Uruguay? You would be better informed than we are.

The CHAIRMAN: Well, I have always said that there is no better barometer of trade or progress in any part of the world than that shown by the telegraphs; and, as I have mentioned to you, our increase has been very considerable.

Mr. W. GRIFFITH wished to be informed of the state of the dispute between the Company and the Western and Brazilian Company. With their dividend and their business increasing, perhaps a little more confidence would be inspired in the public if they were not in danger of getting into litigation with any other company, although, of course, the shareholders must support the Directors in upholding the rates. From the balance-sheet it appeared that the contract with Messrs. Lamas and Co. had not been fully carried out. It would be a good thing if that matter could be wiped out, and they could present the public with a clean balance-sheet. He saw that they had lost a little by their Uruguay Bonds, which during the present year had advanced considerably. If any of the bonds were still held by the Company, it seemed to him that the present was the time when they might be realised at a fair profit.

The CHAIRMAN: My first reply is to Mr. Griffith's question as to the amount in dispute between this Company and the Western and Brazilian Company. As to that I do not think it would be desirable when negotiations are pending that we should go into the details of the figures. I think as an old lawyer Mr. Griffith will agree with this. As to the contract with Messrs. Lamas, that is a question which we consider practically settled. Any security that exists we hold, and we do not think the company is ever likely to be liable on that account. As to the Uruguay Bonds, we have been singularly fortunate. It is not our business to hold securities of that kind, but to convert them. We had to take these bonds at par, and as far as that fact is concerned, we realised them at a discount. Our sales have always been on the right side.

A SHAREHOLDER: Were not Messrs. Lamas the contractors who laid the cables?

The CHAIRMAN: No, the land lines. He then put the motion, which was carried unanimously. Continuing, he said, I have now to move "That Mr. John Hollocombe be and is hereby re-elected a Director of this Company." I may mention that Mr. Hollocombe has just returned from a visit to the territory over which our lines are connected, and I need not tell you that the information which Mr. Hollocombe has brought to us is in every way valuable. His advice and assistance as a Director are peculiarly valuable from his long residence in those parts and his recent visit there.

Captain PAVY seconded the motion, which was carried unanimously.

Mr. WM. FORD then proposed the third resolution, as follows:—"That Messrs. Deloitte, Dever, Griffiths and Co. be and they are hereby re-elected auditors of the Company at a remuneration of £25 for the year."

Mr. GRIFFITH seconded the motion, and it was carried unanimously.

Mr. WATKINSON proposed a vote of thanks to the Chairman and Directors. He thought they might all congratulate themselves on the improving position and prosperity of the Company. With such able administrators the shareholders' interests would be well looked after.

A SHAREHOLDER seconded the motion, and it was carried unanimously.

The CHAIRMAN: It is a great pleasure to my colleagues and myself to have satisfactory opinions expressed of our management. It is not only our desire to make this Company successful and prosperous, but it is also the desire of all of us who are connected with telegraphy on a broader scale that every link in our great chain should be successful. We thank you very much for your confidence.

The proceedings then terminated.

The Consolidated Telephone Construction and Maintenance Company (Limited).

Report of the Directors to be presented to the sixth annual general meeting of the Company, to be held at the Cannon-street Hotel on Thursday, June 2, at 12 o'clock:—

The accounts for the year ending the 31st March last show a net profit of £8,957. 4s. 4d., which, with the amount carried forward from last year, leaves a balance of £10,127. 8s. 6d. for disposal. The Directors propose to deal with this amount as follows, viz.:—to pay a further dividend of £2. 10s. per cent, making, with the interim dividend paid in November last, 5 per cent. for the year, writing off the sum of £558 for depreciation of plant and machinery, and furniture, thus leaving a balance of £1,695. 18s. 5d. to carry forward. The amalgamation of our subsidiary company, the River Plate Telephone and Electric Light Company, with the United Telephone Company of the River Plate has become an accomplished fact. As a consequence of this amalgamation, the shares held by this Company in the late River Plate Telephone Company have ceased to exist. The Directors have received £19,877 in

Digitized by Google

cash, in payment of the debt owing to the Company by the late River Plate Telephone Company, also £1,250 as compromise for a contract which that company had failed to fulfil for the supply of telephones. The cumulative 9 per cent. dividend amounting to £1,838 17s. 10d. up to 31st January, 1886, has also been paid to the Company, and an amount standing in the books at the sum of £9,256 has now been converted into £8,985, in shares in the United River Plate Telephone Company (Limited), at par, and £11 564 in cash has been received, which amount is now available for distribution. A further considerable amount has to be received in connection with the amalgamation. Out of the amount of capital returned to the Company under the above-mentioned arrangements, the Directors propose to dispose of £11,242. 10s. by returning 1s. per share from the issued capital of the Company, thereby reducing the nominal value to 14s. They also propose out of the amounts received to write off from the good-will and patents accounts the sums shown in the statement accompanying the report. The Directors have done all in their power to extend the sale of the Company's manufactures abroad, and with this in view they exhibited at the Exhibition of Telephones, held in Brussels in the early part of this year. It was admitted on all hands that the articles manufactured by this Company took the first place, and the Board trust that good results will follow. Every effort has been made to keep down the working expenses, and but for the exceptional causes of the Belgian law suit, and the action which Colonel Gouraud has brought against the Company, the present year's charges would have been less by a considerable sum than last year. This action against the Company has been postponed from time to time, and at his further request the trial has now been postponed till after the 1st June next. Colonel Gouraud has also thought fit to commence an action against the Directors for the course they have pursued, with your sanction, in co-operating with the Edison Gower-Bell Telephone Company in the action to prosecute infringers of their patents in Belgium. Thus far, in Belgium all has gone on favourably to this Company, though every obstacle has been thrown in our way. It is impossible to foretell what the result will be should the suit be decided in our joint favour. It may, however, be stated that the damages claimed involve a very considerable amount. Negotiations are also proceeding by which the business of the Edison Gower-Bell Telephone Company in Portugal will be considerably improved. The Directors have now purchased the entire machinery of the American Telephone Company, which was in use in the Company's factory, for the sum of £2,300, thus placing the establishment in a most perfect and independent position with regard to their manufacturing capability. The business of the subsidiary companies, in which this Company is so largely interested, continues to make satisfactory progress. The Telephone Company of Austria at the end of March, 1886, had 1,373 subscribers, representing a gross annual rental of £9 258. At the end of March, 1887, there were 1,791 subscribers, with a gross income of £11,682, showing an increase of 418 subscribers and £2,424 on the annual rental. The Edison Gower-Bell Telephone Company at the end of March, 1886, had in its two exchanges—Lisbon and Oporto—1,105 subscribers, paying a gross annual rental of £6,800. At the end of March, 1887, there were 1,370 subscribers, paying a gross annual rental of £8,778. This shows an increase of 265 subscribers, and £1,978 rental during the year. The increases in the exchanges as compared with 1886 may therefore thus be stated :—

Telephone Company of Austria	418 subscribers	£2,424 rental
Edison Gower-Bell Telephone Company ...	265 ,,	1,973 ,,
Total increase for the year.....	683	£4,402

It is with sincere regret that the Board have to announce the death of one of their colleagues, Mr. John Taylor, whose services proved of great value to the Company. Major FitzGerald and Mr. R. E. Bateman having taken their seats at the Board of the United River Plate Telephone Company, the retirement of these gentlemen from the Board of this Company became necessary as part of the arrangement of the amalgamation. In accordance with the Articles of Association the following Directors retire by rotation, and, being eligible, offer themselves for re-election, viz., C. L. W. Fitz-Gerald, Esq., and Richard Van-Zeller, Esq. The auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and A. E. Green, Esq., also retire, and offer themselves for re election.

An extraordinary general meeting of the Company will be held immediately following the ordinary general meeting, when the following resolution will be proposed as a special resolution, subject to subsequent confirmation :—

"That the capital of the Company be reduced from £243,787. 10s. divided into 224,850 shares of 15s. each and 75 150 shares of £1 each, to £232,545 divided into 224,850 shares of 14s. each and 75,150 shares of £1 each, and that such reduction be effected by returning to the holders of the 224,850 shares that have been issued, paid up capital to the extent of 1s. per share, and by reducing the nominal amount of such 224,850 shares to 14s. each."

Should the resolution be passed by the requisite majority it will be submitted for confirmation as a special resolution to another extraordinary general meeting, which will be subsequently convened.

CRICKET.

EASTERN TELEGRAPH COMPANY v. R. MACKAY AND CO.

The first of a series of matches arranged by the Eastern Telegraph Company to be played this season took place on the grounds of the West London Cricket Club, Wormwood Scrubbs, last Saturday, the 21st inst., their opponents being *employés* in the firm of Messrs. R. Mackay and Co., accountants. The Telegraph Company, winning the toss, elected to go in first, sending in Messrs. A. W. Prosser and J. G. McMillan, who played an excellent game, both hitting hard, and running up the creditable score of 59 ere they were separated. Mr. W. McDonald joined Mr. McMillan; but the "two Macs" were not so successful, McDonald getting clean bowled after augmenting the score by 3. On Mr. G. Jack going in, however, the score again rapidly rose, this gentleman succeeding, by excellent cricket, in putting on 56 runs. None of the remainder, with the exception of Mr. Hensman, made anything of a stand, the innings closing for 155. After a short interval Messrs. Mackay's representatives handled the willow, opening badly by Mr. McMillan disposing of their first man, Mr. R. Finlayson, for 3 runs. The excellent bowling of Mr. MacMillan, who secured 7 of the wickets, was apparently too much for the team, the only member making anything of a stand being Mr. R. H. Hoare, who by careful cricket run up 13. The innings closed for 26, thus leaving the Telegraph Company victorious by 129 runs. We annex the scores :—

EASTERN TELEGRAPH COMPANY.—J. G. McMillan, c. Richardson, b. Head, 37 ; A. W. Prosser, c. Spillwell, b. Head, 25 ; W. McDonald, b. Head, 3 ; G. C. Jack, b. Finlayson, 56 ; C. Hensman, b. Finlayson, 21 ; G. Munro, c. Edmunds, b. Head, 0 ; A. Donaldson, lbw. b. Head, 1 ; E. D. Payne, c. Finlayson, b. McLennan, 1; T. Richardson, b. Finlayson. 1; C. Saunders, not out, 1 ; W. Grigor, b. Finlayson, 3 ; extras 6—total 155.

MESSRS. R. MACKAY AND CO.—R. Finlayson, b. McMillan, 3 ; R. H. Hoare, c. Grigor, b. McDonald, 13 ; W. H. Head, run out, 2 ; R. R. Edmunds, b. McMillan, 0 ; W. J. Stilwell, c. Richardson, b. McMillan, 2 ; C. S. Stuart, b. McMillan, 1 ; R. Murray, b. McMillan, 0 ; G. H. McLennan, b. McMillan, 1 ; H. Limebeer, b. McMillan, 0; C. B. Syer, not out, 0 ; A. H. Cullen did not bat ; extras 4—total 26.

CITY NOTES.

THOMSON-HOUSTON INTERNATIONAL ELECTRIC COMPANY.—The general European office of this company will be transferred to the new Singer building, Admiralitätstrasse and Michaelisbrücke, Hamburg, Germany, on June 1st next.

J. G. STATTER AND CO. (LIMITED).—The business of Messrs. J. G. Statter and Co., of the Alliance Engineering Works, West Drayton, and of Middleton-road, Dalston, has been transformed into a limited liability company, with a capital of £20,000 in £10 shares. The vendors receive £6,400 entirely in shares of the new company.

NOTES.

MANOSQUE (BASSES ALPS).—The village of Manosque will shortly be supplied with a central station for electric lighting.

RAILWAY STATION LIGHTING AT BRUSSELS.—The Belgian authorities have had their attention drawn to the imperfect character of the lighting of the Brussels railway stations, and steps will probably be taken to light the three principal stations by electricity.

THE HOLYHEAD CABLE.—The telegraph cable between Howth and Holyhead, containing seven conductors, of which four are defective, is being taken up for repairs, and will be relaid by a more favourable route, the bottom on the Welsh coast being reported unsuitable.

PERSONAL.—Mr. A. A. Campbell Swinton, until recently electrical engineer to Messrs. Sir W. G. Armstrong, Mitchell and Co., Newcastle-on-Tyne, has removed to London in order to undertake the management of the Equitable Telephone Association (Limited), 75, Queen Victoria-street, E.C.

TELEGRAPH STORES REQUIRED.—Tenders are asked by the North-Eastern Railway Company for the supply of telegraph apparatus, wire, and line stores. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York Station, and must be returned by noon on the 7th inst.

BOURNEMOUTH.—Mr. J. J. Norton is erecting at Bournemouth a building which is intended for a free library and school of art. In order that the building may be completed within the Jubilee year the work is being pushed on day and night. Messrs. Mortimer and Shepherd are supplying electric light for the night work.

ELECTRIC LIGHTING AT THE INNER TEMPLE.—Messrs. Drake and Gorham have just completed a considerable extension of the storage plant at the above installation. The new battery is capable of supplying 75 lights for 9 hours, and, we are informed, contains all the latest modifications and improvements introduced by Messrs. Drake and Gorham.

THE KHOTINSKY INCANDESCENT LAMP.—We understand that the German Edison Company has commenced an action for the infringement of its patents against the makers of the Khotinsky incandescent lamp. The head-quarters of the latter company are at Rotterdam, but a factory has recently been established at Cologne, and the lamp has met with some success in Germany.

CENTRAL STATION LIGHTING AT BERLIN.—The Stœtische Elektricitœtswerke Company is about to undertake two new central station installations at Berlin. One will supply light to the district of Dorotheenstadt, and the other will be placed in the old quarter of the city. Each station will be capable of supplying 6,000 16 candle-power lamps from the first start, but an extension to a total of over 10,000 lamps will be provided for.

THE SCHOOL OF ELECTRICAL ENGINEERING, HANOVER-SQUARE.—In addition to the results quoted in our issue of May 20th, the following students, who had previously gained the school's certificate in lighting and power transmission, obtained it also in telegraphy and telephony in a recent examination by Mr. H. R. Kempe, with the following percentages :—Sanders, 100 per cent.; Mott, 96 per cent.; Levin, 78 per cent.; Ryves, 70 per cent.

REPRODUCING.—We have very great sympathy for the troubles of literary men, but we think that a mild remonstrance, if nothing more, is required when original articles are taken from *The Electrician* and credited to our London contemporary, as has been done with the article "On Regulating Series-Wound Transformers" which appears in the American *Electrical Review* of May 21. There can be no difficulty in crediting original articles to the proper source, and we trust that in future our American contemporary will be a little more careful in this matter.

HOTEL VICTORIA, NORTHUMBERLAND AVENUE. — The electric lighting of the Victoria Hotel has been carried out by Messrs. Thompson, Ritchie and Co., of Winchester House, E.C. The plant comprises two pairs of vertical engines by Messrs. Browett Lindley, each engine driving an Elwell-Parker dynamo capable of doing the whole of the lighting required, so that a complete duplication is secured. There is also a set of E.P.S. accumulators for the lighting after midnight. The number of lamps exceeds 1,000. The fittings have been supplied by the Walsall Electrical Company.

SHIP LIGHTING.—The ss. "Earnholm," belonging to the Aberdeen, Leith, and Moray Firth Steam Shipping Company, has been fitted with electric light by Messrs. Andrews and Co., of Glasgow. The dynamo is driven at 650 revolutions by a Tangye high-speed engine, running at 150 revolutions. The ss. "Tantallon Castle" has been fitted with an installation of thirty-five 20 candle-power Swan lamps, supplied with current by a "Kennedy new type ironclad dynamo," run at 650 revolutions. The work has been carried out under the superintendence of Mr. Jas. Campbell, of Mr. Kennedy's firm.

THE UPWARD BATTERY.—Messrs. Woodhouse and Rawson have just completed an installation of this syetem for lighting the private residence of E. Harlock, Esq., at Ely, Cambridgeshire. The plant consists of four Upward cells, with eight columns for holding the chlorine gas, and a set of E.P.S. accumulators of the 11L type. The battery is fixed in the brewery adjoining the house near the mash tun, and immediately below the fermenting tuns—a convenient position, which we are informed could not have been made available but for the entire freedom from smell or noxious fumes from the battery.

INFLUENCE OF ELECTRICITY ON DELICATE WEIGHING.—M. Hennig de Wurtzbourg having noticed some incomprehensible differences in the weights of equivalent quantities, undertook investigations, which showed that balances of precision are often influenced by the electric state of the glass case which surrounds them. This electricity influences the "riders" which slide on the beam of the balance. The error resulting from this influence may amount, it is said, to 600 milligrammes where the case is strongly charged, and two hours afterwards there may still be an error of 10 milligrammes.

A LEAD-IRON ACCUMULATOR.—Under the name of the Kalischer accumulator, a storage cell, with plates of lead and iron, or carbon, has been brought out. The exciting liquid consists of a solution of lead nitrate, the lead plate being amalgamated, and kept in contact with mercury. During the process of charging, the iron plate receives a coating of lead peroxide, which protects it from the solution, the peroxide being, of course, reduced during the discharge. We are not aware what are the peculiar advantages claimed for this cell, although, doubtless, they must be very weighty to compensate for disadvantages which are obvious on the most casual glance.

THE TRANSMISSION OF POWER AT THE MANCHESTER EXHIBITION.—We would call the attention of our readers to the description, which will be found in another column, of the admirable results shown by Messrs. Mather and Platt in the driving of complicated machinery by electric power at the Manchester Exhibition. The complete demonstration of the fact (already familiar to electricians) that electric transmission of power in factories may not unfrequently effect an actual saving in working expense is very noteworthy from the point

Digitized by Google

of view of the outside public, and will, we may well hope, lead at an early date to an increased appreciation of the advantages of electrical working, and a correspondingly large increase in its application.

ABANDONMENT OF THE JULIEN SYSTEM AT HAMBURG.—We regret to learn from *La Lumière Electrique* that the annual report of the Tramway Company of Hamburg recommends that the present method of electric traction by means of Julien storage cells shall be given up at the end of the present year. The system is said not to have given such satisfaction as had been anticipated, but no specific fault seems to have been alleged in the report. On the other hand, the Berlin Tramway Company, after examining the working of the system at Cologne, has declared in favour of its adoption. In America also the Julien cells seem to meet with success, so that we should not be surprised to learn that the failure at Hamburg has been the result of bad management on the part of the working staff.

THE NEED OF A PORTABLE ELECTRIC LAMP.—The fatal colliery explosions of last week in England and Scotland have led Mr. Ellis Lever, of Manchester and Colwyn Bay, to renew his offer of £500 for the production of a perfect portable electric miner's lamp within the Jubilee year. More than 50,000 miners have lost their lives by accidents in coal mines during the half century of the Queen's reign. On the same subject a correspondent writes us from Belgium:—"A lamp, giving the light of from 50 to 100 candles for a period of five hours, and not weighing more than 10 or 12lb., with self-contained battery, is in request by the engineers of the Prince Henry Railway Company, Luxemburg, for permitting the inspection of the roof of mine workings. The lamp should be provided with a strong lens and reflector, so that the rays may pierce the dense smoke caused by blasting."

THE DRY PILE.—Prof. Palmieri has recently presented a note to the Academy of Sciences at Naples embodying the results of a study of the so-called dry pile of Zamboni, extending over many years. He arrives at the conclusion that, provided only that care be taken to shut the battery in an hermetically sealed case, the difference of potential will remain absolutely constant for an indefinite period. It is not even necessary to employ any artificial means for drying the air. If the atmosphere remain unchanged this is quite sufficient to ensure the constancy of the pile. The presence of a slight trace of moisture is, in fact, favourable to the development of a higher E.M.F., without impairing its constancy. Prof. Palmieri considers that for maintaining an invariable charge in an electrometer the dry pile, under the above conditions, is far superior to the usual Leyden jar and sulphuric acid arrangement.

THE WRECK OF THE "VOLTA."—Her Majesty's Government have awarded the following rewards to the crew of the boat of the Hellenic steamship "Karteria," which, in circumstances of much risk and difficulty, took off from the rigging of the "Volta" thirteen of the crew of that vessel, on the occasion of her wreck off the island of Mykonos, on April 18th, 1887:—A gold shipwreck medal to S. Vetmis, coxswain, and a silver shipwreck medal each to G. Sarpas, J. Samiotis, C. Micaros, M. Bournias, S. Damulakis, and M. H. Nikiti. Her Majesty's Government have also awarded a binocular glass to Captain J. V. Velissarios, master of the "Karteria," in acknowledgment of his humanity and kindness to the shipwrecked crew on the occasion. We understand that the Eastern Telegraph Company have also made substantial acknowledgements of the bravery displayed by the Greek sailors, and the extreme kindliness of the islanders to the shipwrecked crew.

LIVERPOOL TELEGRAPHIC GRIEVANCES.—The Postmaster-General has sent Sir William Forwood the following letter with reference to the complaints of delay in the transmission of messages between that city and the Continent:—

"Dear Sir William: I write to acknowledge the receipt of your letter conveying to me the resolutions passed at your meeting, together with a report of the proceedings. I can assure you that I fully realise the importance of the question, and anxiously desire to meet, as far as is practicable, the complaints which have been brought before me by Messrs. Hemelyrk and others. At the same time you must bear in mind that my most experienced officers do not recognise the substantiality of some of the grievances to which you call attention. I have this afternoon seen Lord Claud Hamilton on the subject, and have communicated to him my readiness to see you and any other gentlemen interested in the matter with him after the Whitsuntide recess, and he will, I have no doubt, arrange with you a convenient time for the interview.—Yours very faithfully, HENRY CECIL RAIKES."

SODIUM-BICHROMATE VERSUS POTASSIUM-BICHROMATE.—In the American *Journal of Science* Mr. S. L. Harding gives the result of some experiments undertaken to test the comparative merits of the bichromate salts of sodium and potassium. In the first place, for a given weight of solution the sodium salt starts with a very considerable advantage in respect of solubility. At 15° C., water dissolves 12·5 parts of potassium-bichromate and 83·16 parts of anhydrous sodium-bichromate. From this it results that the amount of available oxygen in a saturated solution of the sodium salt is 0·0852 per cent., as compared with 0·018 per cent. for the potassium salt. As a consequence, when two cells are set up containing equivalent weights of material, it was found that a sodium salt cell ran on an average fully twenty hours, or more than one-third longer than the potassium salt cells. The E.M.F. of the two cells is slightly in favour of the sodium, the figures obtained being 1·893 volt, and 1·892 volt. The internal resistance of the sodium salt cell amounted to $0{\cdot}4967\omega$, while that of the potassium salt cell amounted to $0{\cdot}468\ \omega$.

THE BRUSH ARC LAMP AT MANCHESTER.—Mr. W. B. Sayers writes us from Manchester as follows:—"I see among the notes in your issue of the 20th ult. an explanation of the reason why the lamps in the gardens at the Newcastle Exhibition were unsteady, *i.e.*, that they could not be regulated prior to the opening night in consequence of the contractors being late with their work. I should like to draw the attention of your readers to the fact that the whole of the 500 odd Brush lamps now fixed and burning nightly in the Manchester Exhibition have been put together and hung just as they were received from the Anglo-American Brush Electric Light Corporation's works, Lambeth, and that practically none (actually less than 3 per cent.) have required any alteration of adjustment. As a large number of your readers will know that I can claim no credit for this myself, I feel at liberty to call attention to what all who have had any experience with arc lamps will admit to be a very creditable performance on the part of the management and staff of the Anglo-American Brush Electric Light Corporation (Limited)."

CENTRAL STATION LIGHTING IN PARIS.—The company which has undertaken to light the Quartier du Panthéon is making rapid progress in the construction of their central station in the Rue de la Montague-Sainte-Geneviève. The building itself is almost completed. It has been decided to employ dynamos made by Brown, of Oerlikon, and this firm will also supply the whole of the electric material and apparatus. Berthoud-Borel lead-covered cables will be employed, and

Digitized by Google

it is intended to lay them under the pavements. The authorisation for this work was obtained from the municipality more than two years ago by M. Marchand, who has disposed of his rights to the new company. This transaction recently gave rise to some discussion at a meeting of the Paris Council, and the principle involved in the sale and barter of rights accorded in the public interest was very properly condemned. No definite action has, however, been taken, and the position of the company in relation to this matter remains for the present somewhat uncertain, although there can be no doubt that the necessary sanction will ultimately be accorded.

A False Alarm.—Much excitement was caused in Vienna on Sunday evening by a rumour that a fire had broken out at the old Burg Theatre, where a performance was taking place. The actual facts were happily not of a serious character. At the new Burg Theatre (a building now in course of construction) a length of about 25 yards of insulated cable had caught fire and burnt itself out. Fortunately the wire was laid along an iron girder, and no further damage resulted. The cable was being used for the charging of accumulators, which are employed to light the men at work in the space underneath the stage. Although so little harm was done, the fact that the fire occurred in a theatre, and was undeniably due to the overheating of a conductor by the current, is doubly unfortunate at the present time. It will be interesting to learn the exact cause of the fire—whether it resulted from the employment of a too small conductor, or from a short circuit, or a reversal of the dynamo current. In either case the lesson should not be lost that, even under the most apparently favourable circumstances, every precaution should still be taken to guard against the possibility of these damaging "accidents."

The American Institute of Electrical Engineers.—We are very pleased to learn that a movement has been set on foot among the electrical community in the United States, which has for its object "to place the American Institute of Electrical Engineers on a firm and enduring basis," and to obtain for the institute a position in the scientific world such as that enjoyed by similar bodies on this side of the water. A further object of the movement is to obtain funds to build a house for the institute. These objects will undoubtedly have the warmest sympathy of the scientific and engineering professions in our own country. From a letter which we have received from two members of the council (Mr. Geo. M. Phelps, jun., editor of the *The Electrician and Electrical Engineer* of New York, and Mr. T. C. Martin, of *The Electrical World*) we learn further that although the movement has only recently taken shape after three years' talk the sum of $4,000 has already been contributed, and—though this is not specifically stated—we have no doubt that any contributions which our readers might be disposed to offer as a token of goodwill would be highly appreciated, irrespective of the actual amount.

The Electric Lighting of Dundalk.—The following paragraph from the *Dundalk Democrat and People's Journal* exhibits the effect produced upon the native—and, as it modestly describes itself, the "untutored"—mind, by the first display of the electric light in the town of Dundalk:—"Last night (May 27th) the town was fully lighted for the first time by the electric agency. The number of lamps agreed upon in the contract were illuminated. The light was clear, brilliant, and steady, and, to our unprofessional eye, the trial seemed a success. 'Tis true that a few of the lights failed to give satisfaction, but this seemed to be the fault of the lamps rather than the current, and therefore should be easily remedied. If Mr. M'Carthy succeeds in his undertaking the result will be a complete revolutionising of the public lighting of towns, and to our untutored mind he is on the high road to success if he has not already arrived there." Mr. M'Carthy, writing at a later date, informs us that since the first night's trial no further difficulty has been experienced in the adjustment of the lamps, and the installation is now working with perfect steadiness. The Town Commissioners have decided to contract for several additional arcs, so as to dispense with the remaining oil lamps in the streets of the town.

Injurious Effect of the Electric Light upon Plants.—According to the Berlin *Centralblatt der Bauverwaltung*, some disagreeable and unexpected results have followed the electric lighting of the Winter Palace at St. Petersburg, which was described in a recent note, the intense brilliancy of the light having been found to cause dire destruction among the ornamental plants used for the decoration of the banqueting halls. It appears that the complete illumination of the rooms for a single night is enough to cause the leaves to turn yellow and dry up, and ultimately to fall off. The damage to the celebrated collection of palms at the Palace is especially serious. It is supposed that the injury is principally due to the sudden change from the sunless days of the northern winter, and from the subdued light of the plant houses to the blinding light of the banqueting halls. It has been shown beyond a doubt that the rapidity of the injurious action, and its amount, are directly proportional to the intensity of the illumination, and plants standing in niches or other places partially shielded from the light are found to remain uninjured. There is no doubt that the injurious effects of the light are greatly intensified by the dry, artificially heated atmosphere of the rooms, and that they would be minimised, if not entirely obviated, if the plants could be surrounded by a steamy atmosphere, such as that in which they are grown.

Liverpool Naturalists and Electric Light Experiments.—The Liverpool Marine Biological Society chartered last week the ss. "Hyæna," belonging to the Liverpool Salvage Association, and sailed for the Menai Straits upon an expedition of discovery and research. The "Hyæna" is supplied with dynamo machinery, and carries a powerful search light at the masthead, as well as some submarine incandescent lamps supplied by Messrs. Siemens. The naturalists found much amusement during the evening in sweeping the Welsh coast with the powerful beam of the search light. The submarine lamp was lowered to a depth of 18ft., and although the lamp itself was lost to sight at less than half that depth, yet the surface of the water was lit up over a considerable area. Unfortunately the special object which the society had in view, namely, a study of the effect of the light upon the denizens of the deep was not realised. This was explained by the fact that the strong tides which run through the Menai Straits sweep the fishes along with them, so that however greatly their curiosity might have been aroused by the unfamiliar glare, they had no opportunity of gratifying it. This was, doubtless, as disappointing to the naturalists as to the fishes, but we cannot see that the latter were to blame. The naturalists ought certainly to have considered the effect of the tidal currents in drawing up the programme of their cruise. We shall hope to hear of better results on their next expedition.

Earthquakes and Electricity.—An Experimental Demonstration.—The following facts have been made the subject of a very careful investigation by the French military authorities, and there appears to be no doubt as to their absolute correctness:—On the 28th February, during the continuation of the disastrous earthquakes in the Riviera, a soldier in the fort of Tête de Chier at Nice, was engaged in

Digitized by Google

working a telegraph instrument communicating with another part of the town. At this moment the third earthquake of that morning took place; this was the least violent of the three great shocks. The soldier was thrown from his seat and received a severe *electric* shock through both arms and across the chest. It was some minutes before he recovered the power to move, and he remained in hospital for the rest of the day. As already mentioned the affair has received a most careful investigation, and the French authorities consider the fact to be thoroughly well established. The important question now arises, whether the electric phenomenon is a cause or an effect? In the light of the recent experiments of Prof. Milne in Japan (which will be found fully described on page 409 of our last volume) it will be seen that an earth current may always be looked for as the result of an earthquake, though when we consider the enormous amount of electric energy which must have been in play in order to knock down a man through what was practically a shunt-circuit of comparatively enormous resistance, it is impossible to deny that the electric force may as well have been the cause as the result of the disturbance.

THE ELECTRIC CONTROL OF COMPRESSED AIR BRAKES.—The method of applying a brake to the wheels of railway cars by means of compressed air could easily be arranged to give far more power than it is at present safe to employ if it were possible to ensure an absolutely simultaneous application to every wheel in the train. The methods hitherto adopted do not admit of this. If the brake is applied from the engine, a perceptible interval elapses before the last vehicle on a long train is reached. Hence, with heavy trains, the rapidity of the application of brake-power is limited by the factor of safety necessary to withstand the inertia of the hinder vehicles. The application of electricity to effect the simultaneous release of all the brake-blocks is an obvious resource, and it is perhaps surprising that more has not already been done in this direction. Some experiments of this kind were, however, recently carried out on the Illinois Central Railroad, and are reported to have yielded satisfactory results. Each brake block was supplied with an electro magnet within the air tubes, and so arranged that the application of the current opens the air valves by which the brake is applied. The wires are carried through the tubes, being connected with the metallic coupling pieces at either end, so that no special joint is necessary. An automatic device was also employed to ensure that when off duty the brake blocks shall stand always at the same distance from the wheels. A dynamo upon the engine supplied the necessary current. Some force is evidently required to open the valves against the pressure of the air.

THE WISH IS FATHER TO THE THOUGHT.—The following entertaining paragraph appeared in a recent number of our esteemed contemporary, the *Journal of Gas Lighting*, and clearly betokens a somewhat uneasy, not to say unkindly, feeling in the editorial mind. After giving some account of an installation recently erected by the Gülcher Company in a private house near Petersfield, and to which reference was made in our last issue, the writer proceeds:—"Only thirty-eight lamps are fixed in the house, so that the whole thing is on a small scale. It will be interesting to learn whether, after the novelty has worn off, the purchaser remains satisfied with his bargain. It is very pretty to have a nice house in the country fitted with incandescent lamps, and everything goes on very comfortably for a time. After the contractors' foreman has taken his departure, however, and when the plant has been definitely committed to the care of the "handy man," a change is apt to come over the aspect and performance of the machinery; and in the end it sometimes happens that the electric lighting engine terminates its existence in sawing wood." After all, this sort of thing strikes us as rather superfluous, for, as our contemporary truly remarks, the installation is quite on a small scale, so that the competition of gas lighting in this case (necessitating a private gas works) is entirely out of the question. It can therefore only be "pure cussedness" which gives rise to the ill-concealed aspiration that the electric light engine "may terminate its existence in sawing wood." For ourselves we have never doubted that electricity has a great future in the lighting of country houses.

THE SPEZIA ELECTRIC LIGHTHOUSE.—The *Standard* of the 2nd inst. contains the following letter, over the initials "C. P. S.:"—"Sir: In the course of an interesting discussion at the Institution of Civil Engineers, in December last, on the Electric Lighthouse of Tino (an islet at the mouth of Spezia Bay, opposite the beautiful promontory of Porto Venere), it was stated, as an instance of the extraordinary visibility of that light at long distances, that during the official trials in April last year the rays of its flashes (a group of three flashes every half-minute) illuminated the clock on the Tower of Volterra, no less than 75 miles distant and at an altitude of over 2,000ft. above sea level, casting a distinct shadow on the disc. The Tino light, of five to six million candle-power, is one of the most powerful in the world, and was put up early last year under the direction of Cav. L. Luiggi and the late Comm. Parodi, of Geneva, on behalf of the Italian Government, the optical apparatus and machinery having been supplied by Messrs. Chance Brothers and Co., of Birmingham, according to the design of Dr. John Hopkinson, M.I.C.E., F.R.S. I have lately had frequent occasion to observe the wonderful illuminating and penetrating power of that light from various points of the Tyrrhenean littoral, and in all weathers. Thus, from a point three thousand feet above sea level, in the Carrara Mountain range, from which, on a clear night, even the oil lights of Viareggio, Leghorn, and of the islands of Capraja and Gorgona are visible, the flashes of the Tino light shooting across the sea may be seen illuminating the whole coast of the marble district and the lower slopes of the mountains with almost magic effect. Seen from the pier of Viareggio, thirty miles distant, the brilliancy of the light is positively dazzling, and the shadow it casts of the Viareggio Lighthouse, or of persons walking on the pier, is distinctly observable. Nay, even in the intervals between the triple flashes, the light is clearly visible to the naked eye in the shape of a red spot just about the size and brilliancy of the old Tino oil luminary. Again, though dimmed by heavy rain and thick fog, as it has been during the last few nights, the triple flash is always clear and unmistakable, and then produces, through the quasi-opaque atmosphere, and at a distance of thirty miles, the effect of the blurred disc of the moon on a small scale. This remarkable penetration power of the Tino light is conclusive proof, not only of how admirably it is designed and suited to its essential purpose as a guiding light under the peculiar atmospheric conditions of the Mediterranean, but also how hazardous it would be to dip—viz., to divert such a light, as has been suggested by some—from the horizon to the nearer sea in foggy weather, forsooth, according to the *bene placito* of the man in charge, on the presumption that in such weather the luminous rays could not reach the horizon, and would therefore be wasted. This presumption is wholly fallacious in the Mediterranean; for in the Bay of Spezia, owing to its proximity to the Appennines, the rainfall is much greater than in other parts of the Tyrrhenean Sea, and banks of land fog can often be seen hanging over the bay and Tino when the horizon as far as Leghorn, Gorgona, and even Corsica is perfectly clear."

INCANDESCENT LAMP MANUFACTURE.—XVI.

BY J. SWINBURNE.

Exhausting Continued.

A very simple form of pump is the drop-over pump. It is the same in principle as that shown in Fig. 11, except that there is no contraction above E, and the tube is made large from U to E. The flow of mercury is regulated by the tap, and the mercury falls over drop by drop. This is the simplest form to make, and is suitable for amateurs. A development of it is also used by Messrs. Mark Bailey and Co.

If the Sprengel pump is wet, or even damp, it will not work properly; it is therefore necessary to dry the air from the lamp before it reaches the pump. A tube of phosphoric anhydride is therefore inserted. Other drying materials have been tried, but without success. Fig. 13 is a diagram of Mr. Gimingham's form of Sprengel pump, used by the Edison-Swan Company for a long time. It is said to be replaced now by Mr. Stearn's short shaft pumps, but it may

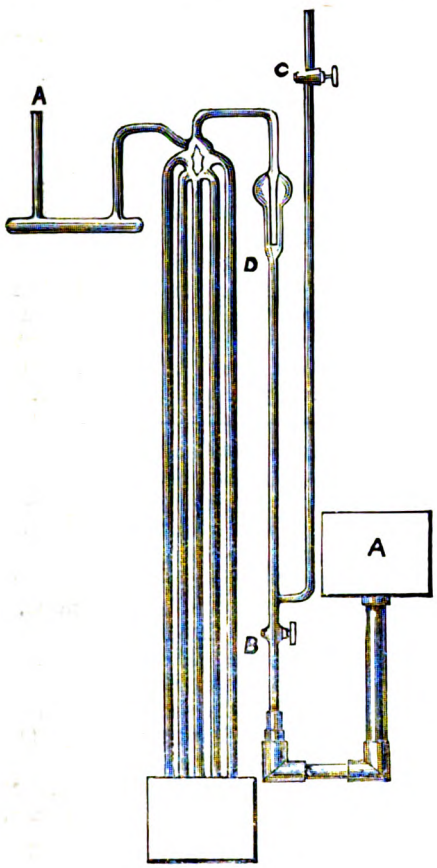

FIG. 13.

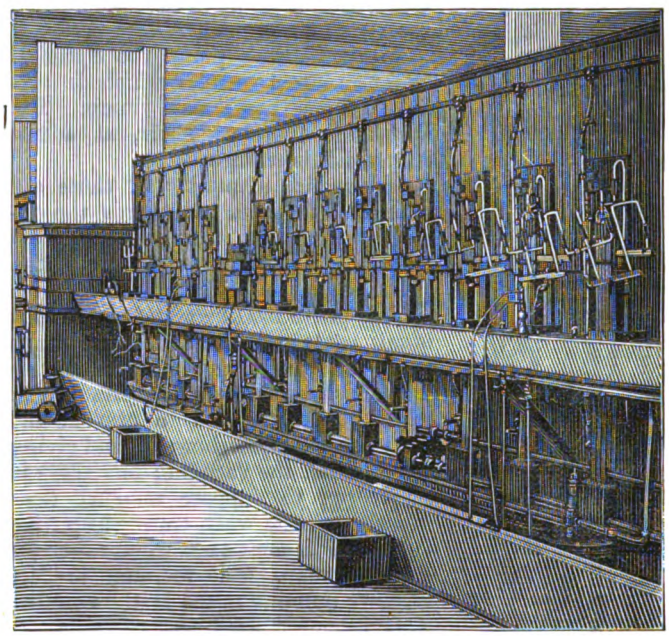
be as well to describe it. A is the reservoir of mercury which really supplies several pumps, B is the tap for regulating the flow of mercury, C is a tap on the pipe leading to the mechanical exhaust. An air trap is inserted in the mercury supply tube. Instead of a contraction the mercury passes through five little nozzles or jets, so that it flows in five little streams into the fall tubes or shafts. The top of each tube is large for a few inches, and then the Sprengel shaft proper begins. This is about 40in. long. A tube leads from the pump to the phosphoric tube, which is connected to the lamps. The lamps are not shown. The lower ends of the shafts dip into mercury in a second reservoir. The lower reservoirs of several pumps overflow into one large tank. The mercury is elevated from this to the upper reservoir by a force pump. The force pump is made with no brass exposed to the mercury, and the reservoirs and pipes are made of iron. The force pump has many disadvantages. It dirties the mercury, and it requires a shaft to be brought into the pump room. It is also expensive, and likely to get out of order. The archimedian screw has also been used. Such an elevator consists of a spiral pipe of hard rubber or gutta percha, fixed round a wooden centre piece. This is rotated in an inclined position, with the lower end dipping into mercury, and a shelf to catch the mercury as it comes out at the top.

The writer has introduced the system of raising the mercury by means of compressed air. This has the great advantage that there is no machinery in the pump room, as an air compressor in the engine room is all that is necessary. For raising mercury for a system of Sprengel pumps a closed tank is arranged a little below the level of the overflow from the pumps, so that the used mercury flows into it gradually through a pipe with a non-return valve, which is made entirely of iron. A delivery tube goes from the bottom tank to the reservoir. Compressed air is allowed to flow slowly into the tank, its flow being regulated by a small tap. There is a small valve opening to the air, so that when the valve is open the air from the compressor escapes; but when it is closed the pressure is exerted. This valve is controlled by a float, which rises and falls with the mercury in the tank. When the mercury begins to flow in, the float is at the bottom and the valve is open; when the tank is filled the float suddenly shuts the valve, and the pressure forces the mercury up the delivery tube to the upper reservoir; when the tank is empty again the float suddenly opens the valve and lets the air escape. This elevator was used on a large scale in the Swan lamp works fitted up by the writer in Boston, United States of America. It worked very well. It would have been simpler, however, to have dispensed with the valves and floats, and to have made the flow of compressed air intermittent by an automatic



View of Boston Pump Room.

arrangement such as that used in the writer's pumps, to be described presently. The delivery tube must not be made to rise directly from the tank, as, if it did, when the tank was emptied, the air would force the last of the mercury through with a rush, and would blow through. The delivery tube is therefore led down a foot or so, so that there is an extra head of mercury to resist the air pressure when the tank is emptied.

The above engraving shows part of one side of the pump room fitted up in Boston in 1882. A long partition runs along the centre of the room, and to this 100 pumps are fixed, 50 on each side. The iron pipes are for the air pressure, gas, and vacuum. The pipes were iron gas barrels, and so perfectly was the work done that, in spite of the innumerable joints and connections, on the first trial the Bourdon gauge in the engine room showed a vacuum of 30, and after being left all night the gauge still stood at 30. This sort of workmanship might be copied with advantage by our English plumbers. A Knowles steam vacuum pump was used, with a 10in. cylinder. The compressed air

Digitized by Google

was supplied by a small compressor originally made for driving a rock drill. The pumps seen in the engraving are five shaft Sprengels. Each pump has two phosphoric tubes. The shafts are not sealed to the pumps, but are connected by little pieces of thick walled rubber tube, which have been steeped in glycerine, and the branch tubes on which the lamps are sealed are connected in the same way. This method of making joints is bad, and had to be abandoned. Each pump is fixed to its own board, so that when it goes wrong it can be taken down and another put in its place without delay. All the parts of the pumps are made to gauge, so that the pumps are interchangeable. There is an elevator for every sixteen pumps, of which eight are on each side of the partition. A hand blow-pipe, with flexible tubes, is arranged with gas and air supply. The air was taken from the high-pressure pipe, as it was not worth while to lead a special pipe from the glass-blowers' supply. Under the pumps there is a trough to catch any mercury that may be spilled by the breakage of a pump. The whole floor is also covered with linoleum, which is turned up at the walls, so that any mercury that is spilled may be swept up without loss.

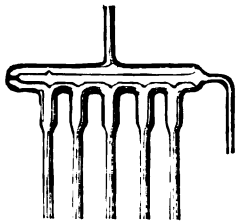


FIG. 14.

Fig. 14 shows an arrangement of the jets—of a five-shaft Sprengel that has the advantage of being much easier to make than Mr. Gimingham's form. It was designed by Mr. Proctor, who was the writer's assistant in Paris in 1882. The horizonal jet tube should have a little hole on the upper side of it, otherwise air is apt to collect and spoil the vacuum when nearly complete.

In Mr. Stearn's pump the Sprengel exhausts into a vacuum which is produced by a mechanical pump. The shafts are therefore short, as a few inches' fall is enough.

In practice a number of these are connected together as regards the elevating system, so that a pump room has a number of groups of eight or ten pumps each.

This pump has the advantage that it is self contained, and that the mercury is not allowed to get dirty, as it does when it flows through a system of iron pipes. It is also said to prevent the mercury from absorbing air, and giving it off under the vacuum; but there is no reason to suppose mercury does absorb air, even when churned up with it, as it is in some cases when raised by a force pump. The mercury in Mr. Stearn's pump is raised by the vacuum. This is not a good way of raising it, as a vacuum is more difficult to manage than compressed air. If compressed air were used in this pump, however, it would have to be made much longer, and that would spoil its compactness, which is its chief charm. The short-shaft principle is due to Poggendorff, who devised a sort of rough short fall Geissler pump; but the introduction of it is due to Mr. Stearn who re-invented it.

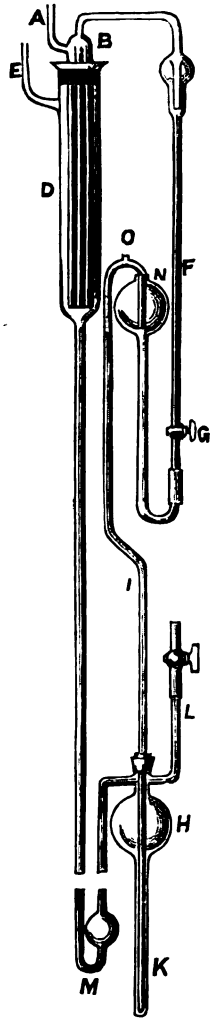

FIG. 15.

Figure 15 shows a modification of Mr. Stearn's pump devised by the writer. This pump was in actual use some time, but it is here described to show how a pressure-elevator may be applied to the Sprengel pump. A is a tube from the lamps and phosphoric tube, the jets are inside at B. There are three shafts about 10in. long. The shafts are enclosed in a wide tube, which has a taper mouth, which is closed by a rubber stopper which fits B. The wide tube D is connected with a mechanical exhaust by the tube E, and when it is exhausted the mercury rises and covers the ends of the Sprengel shafts. When the tube D is exhausted and the tap G open the mercury runs up F and down the Sprengel shafts, and the overflow runs into H. H has a tube I passing through an air-tight stopper in the neck and passing down nearly to the end of the tube K. L is a small tube connected to the intermittent air pressure. When H is nearly full of mercury the pressure comes on. It forces the overflow from the pump back down M till there is enough back pressure to prevent its being forced any further. It also forces the mercury up tube I into the upper reservoir N; the long tube K prevents the whole of the mercury being forced out of I, by producing an opposing head of mercury; otherwise the last of the mercury would be blown round violently, and the compressed air would escape. When the air pressure is taken off, the mercury in M rises and flows into H again, and the mercury in the tube I falls. The opening at O prevents any siphon action which might otherwise occur, as the tube is turned down into N to prevent the mercury splashing.

The drawback to this form of pump is that if the vacuum in D is broken or even reduced a little, the mercury in the shafts is taken round into the phosphoric tubes or into the lamps. The Sprengel part of it is also a little difficult to make. This elevator can easily be applied to any ordinary Sprengel pump, as the tube D may be low down and may thus be open to the air. The writer has made a pump for experimental use in which D was itself the bulb of a Geissler pump; but there is no advantage in combining a Geissler and a Sprengel.

The writer devised a form of elevator some time ago which is interesting as a curiosity. It consists of a sort of inverted Sprengel pump. The top is exhausted and air is admitted through a regulating tap at the bottom in such a way as to carry up plugs of mercury. This works well, but the use of the vacuum is an objection. It might be used with compressed air, but the methods already described are better.

Lightning Conductors for Gasworks.—The destruction by lightning in January last of the large chimney at the gasworks at Fécamp, which was accompanied by several extraordinary circumstances, will be within the memory of some of our readers. The chimney was not provided with a lightning conductor, and in a paper describing the occurrence which was read before the French Society of Civil Engineers, the extraordinary opinion was expressed that such protection would, on this occasion, have been useless. M. Colladon thereupon communicated to the President of the Society a statement to the effect that chimneys in gasworks should always be provided with lightning conductors fitted with powerful tapes for the safe conveyance to earth of heavy charges of electricity. He stated that the destroyed chimney at Fécamp, which was 30 metres high, was built upon a foundation more or less humid from the vicinity of the sea, and containing numerous gas and water mains. In the neighbourhood there were also deposits of coal and coke, the whole forming an admirable ground connection. Under such circumstances, therefore, it was especially desirable that the chimney should be provided with a good lightning conductor connected to earth with special care. M. Colladon instanced a case at the Geneva Gas Works, where a chimney, surmounted by a heavy iron cap terminated in a pointed rod of platinised copper. This rod was in connection with a conducting cable, formed of six strands, each of six tinned-iron wires 2 millimetres in diameter. The cable descended to a depth of 3 metres below the surface of the ground, where it was doubled in several convolutions, which, even in summer, were immersed 2 metres in the waters of the Rhone. In July, 1877, however, the point of the conductor was struck and fused by lightning. At a height of 3·5 metres above the ground, a portion of the charge left the conductor, and spread along the ironwork of the roof of a shed built against the retort-house wall, after which it pierced this wall, which is 60 centimetres thick, displacing a block of stone in the way, to attain the iron gas-pipes which served to light the interior of the retort-house, whereby it finally escaped to earth. Since this event the cable has been supplemented by a better conductor,

ROWAN'S ELECTRO-MAGNETIC MACHINE TOOLS.

It is often of great convenience to be able to use certain tools in positions where it has hitherto been difficult to convey energy. Of late years the use of hydraulic machinery has, to a certain extent, enabled apparatus to be used in such situations, but it does not fully supply the requirement. Attempts have been made to use electricity for the purpose, and one of the most successful of these is to be found in the apparatus designed by Mr. Rowan, intended more especially for ship work; but of course the apparatus is useful for many other purposes.

The illustrations given on another page are sufficiently exhaustive to explain themselves, and will therefore need little description.

Figs. 1, 2, and 3 show arrangements of framing for carrying and guiding tools. Fig. 1 shows an elevation of frame, carrying a drilling or other machine, and traversing vertically by means of the screwed guides at each side; the machine moving laterally on the horizontal bars or guides of the frame, on which it is carried by a saddle or other arrangement. The frame is attached to the work either by electro-magnets, as shown on the left of the illustration, or by bolts, as shown on the right. This arrangement permits of a considerable area of work being embraced without altering the position of the framing. Figs. 2 and 3 show a plan of a similar frame attached to the side plating of a ship, which is shown in section, alternative methods of attaching the framing being shown at right and left of the figure. At A an electro-magnetic holder-up is shown in connection with a steam riveter, held only by the framing; at B an electric drilling machine, having in addition its own holding-on magnets, is shown, and at C an electric riveter and holder-up, having also their own holding-on magnets, are shown, all moving on the same framing. Fig. 2 shows a plan of guide bars for carrying and shifting the position of machines in such places as under the bottom of a ship, &c., where lifting tackle cannot be applied conveniently.

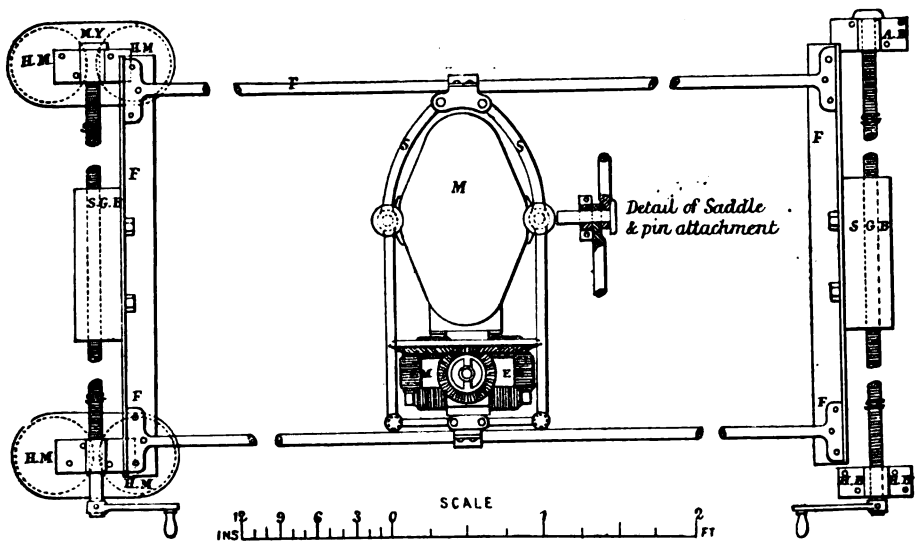

FIG. 1.—Framing for Traversing Tools.

Fig. 4 shows an elevation—partly in section—of an electro-magnetic riveter (the motor being omitted), having holding-on magnets, and a spiral or volute cam, which, through an anti-friction roller on an arm, lifts the hammer rod against a spiral spring, which, when released by the cam, operates to produce the blow of the hammer. The spiral spring is compressed between the hammer head and a disc or plate working in a circular guide box, its position, and consequently the amount of compression given to the spring, being regulated by two screwed spindles working through the top of the guide box, and moved by gearing (omitted in this figure but shown in Fig. 5.)

Fig. 5 shows a similar riveter operated by means of a helical cam (shown in side elevation at Fig. A) which works in the line of the hammer rod between cross heads connected by four rods, to the lower of which cross heads the hammer rod is attached.

Fig. 6 shows in front elevation and in side elevation in section, one form of an electro-magnetic holder-up for riveting. It has a curved arm with a supplementary bolster for application to rivets under reverse-bars of ships' frames or in confined spaces.

The pressure on the rivet head under the main bolster is applied by a strong screw worked by a hand wheel after the holding-on magnets have taken their grip of the plating, and a steel or other spring at the back of each bolster permits of the flattening of the rivet head during riveting, being compensated.

Fig. 7 shows one form of electro-magnetic drilling machines with a single drill spindle, the motor being omitted. Feed gearing is shown, which may be worked by hand or by means of spur gearing.

Fig. 8 shows another arrangement of drilling machine for either a single drill spindle, capable of being traversed horizontally along the frame to which the motor is attached, or it represents a cross-section of a multiple drilling machine, as shown in elevation in Fig. 6 and in plan in Fig. 10, which shows auxiliary holding-on magnets at the back of the framing, but it is not absolutely necessary to use them.

Figs. 11, 12, and 13 show different forms of machines for caulking and chipping.

At A and B in Fig. 11 the tool is shown actuated by an electromotor through gearing, lifting cam, and spring, as in the riveting machine. The other views show (in section at C, Fig. 11, and in elevation, Fig. 13) an arrangement of solenoid coils for producing the necessary effects. At A, Fig. 11, and in both Figs. 12 and 13 each tool is held or supported by its own holding-on electro-magnet, to which it is attached by an arm and traversing screw, and either ball and socket joint, or swivel pin, which allow its position and angle to be altered at will.

At B and C, Fig. 11, the tool frame is arranged to allow it to be used in conjunction with a frame or guide similar to that shown at Fig. 2.

UNDERGROUND TELEGRAPHS.

Mr. FLEETWOOD'S paper the other evening at the Society of Telegraph-Engineers, although interesting of itself and valuable, perhaps, to those whom it may concern, was disappointing, we suspect, to most of the members present because of the very limited scope of its treatment. A paper on Underground Telegraphs that deals only with subterranean wires in cities and towns is like a paper on Submarine Telegraphs dealing only with submerged cables under channels and rivers. Naturally Mr. FLEETWOOD devoted his time chiefly to a branch of the subject with which he has been associated more closely, perhaps, than any other person living; but something more was expected from the title of his paper, and that something was almost wholly lacking. We say almost, because, apparently with a view of meeting this objection, Mr. FLEETWOOD supplied some very instructive facts with reference to ancient underground cables which he had disinterred in the course of his excavations within the metropolitan area, and which exhibited some features of durability and electrical efficiency that were of a highly encouraging nature. In some instances even the long-distance underground wires of forty years ago, when recently brought to light, were comparatively perfect, or at all events had failed more because of want of care in laying them down than because of any defect in the materials employed for insulation. If the same condition may be anticipated of the ingredients made use of during the last ten or twenty years, with all the improvements and careful superintendence which experience has taught us to be necessary, the Post Office underground wires will have a very long life indeed. But even on this point the paper was not so explicit as one could have wished; and a direct question on the subject addressed to the author during the discussion which followed was, perhaps through missing the point of the questioner, not quite satisfactorily answered. It seems to be the habit of British Post Office officials to assume that everybody will take for granted the work done by their Department to be as perfect as man can make it. This may be the case, but the assumption is liable to be questioned by outsiders, and their reasonable curiosity, as well as their perhaps unreasonable incredulity, should be satisfied.

On the whole, we think there is room for another paper on Underground Telegraphs, and preferably from a quarter less trammelled by official reticence or prejudice. We want to know more about modern underground wires of considerable length, if not in this country, in other countries; at what rate they are capable of being worked with appliances and operators such as we can command in England; whether those wires develop faults as frequently as overhead wires; and what is the probable life of such wires. The cost we do not care so much about, because efficiency and permanency are the chief things to be aimed at; and upon these two points there seems to be a divergence of opinion even among Postal Telegraph officials themselves. Mr. FLEETWOOD stops short just where we expect him to begin, illustrating our remark about official reticence; while Mr. PREECE drops some gratuitous disparagement which is a sample of what we mean by official prejudice. The first-named officer said nothing in his paper on the question, the vital question, of long underground wires—a very significant omission, seeing that he has evidently formed a very decided opinion on the subject. When his official chief expressed an opposite opinion the subordinate firmly but respectfully replied that he believed Mr. PREECE would change his mind. Plainly, one official is confident he could easily lay wires underground from London to Edinburgh that would work as well or better than the overhead wires, whilst equally plainly another official would rather he did not say so—at all events not in public. On this delicate question the higher official has, in all probability, a perfectly open mind, which is at present revealed in his observation that if Parliament will give the Postmaster-General the two-and-half millions necessary to carry out the work, our great centres of commerce and industry will be telegrapically connected by wires laid underground. Indeed! Then what are we to say of the subsequent contention that subterranean wires are electrically so many times inferior to aërial wires? Until we heard about the two-and-half millions we had accepted this electrical dogma as gospel, and have preached it ourselves in good faith. But we cannot suppose that the Electrical Branch of the Post Office Telegraphs would countenance or consent without protest to a scheme of vast expenditure handicapped beforehand with such an electrical dead weight. Whenever we have urged the electrical difficulty in conversation with the non-scientific public their invariable rejoinder has been, "Oh, but you can surely get over that." We begin to think the public may be right after all.

Two millions and a-half is a formidable estimate however, and is suggestive of indefinite postponement. Now, although we have resisted the popular and ignorant clamour for a general underground system whenever the overground wires are interrupted by storm, we have on the other hand advocated certain alternative routes for military as well as commercial reasons, and especially in connection with the international cables, being safely lodged underground. But to talk of two and a-half millions of money being required for this purpose puts the suggestion almost outside the sphere of practical politics. We have heard it hinted that this big figure has been named only to frighten somebody, and effectually cure him of his fancy. Whoever that somebody may be, we trust he may see for himself that work of that kind may be done gradually, and that if he is content with less ambitious projects he can practically have what he desires at a far less prohibitive price. Meanwhile it is, we think, to be regretted that a prominent engineering officer of the Post Office should give currency to an extravagant estimate calculated to have the effect of depriving the public altogether of what they may reasonably demand

Digitized by Google

simply because they have demanded more than they actually need.

We cannot leave this subject without according our warmest approbation of the remarks which were incidentally let fall by Colonel WEBBER with reference to overhouse telephone wires. A more sensible and businesslike statement of the case for gradually laying these wires under the streets it would be impossible to have made. Pointing out the almost intolerable nuisance which these wires have grown to be in the metropolis, and the obvious fact that a time must soon come when the public will stand no more of them, he advised that a reserve fund should be accumulated by the telephone companies for the purpose of constructing an underground system similar to that of the Post Office, and ready against the time when patents and public patience alike have expired. That time is not far distant, and the sooner Colonel WEBBER'S advice is acted on the better. Over and over again we have proffered the same advice, only to incur the implacable ill will of the responsible managers of at least one great metropolitan telephone company. Colonel WEBBER, having been himself associated with the enterprise, will be suspected of no journalistic or other prejudice against the overhouse system; and it may be hoped that his words will reach the eyes of the present holders of London telephone shares, if the ears of the managers continue deaf to his friendly remonstrances. Mr. FLEETWOOD'S paper at least was conclusive as to the practicability—and incidentally also as to the economy—of underground wires for telephony not less than for telegraphy. What the Post Office have done a Telephone Company could do; and as to the cost, it has been grossly and wilfully exaggerated. In the second place it must be incurred sooner or later, and the later it is the heavier it will be. It was one of the defects of Mr. FLEETWOOD'S paper that it told us nothing about cost; but although it may suit the Post Office to stagger us with alarming estimates, they do not expend their money on the same magnificent scale; and as their metropolitan wires are nearly all underground, we may safely argue that the process was originally calculated to prove economical in the long run.

CORRESPONDENCE.

REGULATION OF SERIES-WOUND TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of April 9th, in an article on regulating series-wound transformers, you describe the interesting work of Messrs. Sharp and Kent, of Westminster, their plan of operations being the substitution of what you term "induction rings" for lamps in the secondary line of induction coil lines in series.

A point is also made that the energy expended in a coil which replaces a lamp is in reality quite trifling in amount, &c.

I enclose with this letter copies of three United States patents, which were filed March 19th, 1883, May 21st, 1884, and May 23rd, 1884, respectively. An inspection of these patents will show conclusively that they fully disclose the mode of regulation in an alternating current system of any kind, consisting in the substitution of self-inductive coils, or what I have termed "reactive coils" for lamps, the coils being constructed to have a very low resistance, and with a large coefficient of self-induction.

In the earliest of the patents, namely, that filed March 19, 1883, there occurs on line 45 the statement, "I use in my system an alternating line current supplied to the circuit by any suitable generator, or by an induction apparatus whose primary is fed by any suitable generator;" and in line 57 thereafter the statement occurs, "In connection with the lamps or other working resistances of the system I provide a suitable electric reaction device, such, for instance, as an electro-magnet and reactive coil consisting of a bundle of iron wire or other suitably divided or otherwise constructed core, surrounded by a coil of insulated wire, and whose purpose is, when a lamp, motor, or other device is removed from the circuit, to convey only that current that would have kept the lamp burning. The resistance of the reactive coil is made very small, by preference, and it acts not as a substituted resistance but as a real counter electromotive force generator;" and further, in line 81, the description continues, "This device operates after the well-known manner of an electro-magnet in an electric circuit to set up what is known as an "extra" or "counter" current, whose tendency is to oppose a current sent into the coils at the moment it begins to flow." One of the concluding clauses of the specification I may be permitted to quote, as it bears on the question of loss of energy. It is, "In the system as herein described any lamp or lamps may be extinguished by simply replacing it, by its reactive coil or condenser or similar device, and without the loss of energy of current such as occurs when the lamp has a resistance substituted therefor."

The claims, though all relating to this feature of a substituted reactive coil, may be typified by quoting only one—namely, the first. "The combination with an electric lamp or other translating device included in a circuit with a source of rapidly alternating or reversed currents of an electro-magnetic self-inductive reaction device or its described equivalent, normally out of action, and having a definite or determinate counter electromotive force capacity, adapted or adjusted, as described, to permit it, when substituted for a lamp or other device to oppose or check the passage of the alternating or reversed currents to a degree corresponding to the opposing effects arising from the electric resistance in the translating device."

In my patent filed May 21st, 1884, which is for a system of distribution using a continuous line current commuted through primary coils in series for the generation of secondary currents feeding local lines of lamps which are in multiple arc or in parallel, I refer to Fig. 8, which is described in the specification as follows:—

"Fig. 8 is a diagram illustrating a means whereby lights may be cut out in such a manner as not to affect each other's brilliancy." Then, further, in the description of the said figure occurs the paragraph, "Ordinarily the removal of a light or lights or other apparatus connected with a secondary would demand the readjustment of the speed of the commutator or of the relations of the coils or core in order to avoid any undue flow of current to the remaining lamps. To obviate this a small reactive coil of low resistance wound upon an iron core, indicated at R, Fig. 8, may be employed and combined with a suitable electric switch, whereby upon the cutting out of a lamp the said coil may be made to take its place. I mean by 'reactive coil' a coil whose opposition to the passage of alternating currents through it is due simply to its counter electromotive force tendency, and not to its resistance. The coils R R of Fig. 8 are of this nature, and since the secondary currents are alternating in character the substitution of one for a light extinguished leaves the relation of the electromotive forces to the remaining lamps constant, so that they do not change their brilliancy."

Claim 4 of this patent bears directly upon this subject matter. It is—"In combination with an induction coil, a local line connected with its secondary and containing translating devices and reactive coils, having switches, whereby reactive coils may be substituted for lamps extinguished."

The remaining patent, namely that filed May 25th, 1884, I send merely as illustrating another use of the reactive coil on alternating current circuits.

The applicability of the reactive coil according to the method described in these patents and its efficiency as a lamp substitute, with the saving of energy on such circuits, was proved by practice with this arrangement in a variety of ways. The identity of the device, which I have termed a "reactive coil to the induction ring," as used by Messrs. Sharpe and Kent in its functions as a lamp substitute, needs no further proof than a mere inspection of the copies of the patents sent. In fact, I may here make the broad statement that I believe it to be

Digitized by Google

true that with any arrangement of alternating current circuits involving a connection of incandescent lamps in series, or in parallel, or in series multiple, or in multiple series, or whether induction coils are used in series, or in multiple, or in multiple series, or in series multiple, the reactive coil substitute may be used wherever a lamp or lamps are extinguished, and a proper balance of the distribution of the current effected thereby, so that the remaining lamps are undisturbed in brilliancy, and that a corresponding saving of energy, within a few per cent., will take place in proportion to the number of lamps extinguished in the system.—Yours, &c., ELIHU THOMSON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On pages 35-36 (*Electrician*, May 20, 1887) there is a note "On the Regulation of Series-wound (? Series-working) Transformers," with several tables.

Table I. gives the resistance of the external circuit, also watts expended in the rings when the number of these is varied; and on working through the figures in this table these two columns appear to me to be incorrect.

The resistance of each lamp is 160ω, and that of each ring 1ω.

From these data and the further data that the virtual resistance of each ring is 160 watts so that the current is always ·625 ampere, I calculate the table thus:—

Lamps in Circuit.	Rings in Circuit.	Resistance of external circuit.	Watts expended.		Watts expended in same circuit by steady E.M.F. of 100 volts.
n.	*m.*		Lamps.	Rings.	
16	0	10	1,000	0	1,000
12	4	·253	750	1·66	3,930
8	8	·124	500	3·13	8,050
4	12	·0826	250	4·80	12,100
1	15	·0661	62·5	5·88	15,100
0	16	·062	0	6·25	16,000

Column III. is calculated by formula $\frac{lr}{l+r}$, where $l=\frac{160}{n}$ and $r=\frac{1}{m}$.

Column IV. is calculated by formula $W=C^2Rn$, where C = ·625 ampere and R is 160 watts for each lamp. $W=C^2Rm$ where C = ·625 and R = 1 for each ring.—Yours, &c.,

LL. B. A.

[We are obliged to our correspondent for having called our attention to the point in question. In reality, however, the discrepancy belongs to some of the figures *in the first two columns only*, which seem to have been accidentally misplaced when the published figures were abstracted from a more complete table which had been compiled by the writer of the article. Our correspondent queries the use of the term "Series-Wound Transformer," but there seems to be no reason why the analogy of the terms in common use to describe the field-windings of dynamos should not be followed in this case.—ED. *E.*]

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We noticed lately in your pages that in estimating for some electric lighting electrical engineers were so hopelessly at variance that those who received their estimates decided to go back to gas. We have just heard to-day of a parallel case here in the north. A committee who had charge of lighting arrangements deemed it unwise to adopt a light about which so little was known, even by those who made a business of supplying it. As one of the competing parties we of course are of opinion that our estimate as to the number of lights, their distribution, and their cost, is right, and that we suffer because other competitors have erred; but the trouble is that the other competitors all probably hold a similar opinion as regards their own proposals.

What ought to be done? Architects and others in determining the number of gas jets to be fitted in a building are for the most part guided by experience and rule of thumb. But the electric light is more unfamiliar, and very vague ideas are abroad as to the area which a glow or an arc lamp can illuminate. It would be well to have a normal unit standard which might be used by engineers, and understood by architects, say so many cubic feet per candle-power, or a brightness over floor, or roof, or work tables of a standard candle at a fixed distance. Such units are used daily by experienced lighting engineers. What is wanted is that those units should be placed before architects and mill owners in a form readily comparable with their past experience, so that in asking for estimates they may be able to give a common basis to go upon. But the amount of light to be provided is only one thing among many on which opinions may differ. Perhaps the safest plan in most cases is to entrust the drawing up of a scheme and specification to a competent consulting electrician, who is, or ought to be, without direct or indirect pecuniary interest in any special form of apparatus. This would ensure a good and reliable plan and workmanship, although not necessarily the very best, for it fails to enlist the experience and ideas of those daily engaged in carrying out practical work. Whatever method is adopted, security is, after all, only to be obtained by the buyer personally knowing the men he deals with. If a man whose skill and care and honesty can be relied upon is not to be found, there is nothing for it but to submit to all the dangers and defects of estimating, and give the work into the hands of the people who have chosen to put in the cheapest material or undercalculated the necessary outlay.

We simply wish, however, to elicit opinion on this large subject, not to formally and fully discuss it.

Before ending we would like to select and give one example of the uselessness of giving away any ideas while still uncertain of being entrusted with the work at all. In April, 1886, we wrote (through the general manager) to the directors of the N.B. Railway Company, Edinburgh, suggesting several ways of lighting the trains or tunnels of their new underground line at Glasgow. After giving approximate prices of various methods of constant and intermittent tunnel lighting, we proceeded to schemes for train lighting. The first method being "each train complete in itself"; the second, "current derived from fixed engine and dynamo;" "carriages to be fitted up with separate wires, lanterns, connectors, &c., at a cost of, say, £4 per carriage;" then a named sum of further expenditure "would provide all appliances save a small engine and boiler (which, in our other proposals, was to be provided by the railway company, who already had sets of these which might be available), necessary for the automatic lighting up of these lamps when the train entered a tunnel and extinguishing them when the train emerged." Our third method was to use the ordinary compressed gas for train lighting, but arranged so that the guard could electrically light or extinguish instantaneously the whole train, and so on.

This "second method" was at that time a perfectly new suggestion for train lighting, and although non-technically described, was yet sufficient to have enabled any intelligent electrical workman, acquainted with the usual methods of transmitting electricity from fixed conductors to moving carriages, to carry out the work with more or less skill in mechanical detail. On May 17th of same year Mr. Carswell, a gentleman connected with the North British Railway Company's offices in Edinburgh, patented an almost identical system, and it has been adopted by that company, and the work carried out without our being asked to quote for those parts of the material of which we are manufacturers.—Yours, &c., ANDERSON AND MUNRO.

136, Bothwell-street, Glasgow.

THE LIGHTING OF TURIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Pickering has called in question the correctness of the information contained in the note you published in regard to the failure of the Gaulard and Gibbs system in Turin. The following extract, published independently by the Italian journal *L'Elettricita* (a copy of which I herewith forward), not only confirms the correctness of the original note, but gives additional information that may be of interest and furnish a clue to the actual cause of the failure:—

"The Gaulard transformers adopted by Messrs. Bellani

Digitized by Google

Brothers, contractors for the electric lighting of a part of Turin, did not give the results that were expected in the public service.

"For the illumination of private parties, the contractors, instead of Gaulard transformers, installed the dynamos and transformers of Messrs. Zipernowsky and Déri.

"We have been informed that a large number of Gaulard transformers were found burned out and unfit for use, and Messrs. Bellani have decided to discontinue their employment for the public lighting. At the present moment the public service is secured by the Zipernowski-Déri system.

"The public illumination includes 80 incandescent lamps of 50 candle-power, and 3 arc lamps, all of which are run by the Zipernowsky-Déri system."

In addition, I have in my possession the results of tests made upon the Siemens cables before, during, and after the trials, which show that the failure must be ascribed to some other cause, considering, too, the fact that both systems used alternate currents, not differing greatly in electromotive force.

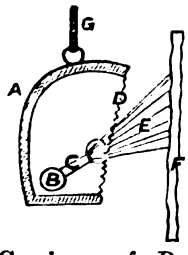
As the note in question contained no reference as to cause, but confined itself to facts, which Mr. Pickering has not shown to be untrue, I think he has no grounds for complaint.—Yours, &c.,

J. W. LIEB.

THE FIRE AT THE OPERA COMIQUE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was an eye witness of the catastrophe that occurred last night at the "Theâtre National de l'Opera Comique." It was about the end of the first act in "Mignon" when one of the gas jets in the cross light sputtered owing to a shock which that particular cross light received, due to some stage manipulation. The moment the light reached a sort of net decoration, in close proximity to the cross light, the net caught fire like ignited gun cotton. The decorations being so near the gas lights are always very warm and dry, so that they burn like tinder when lighted. The following is a little sketch in cross section, which shows how the fire originated:—



A is the iron frame of the cross light suspended by ropes G. B is the main gas tube, which has at regular intervals jets C, D is a sort of wire gauze, and F shows the decoration in front of the cross lights, E represents the sputter which ignited the decoration F, and caused the loss of so many lives and damage to property.

In a few moments the fire spread over the whole stage, and to-day the Opera Comique of Paris comes within the long list of such calamities which have occurred within the last few years, and reminds one of the Ring Theatre, Stadt Theatre in Vienna, the Arad Theatre and Szegedin Theatre in Hungary, the Nice Theatre, Rouen Theatre in France, and Alhambra in London. These are only a few of the principal ravages that our contemporary the gas light has been the cause of.

Had not the Cie. Continentale Edison been hindered from commencing their work last September, the disaster of yesterday would not have happened; but instead of receiving their contract last year they only received it a few weeks ago. They have been actively pushing their installations, and expected to commence electric lighting in July.—Yours, &c.,

FRANCIS JEHL.

25, Rue Jacob, Paris, May 26th, 1887.

SECONDARY BATTERY QUESTIONS IN BELGIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR, [illegible] statement which I have made as to the use of miniu[illegible] the construction of accumulators rests upon the auth[illegible] of the late Comte Du Moncel. When Du Moncel w[illegible] following paragraph there can be no doubt that his i[illegible]ion came from a reliable source. He says:—

"[illegible]t[illegible] avait bien pensé, *des ses premières recherches*, à abréger [illegible]e la formation, en déposant sur les lames de plomb [illegible] minium et en réduisant cette couche par le courant [illegible] . . . . mais l'adhérence de celle-ci était mauvaise et la couche déposée s'écaillait et finis sait par disparaître.

"Quand en 1881, on pensa à employer les accumulateurs pour l'eclairage électrique et les moteurs, M. Faure *reprit l'idée* de l'application de la couch de minium sur les lames de plomb, et pour maintenir l'adhérence, il enveloppa les lames recouvertes de minium dans des sacs de feutre." "Eclairage Electrique," Du Moncel, 1883, Vol. I., pages 56 and 57.

The problem which remained to be solved after M. Planté was merely to discover a satisfactory method of attaching the minium to the lead plate, and this problem, it is very certain, every one has a right to solve in his own fashion.—Yours, &c.,

YOUR CORRESPONDENT.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XL.

BY OLIVER HEAVISIDE.

(Continued from page 51.)

Preliminary to Investigations concerning Long-distance Telephony and Connected Matters.

Although there is more to be said on the subject of induction balances, I put the matter on the shelf now, on account of the pressure of a load of matter that has come back to me under rather curious circumstances. In the present article I shall take a brief survey of the question of long-distance telephony and its prospects, and of signalling in general. In a sense, it is an account of some of the investigations to follow.

Sir W. Thomson's theory of the submarine cable is a splendid thing. His paper on the subject marks a distinct step in the development of electrical theory. Mr. Preece is much to be congratulated upon having assisted at the experiments upon which (so he tells us) Sir W. Thomson based his theory; he should therefore have an unusually complete knowledge of it. But the theory of the eminent scientist does not resemble that of the eminent scienticulist, save remotely.

But all telegraph circuits are not submarine cables, for one thing; and, even if they were, they would behave very differently according to the way they were worked, and especially as regards the rapidity with which electrical waves were sent into them. It is, I believe, a generally admitted fact that the laws of Nature are immutable, and everywhere the same. A consequence of this fact, if it be granted, is that all circuits whatsoever always behave in exactly the same manner. This conclusion, which is perfectly correct when suitably interpreted, appears to contradict a former statement; but further examination will show that they may be reconciled. The mistake made by Mr. Preece was in arguing from the particular to the general. If we wish to be accurate, we must go the other way to work, and branch out from the general to the particular. It is true, to answer a possible objection, that the want of omniscience prevents the literal carrying out of this process; we shall never know the most general theory of anything in Nature; but we may at least take the general theory so far as it is known, and work with that, finding out in special cases whether a more limited theory will not be sufficient, and keeping within bounds accordingly. In any case, the boundaries of the general theory are not unlimited themselves, as our knowledge of Nature only extends through a limited part of a much greater possible range.

Now a telegraph circuit, when reduced to its simplest elements, ignoring all interferences, and some corrections due to the diffusion of current in the wires in time, still has no less than four electrical constants, which may be most conveniently reckoned per unit length of circuit—viz., its resistance, inductance, permittance, or electrostatic capacity, and leakage conductance. These connect together the two electric variables, the potential difference and the current, in a certain way, so as to constitute a complete dynamical system, which is, be it remembered, not the real but a simpler one, copying the essential features of the real. The potential difference and the permittance settle the electric field, the current and the inductance settle the magnetic field, the current and resistance settle the dissipation of energy in, and the leakage conductance and

Digitized by Google

potential difference that without the wires. Now, according to the relative values of these four constants it is conceivable, even, I should think, by the eminent scienticulist, that the results of the theory, taking all these things into account, will, under different circumstances, take different forms. The greater includes the lesser, but the lesser does *not* include the *greater*.

In the case of an Atlantic cable it is only possible (at present) to get a small number of waves through per second, because, first, the attenuation is so great, and next it increases so fast with the frequency, thus leading to a most prodigious distortion in the shape of irregular waves as they travel along. Of course we may *send* as many waves as we please per second, but they will not be utilisable at the distant end. This distortion is a rather important matter. Mere attenuation, if not carried too far, would not do any harm. Now the distortion and the attenuation, though different things, are intimately connected. The more rapidly the attenuation varies with the frequency, the greater is the distortion of arbitrary waves; and if the attenuation could be the same for all frequencies, there would be no distortion. This can be realised, very nearly, as will appear later.

Now when there are only a very few waves per second, the influence of inertia in altering the shape of received signals becomes small, and this is why the cable theory of Sir W. Thomson, which wholly ignores inertia, works as a substituted approximate theory. But suppose we shorten the cable continuously, and at the same time raise the frequency. Inertia becomes more and more important; the theory which ignores it will not suffice; and carrying this further, we at length arrive at a state of things in which the old cable theory gives results which have no resemblance whatever to the real. This is *usually* the case in telephony, as I have before proved. It is always partly the case, viz., for the very high frequencies, and it may be true, and practically is sometimes down to the low frequencies also. I have shown that the attenuation tends to *constancy*, as the frequency is raised, except in so far as the resistance of the wire increases, and that at the same time the speed of the waves tends to approximate to the speed of light, or to a speed of the same order of magnitude, which is the only speed which can, I think, be said, even in a restricted sense, to be the "speed of electricity." But if the dielectric be solid, there must be some uncertainty about what this speed is, for obvious reasons, with very high frequencies. The speed of the current is *never* proportional to the square of the length of the line. I swear it.

Within the limits of approximately constant attenuation the distortion is small. This is what is wanted in telephony, to be be good. Lowering the resistance is perhaps the most important thing of all. Other means I will later mention. What the limiting distance of long-distance telephony may be who can tell? We must find out by trial. We know that human speech admits of an extraordinary amount of distortion (never mind the attenuation) before it becomes quite unrecognisable. The "perfect articulation," "even different voices could be distinguished," &c., &c., mean really a large amount of distortion, of which little may be due to the circuit. There is the transmitter, the receiver, and several transformations between the speaker and the listener, besides the telegraph line. What additional amount of distortion is permissible clearly must depend upon what is already existent due to other causes. Even if that be fixed I see no legitimate way of fixing its amount by theoretical principles; the matter is too involved, and includes too many unknown data, including "personal equation." But this is certain, in my opinion—that good telephony is possible through a circuit whose electrostatic time-constant, the product of the total resistance into the total permittance, is several times as big as the recent estimate of Mr. W. H. Preece, and I shall give my reasons for this conclusion.

Increasing the inductance is another way of improving things. Hang your wires wider apart. The longer the circuit, the wider apart they should be; besides this, they may be advantageously raised higher. You can then telephone further, with similar attenuation and distortion. There is a critical value of the inductance for minimum attenuation ratio. It is from $L = Rl/2v$ to $L = Rl/v$, according to circumstances to be later explained; L being the inductance and R the resistance per unit length, l the length, and v the speed of waves which are not, or are only slightly dissipated, which is $(LS)^{-\frac{1}{2}}$ if S be the permittance per unit length. The resulting attenuation may be an enlargement, as I have before explained, due to to-and-fro reflections. This is to be avoided. I shall explain its laws, and how to prevent it. By this method, carrying it out to an impracticable extent, however, we could make the amplitude of sinusoidal currents received at the distant end of an Atlantic cable greater than the greatest possible steady current from the same impressed force, an unbelievable result. And, without altering the permittance or the resistance, we could make the distortion quite small.

There is some experimental evidence in favour of increasing the inductance (apart from lessening the permittance); though, owing to want of sufficient information, I do not wish to magnify its importance. I refer to the statement that excellent results have been obtained in long-distance telephony with copper-covered steel wires. Here the copper covering practically decides the greatest resistance of the wire; what current penetrates into the steel lowers the resistance and increases the inductance. Clearly, we should magnify this effect, and electrically speaking, it would seem that a bundle of soft-iron wires with a covering of copper is the thing, as this will allow the current to more readily penetrate, lower the resistance the most, and increase the inductance the most. But it is too complex a matter for hasty decision. We also see that the iron sheathing of a cable may be beneficial.

When we have little distortion, we get into the regions of radiation. The dielectric should be the central object of attention, the wires subsidiary, determining the rate of attenuation. The waves are waves of light, in all save wave length, which is great, and gradual attenuation as they travel, by dissipation of energy in the wires. There is the electric disturbance and the magnetic disturbance keeping time with it, and perpendicular to it, and both perpendicular to the transfer of energy, which is parallel to the wire very nearly. A tube of energy-current we may regard as a ray of light (dark, of course). (It is to such *long* waves that I attribute the magnetic disturbances that come from the sun occasionally, and simultaneously show themselves all over the world; arising from violent motions of large quantities of matter, giving shocks to the ether, and causing the passage from the sun of waves of enormous length. On such a wave passing the earth there are immediately induced currents in the sea, earth's crust, telegraph lines, &c.) But to return to the circuit. The attenuation ratio per unit length is represented by $\epsilon^{-R/2Lv}$, this being the ratio of the transmitted to the original intensity of the wave. This is when the insulation is perfect. These waves are subject to reflection, refraction, absorption, &c., according to laws I shall give. Of these the simplest cases are reflection by short-circuiting, when the potential difference is reversed by reflection, but not the current, and in the act of reflection the former is annulled, the latter doubled. Also reflection by insulation, when it is the current that is reversed, and potential difference unchanged; or, in the act of reflection, the first cancelled, the second doubled. But there are many other cases I have investigated.

I have also examined leakage. This is an old subject with me. An Atlantic cable is worked under the worst conditions (electrical) possible with high insulation; there is the greatest possible distortion. One megohm per mile or less instead of hundreds or thousands would vastly accelerate signalling. The attenuation factor is now $\epsilon^{-R/2Lv}\,\epsilon^{-K/2Sv}$ if K be the leakage conductance, and S the permittance per unit length. The attenuation is increased, but the distortion is reduced. This has led me to a theoretically perfect arrangement. Make $R/L = K/S$, and the distortion is annihilated (save corrections for increased resistances, &c.). The solution is so simple that I may as well give it now. Let V and C be the potential difference and current at distance x subject to

$$-\frac{dV}{dx} = RC + L\dot{C}, \qquad -\frac{dC}{dx} = KV + S\dot{V},$$

then, with equality of time-constants as described, the solution consists of two oppositely travelling trains

Digitized by Google

of which we need only write one; thus,

$$V = f(x - vt)\,\epsilon^{-Rt/L},$$

where $f(x)$ is the state when $t = 0$. The current is $C = V/Lv$. The energy is half electric, half magnetic; the dissipation is half in the wire, half outside. Change the sign of v in a negative wave. There is a perfect correspondence of properties, when this unique state of things is not satisfied between V solutions with $K = 0$, and C solutions with $R = 0$. This perfect system would require very great leakage in an Atlantic cable, and cause too much attenuation; but this perfect state may be aimed at, and partly reached. Are there really any hopes for Atlantic telegraphy? Without any desire to be over sanguine I think we may expect great advances in the future. Thus, without reducing the resistance or reducing the permittance (obvious ways of increasing speed), increase the leakage as far as is consistent with other things, and increase the inductance greatly. One way is with my non-conducting iron, which I have referred to more than once, an insulator impregnated with plenty of iron dust. Use this to cover the conductor. It will raise the inductance greatly, and so greatly diminish the attenuation, whilst the insulation resistance will be lowered, somewhat increasing the attenuation, but assisting to diminish the distortion, which the increased inductance does. The permittance change must also be allowed for. But I shall show that we can have practical approximations to almost negligible distortion in telephony, and that it is the reduction of R/L that is most important.

I have also examined the question of apparatus. We must stop the reflection, if possible, to prevent interference. In the perfect system this is also quite easy. The receiver must have resistance Lv and zero inductance. All waves arriving are then wholly absorbed. Similarly, to make the transmitted waves agree with the impressed force, Lv should be the resistance there (or else zero). Another remarkable property is that if the receiving coil be fixed in size and shape, whilst its resistance varies, then this same Lv is the resistance that makes the magnetic force of the coil a maximum. We cannot imagine anything more perfect. No distortion, and maximum effect. I shall show that these things may be fairly approximated to in telephony. It should be understood that in the perfect system we have nothing to do with what the frequency may be, whilst in telephony it is the high frequency that allows us to approximate to the ideal state.

Then there is the matter of bridges, and the nature of the reflected, transmitted and absorbed waves. The phenomena formally resemble those due to the insertion of resistance in the main circuit, except that the potential-difference and the current change places. Thus if R_1 be an inserted resistance, when there is no leakage and no resistance in the line $(1 + R_1/2Lv)^{-1}$ is the ratio of transmitted to incident wave. Now let there be no resistance inserted, but a bridge of conductance K_1; then the substitution of K_1 for R_1, and S for L gives us the corresponding formula. In the first case the reflected current is reversed, in the second case it is the potential difference of the reflected wave that is reversed. Now let there be both a resistance inserted and a conducting bridge, and choose $R_1/L = K_1/S$; then the reflected wave is abolished. Part of the original wave is absorbed in the bridge, and the rest is transmitted unchanged. This explains the perfect system above described.

I have also examined the changes made when the state is not perfect. The result is that a wave throws out a long slender tail behind it; and whilst the nucleus goes forward at speed v, the tail goes backwards at this speed. In time, if the line be long enough, the nucleus, which changes shape as it progresses, diminishes so as to come to be a part of the tail itself. It is then all tail. I will give the equation of the nucleus and tail. It is the mixing up of these tails that causes arbitrary waves to be distorted as they travel from beginning to end of the line. (But I have, in the above, usually referred to distortion as the change in the shape of the curve of current at a single spot.) There is residual reflection due to self-induction of receiver, even when the resistance is of the proper amount. The effect of diffusion in the wires is to make a wave with an abrupt front, which would continue abrupt, to have a curved front, and thus mitigate that perfection which only exists on paper. I shall also describe graphical methods of following the progress of waves, and of calculating arrival curves of various kinds, the submarine cable and oscillatory, approximate only, but very easy to follow. Other matters, perhaps more practical, but certainly duller, will find their place, if space allow.

(To be continued.)

MEASUREMENT OF THE DIFFERENCE OF POTENTIAL BETWEEN TWO METALS IN CONTACT.*

BY M. H. PELLAT.

We know that electroscopical measurements are unable to furnish us with the real difference of potential of two metals in contact, as they are complicated by differences of potential between the metals and the surrounding medium. Neither, on the other hand, does the phenomenon of Peltier (as was at one time believed) permit us to make such measurements. This has been shown by the author (*Journal de Physique*, Vol. IX., p. 122). In the absence of all positive data as to this quantity opinions are divided, certain physicists believing, with Volta, that its value is of the same order as that of the E.M.F. of the voltaic cell, others holding, with Maxwell, that it has a much smaller value of the order of thermo-electric E.M.F.'s.

I shall now describe an experiment which offers an exact solution of the problem in a particular case, and demonstrates the correctness of Volta's views.

We must first recollect that the surface of contact of two conductors may be compared to a condenser, the conductor at the higher potential being charged with a layer of positive electricity, opposed to which we have an equal quantity of negative electricity upon the surface of the conductor of lower potential, the value of each of these layers vanishing when the potentials are equalised.

Consider now the following apparatus:—Two vessels in communication, and full of mercury; the one, A, is wide, the other, B, is formed by a narrow tube—almost a capillary tube. A third vessel, C, of considerable width also contains mercury. In B and in C the mercury is covered with acidulated water, and these two vessels communicate by means of a siphon filled with the same liquid. Next two platinum wires connect respectively the mercury in C and that in B with the two terminals of a galvanometer.† Under these conditions, if we cause to vary, even very slightly, the extent of the surface of contact of the mercury in B with the acidulated water the galvanometer shows a current, of which the direction depends upon the *sign* of the variation. This phenomenon was discovered by M. Lippmann, and the explanation readily follows from considering the double electric layer on the surfaces in contact; the circuit being closed, the difference of potential between the accidulated water and the mercury B is constant. If, then, we vary the extent of the surface of contact the effect is the same as if we varied the dimensions of the plates of a condenser connected with a source of E.M.F. which maintained their difference of potential constant; the variation of surface necessitates, therefore, a current of charge or discharge. The direction of the current in this case shows that the mercury is at a higher potential than the acidulated water.

But I have considered that we might annul these currents, or even reverse their direction by introducing into the circuit an E.M.F. which should polarise in the required sense the mercury in the small tube B, without sensibly polarising the mercury in the large vessel C. For this purpose I have made use of an E.M.F. of known and variable value, and I find that when $e = 0{\cdot}97$ volt a variation in the extent of contact surface no longer produces a current. Under these conditions the double electric layer between the mercury B and the acidulated water is cancelled; that is to say these two liquids are now at the same potential. It follows that the difference of potential between the mercury C in the wide vessel (non-polarised) and the acidulated water has an absolute value of 0·97 volt. The number thus found is in accordance with that deduced by M. Lippmann from the E.M.F., which makes the capillary constant for mercury a maximum.

I have then proceeded to replace the pure mercury in all the tubes with a zinc amalgam, and I find that *the normal difference of potential between amalgamated zinc and acidulated water is nearly zero*, actually 0·02 volt in the same sense as for mercury.

Next I proceeded to make a cell, having for electrodes mercury and liquid amalgam of zinc separated by acidulated water, using as electrodes two platinum wires. The E.M.F. of this cell was 1·44 volt. But representing in general by X | Y the excess of potential of conductor Y over conductor X at the surface of contact, and

* Note presented to the French Academy of Sciences by M. Lippmann.

† [The connection with B is apparently made through the wide vessel A this being the only purpose for which A is required.—*Translator.*]

Digitized by Google

designating by P, M, A, L the platinum, mercury, amalgam, and acidulated water respectively, we have the equation of identity

$$E = P \mid A + A \mid L + L \mid M + M \mid P,$$

and as $E = 1{\cdot}44$, $L \mid M = 0{\cdot}97$, $A \mid L = -0{\cdot}02$,

we see that $P \mid A - P \mid M = 0.49$ volt.

Thus the true difference of potential of the platinum and the zinc amalgam at the contact P | A must be greater than 0·49 volt by the quantity for the platinum and mercury, P | M. For the rest, by Volta's law, we have

$$P \mid A - P \mid M = M \mid A,$$

that is to say, that the mercury shows an excess of potential over the amalgam in contact with it of 0·49 volt.

Thus, in this cell, the difference of potential between the liquid and the metal attacked is very nearly *nil*, whilst it is relatively large either between the liquid and the metal not attacked or between the two metals.

TRANSMISSION OF POWER AT THE MANCHESTER EXHIBITION.

Although much attention has been given to the transmission of power by electricity, and its application to electrical tramways and railways and the utilisation of water-power at a distance, the distribution of power by this means in workshops, factories, shipyards, and similar places has received comparatively little attention. At the same time there is no doubt that there is in this direction a very wide field for the use of electrical motors. This is especially so in those works where for various reasons the principal machines and tools are not driven from one common system of shafting, but have each an independent engine. Such is the case in printing works, where each printing machine is driven by its own engines; also in paper mills, in rolling mills, and in many shipbuilding yards, and other large engineering shops, where the heavier tools are necessarily distributed over a large area, and where it is important to have complete control over each individual tool. It is with the special intention of showing the applicability of electrical driving in these cases and its advantages that Messrs. Mather and Platt have designed their exhibit at the Manchester Exhibition. As a typical case, and one in which the conditions to be met are most stringent, they have chosen one of their ten-colour calico printing machines, for printing calico with ten colours simultaneously. If electrical driving can be proved to be advantageous and economical for complex machinery of this class, where a slow speed under the most perfect control and at the same time high efficiency are essential, there is no doubt about its applicability in other cases where the conditions are less exacting.

A large printing machine, similar to the one exhibited, would be driven under ordinary circumstances by a double cylinder diagonal engine, with cylinder 10in. diameter, 12in. stroke, running at about 180 revolutions per minute. The star wheel of the printing machine when printing at full speed runs at 12 or 13 revolutions only, it is therefore necessary to reduce the speed by gearing. But where a dynamo motor is used in place of the steam engine, the speed of the motor must be much higher in order to obtain good efficiency without unduly increasing the size and cost of the motor. The motor employed at the exhibition runs at 700 revolutions; hence the speed must be reduced in the ratio of 56·1. This is accomplished by a combination of belt and spur gearing. The dynamo shaft is fitted with a pulley 16½in. diameter, driving by means of a short belt on to a pulley 54in. diameter. In order to increase the grip of the small driving pulley on the belt Messrs. Mather and Platt's system of a loose "jockey" pulley is employed. The jockey pulley runs on a stud fixed on an arm projecting from the dynamo bed, and bears against the slack side of the belt. By an arrangement of worm and wheel the arm can be raised or lowered, moving the loose pulley with it, and consequently increasing or diminishing the angle at which the belt is bent over it. By this means the surface of contact between the belt and the driving pulley can be increased, and the slack of the belt taken up, thus at the same time giving an adhesion equal to that of a long belt, and providing means for taking up the slack as the belt stretches. The speed is further diminished by a train of two internal spur wheels and pinions. The combination gives a most effective drive, perfectly noiseless, occupying no more space than the gear for reducing the speed of a steam engine, and under perfect control.

The printing machine is of Messrs. Mather and Platt's latest design for printing cloth up to 34in. wide, with from one to ten colours simultaneously, at a speed of 30 yards per minute. The machine is fitted with transverse motion for the doctors, long rollers, and steam drying. To work it at full speed from 15 to 20 horse-power is required. In order to set the pattern it is essential that the speed of the machine should be so under control that it can be made to "creep" round, and can be stopped in a fraction of a revolution, so as to enable the printer to see that the rollers, each printing one colour, are properly adjusted relatively to one another. With a steam engine this is effected by a throttle valve on the steam inlet, the valve spindle being fixed conveniently accessible to the printing. But a steam engine must have a fly-wheel, and the valves cannot be instantaneously closed, so that the machine cannot be stopped as quickly as might be desired. A dynamo motor, on the other hand, having no dead points, requires no fly-wheel, and the current can be instantaneously shut off, and consequently the machine brought to a stand more rapidly than is possible with steam engine driving. The speed is regulated by a switch-board placed at one side of the machine at the printer's right hand, arranged to insert resistance in the circuit, and so lowering the speed of the motor to any desired extent. The whole floor space covered by the motor, driving gear, and resistance, is somewhat less than that which a steam engine would take, a point of much importance in print works.

The current is conveyed to the motor from a generating dynamo by an insulated copper cable carried under the floor of the Exhibition buildings. The generating dynamo is fixed in the dynamo house immediately adjacent to Messrs. Mather and Platt's pair of vertical engines and dynamos for lighting the fine art section. The distance from generator to motor is forty-five yards, but this might be greatly increased with very slight increase in the proportion of power lost in transmissions. The generating dynamo is also of the Manchester type, and is a similar machine to the motor, capable of generating 25 to 30 electrical horse-power at a speed of 950 revolutions per minute. It is driven by a double-cylinder diagonal engine with cylinders 8in. diameter, 10in. stroke, and running at 180 revolutions per minute, with a short belt driving on the same principle as that used with the motor. Although a separate engine and generating dynamo are provided this is not necessary, and the current could be obtained from any dynamo of sufficient power used for lighting or for working other motors.

Arrangements have been made for connecting the motor cables to any of the four dynamos working the incandescent lamps in the art galleries.

The whole loss in conversion from mechanical to electrical power in transmitting the electrical power and reconverting into mechanical power does not exceed 25 per cent. This is far more than compensated for by the fact that the engine driving the generating dynamo can be worked under the most economical conditions, which is impossible with an engine driving direct.

No better illustration of this could be afforded than the fact that actually a smaller engine is employed for driving the generating dynamo than would have been employed had the printing machine been driven direct.

In a large print works, where there are a considerable number of independent machines, the advantage will be still more conspicuous. For in place of a separate small engine to each machine, working necessarily with low steam pressure, often with considerable back pressure, and generating under conditions where high efficiency is impossible, a single high-class engine can be used working under the most favourable conditions with high pressure steam, high expansion proper automatic cut-off valves giving the highest efficiency. This engine would be employed to drive one or more generating dynamos, which might also be employed for lighting purposes, and from these cables would be taken to each independent machine worked by its own motor.

Such a system has, moreover, the advantage of avoiding the necessity of steam and exhaust pipes and drain pipes for the engines running throughout the building—a point of considerable importance when the operations carried on require great cleanliness.

Briefly, the advantages of the system of electrical motors for the distribution of power may be summarised:—1. Greater economy in consumption of fuel. 2. More perfect control over each individual machine. 3. Greater cleanliness. 4. The availability of the plant used for the distribution of power for electric lighting and other purposes.

ELECTRICITY ON THE "DOGALI."

The Italian cruiser "Dogali," at present the fastest sea-going war vessel in the world, which has been built and armed by Messrs. Sir W. G. Armstrong, Mitchell and Co., of Elswick, has been fitted by her builders with a very complete electric light installation. In all some 150 16 candle-power Swan incandescent lamps are employed for the internal lighting of the vessel, and there are also two search light projectors, supplied by Messrs. R. E. Crompton and Co., of Chelmsford, each taking 125 amperes, with an E.M.F. at the dynamo of 80 volts, and giving a light of about 25,000 candle-power.

The electric engine room, which is situated over the main engine rooms, contains three Parsons electric generators, supplied by Messrs. Clarke, Chapman, Parsons and Co., of Gateshead-on-Tyne. Each generator consists of a Parsons patent steam turbine, driving a direct shunt-wound Parsons dynamo machine, the two being on a single bed plate, and supplies a maximum current of 125 amperes

Digitized by Google

with an E.M.F. of 80 volts. The generators run at the very high speed of 9,000 revolutions per minute (150 per second), but, notwithstanding this, there is no undue beating of the bearings, and as there are no reciprocating parts, and everything is absolutely balanced, there is very little wear and little or nothing to get out of order. Since the lubrication is forced and entirely automatic, the oil circulating continuously through the bearings, the generators will run without attention for long intervals.

As mentioned above, the dynamos are shunt-wound, but each is fitted with an electro-pneumatic governor, which controls the speed of the engine so as to maintain a perfectly constant E.M.F. The total weight of each complete generator, including engine, dynamo, governor, bed-plate, &c., is only 8cwt., and the over-all dimensions are 6ft. 3in. long, 2ft. 3in. high, and 12in. wide, this extraordinarily small weight and bulk in relation to power (10,000 watts), being, of course, largely due to the high speed attained. One of the generators is capable of running all the incandescent lamps used for the internal illumination of the vessel, while the other two are employed to work the two search lights, each of which is supplied with current through a wire resistance of ·2 ohm in order to ensure steadiness in the arc.

By means of a switch-board in the electric engine room any one dynamo can be connected to any combination of one or more circuits; but while this is effected the dynamos are always quite distinct from one another, it being impossible for there to be any connection between them through either the positive or negative conductors. Thus any mishap to the insulation of one dynamo or circuit cannot in any way affect the others. The switch-board was specially designed to meet these requirements by Mr. A. A. Campbell Swinton, until recently electrical engineer to Messrs. Sir W. G. Armstrong, Mitchell and Co., under whose superintendence the whole of the installation has been carried out.

The vessel is also fitted with electrical arrangements for firing the guns from the conning tower or the bridge, it being possible to fire the guns either one at a time or in a simultaneous volley. There is also electrical communication between the torpedo director stations on the upper deck and the discharging tubes beneath, so that the officer at the director can launch a torpedo with his own hand, though he is some distance removed from the discharging mechanism.

Both for the electric light and firing circuits the ship is wired upon the system introduced for ship lighting by Mr. Swinton, according to which the usual wood casing is dispensed with altogether, all the wires being lead sheathed and the joints covered and rendered watertight by means of cast lead boxes filled in with cement. This arrangement has a very neat appearance in the cabins, engine rooms, and other portions of the vessel, as the wires can readily be bent to suit the exigencies of their position, and when painted are scarcely noticeable.

The "Dogali" is the fourth large vessel which Messrs. Armstrong have wired on this system, and there are four other cruisers besides a torpedo boat in progress.

The lead sheathed wire and cable has been supplied by the India-rubber Company, Silvertown.

MODES OF MEASURING THE CO-EFFICIENTS OF SELF AND MUTUAL INDUCTION.*

By Profs. W. E. Ayrton, F.R.S. and John Perry, F.R.S., Members.

(*Concluded from page 60.*)

Capacity.

By following the train of reasoning given in this paper it is easy to show that if, instead of placing a coil with self-induction in one of the arms of the bridge, the arm be shunted with a condenser there will be an apparent diminution of the resistance of that arm, since a resistance shunted with a condenser acts like a *negative* self-induction, and that *this apparent diminution divided by the product of the square of the actual resistance of the arm into the reading of the scale of the secohmmeter corresponding with the speed at which balance is obtained gives the capacity of the condenser absolutely in farads.* This formula is far simpler than the one given by Clerk-Maxwell for the capacity of a condenser determined by placing the condenser on one of the arms of the bridge and rapidly alternating the connections of the condenser with the bridge.

APPENDIX I.

Other Methods of Measuring a Coefficient of Self-Induction.

As mentioned in the early part of this paper, a number of *cumulative* methods were tried by Mr. Sumpner for measuring self-induction, and the appropriate formulæ worked out by him in each case. The following short account of them is given as evidence of our desire not to publish the secohmmeter method until we had satisfied ourselves that there was not a better one. Indeed, that is one of the reasons why the publication has been delayed so long after the instrument has been in practical use.

* Paper read before the Society of Telegraph-Engineers and Electricians on April 28th, 1887.

Connect the coil of resistance, r ohms, and a coefficient of self-induction, L secohms, with the terminals of a condenser of F farads capacity, Fig. 8. By means of a reversing communicator, C, alternate the connections of the coil and condenser at the rate of N times per minute with the terminals of the circuit consisting of the battery of E.M.F. equals E volts and a galvanometer, the resistance of which, together with that of the battery is g ohms. The object of using the condenser is to prevent the self-induction of the coil producing sparks on reversing.

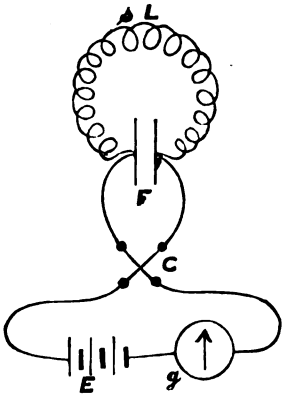


Fig. 8.

Let D_0 be the galvanometer deflection when the commutator is at rest, and D_1 when it is revolving, then it can be shown that

$$L = F s^2 + \frac{g+s}{2} \cdot \frac{D_0 - D_1}{N D_0} \text{ secohms},$$

if the reversals of currents in the coil be not too rapid for the currents to reach their steady value, and if the reversing commutator reverses instantaneously without short-circuiting. But the method, as it stands, seems impracticable, as it is impossible to devise a commutator that will reverse without short-circuiting or producing a discontinuity for a certain time between every reversal.

If there be short-circuiting, then the condenser may be dispensed with, and if the time of short-circuiting be small compared with $\frac{L}{s}$, and if g be not small compared with s, it can be shown that

$$L = \frac{g+s}{2N}\left(\frac{D_0 - D_1}{D_0} + m\right),$$

where m is a very small constant depending on the values of g and r and on the proportion of periodic time of commutation during which the short circuit lasts. m may be eliminated by taking two readings, D_1 and D_2 at different speeds, N_1 and N_2, and if the E.M.F. used when the commutator be revolving be n times as great as when the commutator is at rest, we have

$$L = \frac{g+s}{2D_0} \cdot \frac{D_2 - D_1}{N_2 - N_1} \frac{1}{n}.$$

This method of testing, although fairly simple, and possessing the great advantage of making the effects *cumulative*, is not nearly as sensitive as the following *zero cumulative* method, which is based on the same principle.

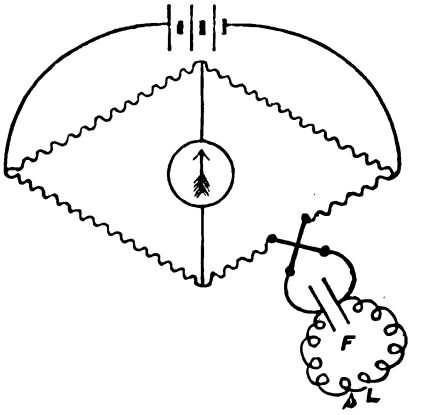

Fig. 9.

The coil with self-induction condenser and commutator are put in one of the arms of a Wheatstone bridge, as shown on Fig. 9, then with the same notation as before it can be shown if

(1st) The speed of reversal be not too great for the currents to reach the steady value,

(2nd) The commutator reverses instantaneously without short-circuiting,

that $$L = F s^2 + \frac{1}{1 + \frac{\sigma}{r_1}} \cdot \frac{T\sigma}{2},$$

Digitized by Google

where σ is the apparent increase of resistance, r_s the resistance of s plus that of the network between the extremities of s supposing s removed, and T is the time of a reversal.

It is easy to arrange that $\frac{\sigma}{r_s}$ shall be negligible, and, unless F or s be large, Fs^2 can also be neglected, so that we obtain the very simple formula

$$L=\frac{T\sigma}{2},$$

a result that is independent of λ, the coefficient of self-induction of the galvanometer.

To satisfy condition 2 is extremely difficult, if not impossible, and therefore it is better to allow the commutator to introduce a short circuit between the reversals, in which case the condenser previously employed to prevent sparking at the reversals may be dispensed with.

As the complete investigations previously made on the use of the secohmmeter for the measurement of the coefficients of self and mutual induction have shown that self-induction of the galvanometer does not seriously affect the practical result, we will, for simplicity, in this investigation of the theory of the zero short-circuiting commutator test, neglect the self-induction of the galvanometer from the beginning. Consequently the current x through the galvanometer (Fig. 9) is given by the equation

$$A\,x+B'L\frac{dx}{dt}=Ep\sigma.$$

Now, if Q_1 be the quantity of electricity that flows through the galvanometer during the reversal, excluding the period when the commutator is short-circuited, and Q_2 the quantity that flows through during this period, and if T and τ be the times of a complete reversal and of a short circuit respectively, reckoned from the commencement of the short-circuiting,

$$A\,Q_1+B'L\left(x_T-x_\tau\right)=Eps\,(T-\tau);$$

also

$$Q_2=\frac{Ep(s+\sigma)}{A'}\tau,$$

where A' is the value of A when s is made equal to nought. If the time of short-circuiting be but a small portion of the whole time of a reversal, Q_2 will be but a small correction. And an examination of the value of A, given on page 19, will show that unless s be very large compared with $b+r$ or with $g+q$, putting s equal to nought will not much change the value of A; in other words, A' may be taken as equal to A. Hence we have

$$A\,(Q_1+Q_2)+B'L\left(x_T-x_\tau\right)=Ep\,(\sigma T+s\tau).$$

Now Q_1+Q_2 must equal nought for balance, and $\frac{\tau}{T}$ is a constant, l say for a given adjustment of a given commutator. Hence

$$B'L\left(x_\tau-x_T\right)=-EpT(\sigma+ls)\quad\ldots\quad(18)$$

If y_s be the *steady* value of the current in s, then taking into account the partial dying away of the current during the time of short circuit, τ, the current in s immediately after reversal will be

$$-y_s\,\epsilon^{-\frac{s\tau}{L}},$$

and if τ be small compared with $\frac{s}{L}$, this is equal to

$$-y\left(1-\frac{s}{L}\tau\right).$$

From equations (6) and (7), given above, we can deduce that

$$B'x+Ep=B''y,$$

where B' or B'' are functions of the resistances; therefore

$$\frac{B'x}{\tau}+Ep=-B''y_s\left(1-\frac{s}{L}\tau\right)$$

$$B'x_T+Ep=B''y_s$$

$$\therefore B'\left(x_\tau-x_T\right)=B''y_s\left(\frac{s}{L}\tau-2\right)$$

$$=\left(B'x_T+Ep\right)\left(\frac{s}{L}\tau-2\right);$$

and we have seen that

$$B'=\frac{A}{r_s},$$

and

$$x_T=\frac{Ep\sigma}{A}$$

$$\therefore B'\left(x_\tau-x_T\right)=\left(1+\frac{\sigma}{r_s}\right)\left(\frac{s}{L}\tau-2\right)$$

Consequently, substituting in equation (18), we have

$$2L\left(1+\frac{\sigma}{r_s}\right)\left(1-\frac{s}{2L}\tau\right)=T(\sigma+l$$

Now $\frac{\sigma}{r_s}$ will probably be negligible and $s\tau=slT$,

therefore we have

$$L=\frac{T}{2}(\sigma+2ls);$$

hence the effect of the short-circuiting is to diminish the value of σ by $2ls$.

Let two observations at speeds of rotation N_1 and N_2 revolutions per minute be made, giving apparent increases of resistance σ_1 and σ_2, then, since

$$T_1=\frac{60}{2N},\quad\text{and}\quad T_2=\frac{60}{2N_2},$$

we have

$$L=15\,\frac{\sigma_2-\sigma_1}{N_2-N_1}.$$

The following is a sample of the results obtained by using this method with the solenoid previously employed, of which the resistance is about 4 ohms, and the coefficient of self-induction 0·0215 secohm.

N	$s+\sigma$
0	4·13
850	5·20
1030	5·50
1230	5·80
1490	6·20
1650	6·40
1610	6·35
1100	5·57
980	5·4
890	5·3
710	5·0

Plotting these results on squared paper, and determining the value of $\frac{\sigma_2-\sigma_1}{N_2-N_1}$ from the mean slope of the line L was found to be about 0·0216, a result very near the truth. Subsequent experiments, however, did not give nearly as accurate results, possibly on account of some unknown resistance in the commutator, and that leads to one reason why the method is much inferior to the use of the secohmmeter, in that the commutator is in one of the arms of the bridge, so that any unknown variation of the resistance of the contacts introduces an error into the test, which, as already explained, cannot happen with the secohmmeter, as neither of the commutators is in any one of the four arms of the bridge. This method, therefore, is distinctly inferior to the use of the secohmmeter.

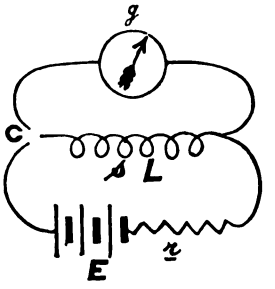

FIG. 10.

Fig. 10 shows another plan tried by Mr. Sumpner, which is cumulative, and although not a zero method, the deflection of the galvanometer from zero is entirely due to the effects of self-induction the coefficient of which is to be measured; the method, therefore, is fairly sensitive, although inferior, of course, to a zero method. By means of the commutator, C, the coil of resistance, s, ohms, and coefficient of self-induction, L, is put first in circuit with a battery of E.M.F. equal to E volts, which may be unknown, and a resistance the value of which together with that of the battery is r ohms, and next with a galvanometer of resistance g ohms; the alternation being produced N times per minute, a speed which must not be too great to prevent the current reaching its steady value each time that the coil is connected with the battery, and to die away in the coil each time that it is connected with the galvanometer. Let D_0 be the galvanometer deflection when the battery and resistance are connected directly in series with the galvanometer, so that

$$D_0=\frac{E}{b+g},$$

and let D_1 be the mean deflection obtained with the commutator working then

$$D_1=\frac{N}{60}\cdot\frac{L}{s+g}\cdot\frac{E}{b+s};$$

$\therefore$ eliminating E, we have

$$L=\frac{60}{N}\cdot\frac{(s+g)(s+b)}{b+g}\cdot\frac{D_1}{D_0}$$

To prevent sparking it would be necessary to connect the coil with the galvanometer for a short time before disconnecting it from the battery, and a small correction would have to be applied, depending on the time that the coil was connected with both galvanometer and the battery. This correction takes the form given by the formula

$$L=\frac{60}{N}\cdot\frac{(s+g)(s+b)}{b+g}\cdot\frac{D_1+l\,m\,D_0}{D_0},$$

where l is the ratio of the time of a short circuit to the time of an alter

Digitized by Google

nation, and m is a numerical function of the resistances, such that when b is nought m is equal to $\frac{s}{g}$.

By taking two readings, D_1 and D_2, at speeds N_1 and N_2, we eliminate n and obtain

$$L = \frac{60}{n D_0} \cdot \frac{(s+g)(s+b)}{b+g} \cdot \frac{D_1 - D_2}{N_1 - N_2},$$

where n is the ratio of the E.M.F. used when the commutator is revolving to that used when it is at rest.

This method is suitable for employment in cases where only very small direct currents can be employed, as, for instance, in testing the coefficient of self-induction of a high-resistance Thomson galvanometer without removing the needles. But far greater sensibility is obtained by using the method previously described, in which the coil with self-induction is rapidly reversed, since with that method far stronger currents can be sent through the galvanometer, as the effect of rapidly commutating the terminals of the galvanometer the coefficient of self-induction of which is to be measured is to send alternating currents through it. These alternating currents do produce a deflection, but the deflection is but small, so that the strength of the current that can be employed is only limited by the gauge of the wire wound on the galvanometer that is being tested.

APPENDIX II.

Non-Zero Use of the Secohmmeter.

I. In what has preceded we have supposed that the secohmmeter was turned at such a speed, and the resistance of the arms of the bridge so adjusted that the galvanometer needle was brought to the zero it would stand at if no current whatever were passing through the galvanometer. But that is not necessary, for equation (13) may be written in the form

$$Q_1 = E \frac{(qr - ps)\left(T - \frac{B}{A}\right) - p\left(L + \frac{p+r}{p}M\right)}{A},$$

where p, q, and r are any resistances in the arms of the bridge (Fig. 7, page 59), and s the resistance of the coil under test. Also

$$Q_2 = E \frac{(qr - ps)}{A} \cdot \frac{\lambda}{g},$$

therefore generally the current that will pass through the galvanometer when the secohmmeter is turning at n revolutions per second is

$$n(Q_1 + Q_2) = \frac{nE}{A}\left\{(qr - ps)\left(T + \frac{\lambda}{g} - \frac{B}{A}\right) - p\left(L + \frac{p+r}{p}M\right)\right\} \quad (19)$$

producing a deflection, d, say.

If the secohmmeter be stopped and steady currents employed let balance be obtained by increasing s to $s + \sigma_1$, the values of p, q, and r remaining as before, and let a deflection d' be produced when σ_1 is changed to σ_2, so that d' is the deflection produced by a current

$$\frac{Ep(\sigma_1 - \sigma_2)}{A}.$$

Hence, since $$qr - ps = p\sigma_1,$$

we obtain from (19)

$$\frac{d}{d'} = \frac{n\left\{\sigma_1\left(T + \frac{\lambda}{g} - \frac{B}{A}\right) - \left(L + \frac{p+r}{p}M\right)\right\}}{\sigma_1 - \sigma_2} \quad \ldots (20)$$

Let $$d = l\,d',$$

where l is the lead of the secohmmeter, then we have from (20)

$$L + \frac{p+r}{p}M = \frac{l}{n}\sigma_2 \text{ approximately} \quad \ldots (21)$$

Now σ_2 may be regarded as the apparent increase of resistance of the coil produced by the self-induction on turning the secohmmeter at the rate of n revolutions per second when the zero used in measuring the resistance with steady currents is at a distance d' from the true zero, and the zero used in obtaining balance with the secohmmeter revolving is at a distance $l\,d'$ from the true zero. This leads us to the following *simplified* method of measuring L the coefficient of self-induction, or $L + \frac{p+r}{p}M$ if there be also mutual induction, without its being necessary to *accurately* measure the true resistance of the coil at all.

1. Let a *rough* approximation be made to the resistance of the coil, using steady currents, and let the resistance of the coil appear to be s ohms when the spot of light is somewhere near the zero—say at 130 divisions from the zero.

2. Let the secohmmeter rotate at n revolutions per second, and let the coil now have an apparent resistance of $s + \sigma$ ohms when the spot of light is brought, not to zero, but to $l \times 130$ divisions on the scale; then

$$L = \frac{\sigma}{n}$$

or $$L + \frac{p+r}{r}M = \frac{\sigma}{n}$$ if there be also mutual induction.

II. At the commencement of this paper it was mentioned that we originally measured the coefficient of self-induction, not by altering the resistance in one or more of the arms in order to obtain balance, but by leaving the resistances in the arms unaltered, and observing the galvanometer deflection when the secohmmeter was rotated. Equation (19) at once gives the formula that we employed with that method of using the secohmmeter, for if p, q, and r be the resistances of the arms that will produce balance with s for steady currrents, equation (19) becomes

$$n(Q_1 + Q_2) = -\frac{nEp}{A}\left(L + \frac{p+r}{p}M\right);$$

let this current $n(Q_1 + Q_2)$ produce a deflection d_1. Next let s be increased by a known resistance s', and let the galvanometer deflection for steady currents in the arms be d_2, then this deflection is produced by a current

$$-\frac{Eps'}{A}$$

$$\therefore \frac{d_1}{d_2} = \frac{n}{s'}\left(L + \frac{p+r}{p}M\right)$$

or $$L + \frac{p+r}{p}M = \frac{d_1}{d_2} \cdot \frac{s'}{n}$$

or $$L = \frac{d_1}{d_2} \cdot \frac{s'}{n}$$ if there be no mutual induction,

the formula originally employed for measuring L.

This comparative deflection method of using the secohmmeter has received a high testimonial for great sensibility from MM. P. Ledeboer and G. Maneuvrier, who, unaware of the fact that it was devised and used by us rather more than a year ago, have recently brought it to notice in France. The large amount of excellent work that M. Ledeboer has done on self and mutual induction makes him well competent to judge of the relative sensibility of methods of measuring the coefficients; therefore we feel sure that he and his colleague will be the first to recognise the great increase of sensibility of our *zero cumulative* method beyond even the sensibility possessed by our *amperative deflection cumulative* method for measuring the coefficients of self and mutual induction.

Use of Secohmmeter without Speed Indicator.

III. It is important to notice that *all* known zero galvanometric methods of comparing the coefficients of self or mutual reduction with one another, or with the capacity of a condenser, can be increased *enormously* in sensibility by the use of the secohmmeter, and since in such cases the speed of rotation need not be known, a very simple form of secohmmeter without speed indicator can be employed. The comparison of the coefficients of self or mutual induction with one another, or with the capacity of a condenser, is usually effected by tests that are completed during the growth or the dying away of a current, since it is during the variation of a current that self or mutual induction, or the electrostatic capacity of a condenser evidence themselves. The effect of an error in the balance only lasts for a very short time, and therefore is very small if the error be small—that is, the tests are not sensitive. Resistances are compared with steady currents lasting for a considerable time, but before attempting to accurately measure an unknown resistance it is a common practice to give the bridge key a tap to see whether the balance is so far out that a deflection of the galvanometer is produced for a current lasting for a very short time. Such a preliminary test is intentionally very unsensitive, but its sensibility is equal to that of the ordinary tests made for comparing the coefficients of self and mutual induction. But by the use of the secohmmeter it is now possible, not merely to measure the coefficient of self and mutual induction and the capacities of condensers *absolutely*, but, in addition, *to secure the same high degree of sensibility with tests that have hitherto had to be completed during the growth and dying away of a current that it is customary to obtain in the use of the Wheatstone bridge for measuring resistances with steady currents.*

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the meeting of this Society at the Institution of Civil Engineers on Thursday, 26th May, Dr. Hopkinson in the chair, the Secretary read a paper by Mr. C. T. Fleetwood on "Underground Telegraphs."

After referring to his previous paper on this subject in 1875, Mr. Fleetwood thought that some account of the results of the work then carried out would now be acceptable to the Society First, however, he would remark that although we take a great deal of credit for our system of insulated underground telegraph system, the real originator was Mr., afterwards Sir, Francis Rolands, who, in his garden at Hammersmith, as long ago as 1816, demonstrated the practicability of the idea; and who, in his book dated 1823, described by anticipation the methods that would probably be employed in future work of that kind. His trough of wood, 525ft. long and 4ft. deep, with buried glass tubes, into which copper wires were drawn, may be regarded as the germ of the present underground telegraphs. Moreover, he suggested the laying of wires along the high road, with testing points at convenient intervals, and men stationed there to look after faults. He clearly saw the commercial value of the telegraph long before it became a practical reality; and some portion of his cable, now the property of Mr. Latimer Clark, and which was there for inspection, would be found to be in as good condition as any we could produce nowadays. Coming to the period of 1837, when Cook and Wheatstone took out their first patents, the year from which we date the Jubilee of the Telegraph, their scheme included an underground telegraph; and five wires were thus carried in grooved wooden troughs, and covered with pitch, from Euston-square to Camden-road, a specimen of which was now on view. In the following year an iron tube was employed for enclosing the wires on the Great Western Railway between Paddington and West Drayton. India rubber and tape were also used on this occasion. For overhead wires the first poles were erected from Nine Elms to Gosport, part of the way through London in lead tubes of 50 yards sections, and

Digitized by Google

the wires served with tar and grease. Portions of this were recently recovered, and were found after an interval of 40 years to be well insulated and the tar perfectly fresh. Nevertheless, the wires on the whole were frequently faulty, and the wonder was that communication over any long distances could be maintained at all. The remedy came in the discovery of gutta percha, an effectual insulator; and between 1842-5 some of this material was employed for that purpose. Not however, till 1847 was any patent taken out for its use specifically as a dielectric, and for a considerable time, although the material was purer and far better than we can get it now, the manufacture and manner of covering the wires were very imperfect. The Electric Telegraph Company, on the occasion of their transferring their headquarters from the Strand office to the new office in Lothbury, served their wires with cotton covering, and drew them into iron tubes; and soon after connected them with several of the principal railway stations in the same way. It was in 1849 that the first gutta percha covered wire was introduced between the city and Shoreditch station. From that time the employment of gutta percha covered wires rapidly increased, and by the year 1854 the company just mentioned owned 350 miles of such wires. In 1850 the Submarine Telegraph Company had laid down similar wires to Dover in connection with their cable to France, and in 1853 which was a very busy year for the telegraph of this country, underground wires were carried along the London and North-Western Railroad from London to Manchester by the Electric (now the Electric and International) Telegraph Company, and a number of lines were also established by the British Company, which had started in competition with the Electric, chiefly along the main roads, whilst the Magnetic, another competing company, started wires to Liverpool, as well as in Cork and Queenstown. These two companies soon combined and worked in opposition to the old company. Mr. FLEETWOOD here described the general methods of laying down these wires. In some instances the gutta percha was their only covering; in others they were served also with tarred tape. The outer tubing for some portion of these lines was of earthenware instead of iron. These were completed in 1855, but a few years after were condemned and put up on poles. Their failure was attributed to the gutta percha covering, and the material was sold for less than a third of what it had cost. Portions of it, however, were left; and on its recovery recently such of it as had been served with tarred taping is found to be in splendid condition, though not when enclosed in wooden troughs, except where the position was particularly favourable. Nor was the split iron pipe of that period much better than wood. Solid iron pipes are now invariably used and the wires drawn in. The danger from inroads of gas to split pipes is very great; and as regards earthenware, being jointed with clay, tree roots often found their way into such tubes, and completely destroyed the work. It may be said of the work of that period generally that it was too hurriedly done, the men were ignorant and inexperienced, and the supervision was not as well informed or as careful as now. The United Kingdom Company—a later enterprise—for example, made the mistake of using split pipes under the footway, and were soon broken down in consequence. Coming to the year of the transfer of the telegraphs to the Post Office in 1870, the necessity for recovering and increasing the number of underground wires enabled us to discover many faults and the causes of them; and in 1874, on the removal from Telegraph-street to the new Post Office premises in St. Martin's-le-Grand, advantage was taken of the lessons thus learned. There was at that time an outcry against overhouse wires, though the telephone had not yet been invented, and the occasion was seized to lay all the Post Office wires underground by the most approved methods. Then came the telephone and with it the necessity for cabling large numbers of fine twisted wires in comparatively small pipes The plan of Mr. David Brooks for insulating wires by means of liquid oil was here described, thirty or forty of them being insulated in that way in pipes between Waterloo and Clapham Junction Stations. The experiment has answered well and deserved to be tried on a larger scale, provided the leakage of oil, which has been considerable, can be obviated. At present the Post Office possesses in the metropolis about 240 miles of tubes containing 12,000 miles of wire, or an average of 50 wires for each tube, and these are continually being taken out and increased, the flush boxes which occur at every 50 yards or thereabouts serving admirably for this purpose, without the necessity for ever breaking down the circuits. For simplicity, efficiency and durability, Mr. FLEETWOOD, after many years' experience, considered that the system of gutta percha covered wires in iron tubes, such as he had described, could not be surpassed.

A number of specimens of cables of various ages, some of them of great historical interest, were exhibited in illustration of Mr. Fleetwood's paper.

Colonel WEBBER suggested that the cause of deterioration of modern gutta percha wire was due to adulteration. Some he had inspected which was laid down at Lowestoft twenty years ago was still as good as new. None such is obtainable now; and this fact accounts for the discreditable character of much of our modern work. He laid stress on the importance of completing that system which, in his recollection, was inaugurated by Mr. Culley, and carried out by Mr. Shipp—a system which enables us to renew, repair, or enlarge at pleasure without interrupting the electrical continuity. Colonel Webber then made an earnest appeal to capitalists who are interested in telephonic extension, that they will exercise some ordinary foresight in respect to their present overhouse telephone wires. It is obvious that these wires cannot be allowed to go on indefinitely increasing; and it is high time that some plan be started to meet the requirements of, say, ten years hence. The interval between now and the expiry of their patents, and the period when the public will endure the net work of overhead wires no longer, should be utilised by laying aside capital, and by carefully and cautiously establishing conduits wherein these wires may some day all be securely buried out of sight.

Mr. A. J. S. ADAMS questioned Mr. Fleetwood as to the durability of the underground work completed in 1875, and generally defended overhead wires.

Mr. W. H. PREECE stated with reference to the wires in earthenware tubes between Liverpool and Manchester, that the wires would apparently last for ever, but that the tubes had had to be replaced by iron ones, for reasons mentioned by Mr. Fleetwood. Referring to the historical portion of Mr. Fleetwood's paper, Mr. Preece expressed the opinion that Roland's paper in 1823 would do credit to any electrical engineer to-day, such was his insight and almost prophetic instinct with regard to the then remote future of the electric telegraph. Hardly less to be complimented in the practical branch of the subject was Mr. C. F. Varley, whose wonderful method of testing with his differential galvanometer rendered the employment of underground wires permanently available by discovering their faults without digging up the wires. He concurred in the view that gutta percha had greatly deteriorated; but, in spite of that fact, nothing better had been used as yet for outdoor work. But while the dielectric had gone down in quality the wire had decidedly gone up, the copper now being introduced giving immensely better results in telegraphy and telephony than any formerly obtained on either copper or iron. Brooks' system of insulation had not failed, but it could not be described as very successful. On the other hand, some results of bituminous covering were very remarkable, as shown that night; and an invention lately brought over to this country from America by Mr. Eddison was highly promising. It consisted of a dielectric of resin oil and resin, a dry compound, covered with lead. The tests gave 19,000 megs. per mile when the specimens were first brought over, and on re-testing lately their condition remained unchanged. On the question of underground wires for the trunk lines, although there were electrical as well as financial objections to their adoption, some good grounds existed for the establishment of a certain number of such lines to important centres throughout the country; and if Parliament would only sanction the expenditure of the two-and-half millions necessary for the operation, the present Postmaster-General was anxious to have it done; and possibly such an invention as that introduced by Mr. Eddison might greatly reduce the commercial as well as electrical drawbacks to the scheme. Even now we have more underground wires—25,000 miles—than any other European country.

Mr. ALEXANDER SIEMENS made mention of the early attention given to gutta percha by Dr. Werner Siemens, and of the fact that the compound with which the submarine cables recently laid by Siemens Brothers had enabled those cables to be duplexed, which could not be done with other cables.

After a few observations from Mr. EDDISON and Mr. BELL, Mr. FLEETWOOD briefly replied, chiefly in regard to wires laid down since 1870, which he said showed no signs of decay, except where they had been chafed by careless drawing through the iron tubes without a serving of tape.

A short paper on "Driving a Dynamo with a Very Short Belt," by Profs. AYRTON and PERRY, was then read by the first-named gentleman.

PHYSICAL SOCIETY.—May 28.

Prof. W. E. AYRTON, Vice-President, in the chair.

Dr. S. P. THOMPSON read a note on *Transformers for Electric Distribution.*

In the simple algebraic treatment of the dynamo several assumptions approximately true for well-made machines are made use of. The author finds that a similar set of assumptions for transformers greatly simplifies the algebraic theory.

1st. The iron, copper, and insulation are assumed good. 2nd. The reaction of the secondary on the primary (other than that desired) is small. Thus, if the primary be supposed to be supplied with constant mean current or constant mean potential difference, this is not to be altered by the current in the secondary. 3rd. No magnetic leakage; so that the coefficient of mutual induction is the geometric mean between their coefficients of self-induction. 4th. The quantity of copper in the primary and secondary are to be equal. These assumptions are shown to be legitimate, and the ratios of resistances, E.M.F.'s, currents, and coefficients of self-inductions are expressed in terms of the ratio of the numbers of convolution, which ratio is represented by $p = \frac{S_1}{S_2}$. From analogy with the dynamo it is shown that $E_2 = \frac{\omega M E_1}{\sqrt{R_1^2 + \omega^2 L_1^2}}$, where $\omega = 2\pi n$, E_1 and E_2 the E.M.F.'s of the primary and secondary respectively, and R_1 and L_1 the resistance and self-induction of the primary coil. If R_1 be neglible, the above reduces to $E_2 = \frac{\omega M}{\sqrt{\omega^2 L_1^2}} E^1 = \frac{E_1}{p}$ since $\frac{L_1}{L^2} = p^2$, and $M = \sqrt{L_1 L_2}$.

The latter part of the paper contains a general investigation of two neighbouring circuits, both having self-induction, and it is shown that the effective resistance of the primary is increased and the self-induction decreased by closing the secondary circuit.

Mr. KAPP said the investigations assumed the coefficient of induction to be constants, and that the phases of current in primary and secondary were opposite. The former being by no means true, he asked what values were to be taken; and he believed the phases of current are not opposite in ordinary transformers.

Mr. SWINBURNE protested against the use of formula to calculate the inductions when the required data could be obtained much more accurately from Dr. Hopkinson's curves on magnetisation of iron. He also thought the curve of sines did not nearly represent the current curve for ordinary machines.

Mr. BOSANQUET thought the effective magnetisation of a transformer

Digitized by Google

would be different to that of a dynamo, for in the former permanent magnetism was not utilised.

In reply to Mr. Kapp and Mr. Swinburne, the AUTHOR pointed out that as the coefficients of induction enter in both numerator and denominator, it would not matter which set of values were taken if the resistance was small compared with ω L; and that self-induction tends to smooth out irregularities in the current curve. Prof. AYRTON described a method of regulating a series transformer devised by himself and colleague some two years ago, based on analogy with a compound dynamo. Referring to the variation of L with current, he sketched a curve connecting them, obtained by Mr. Sumpner at the Central Institution, and mentioned that the E.M.F. curve of a Ferranti dynamo is an exact sine curve. He believed problems involving alternating currents would be greatly simplified by using a new set of measurable quantities, such as would render the equations as simple as possible. At Prof. Thompson's request Prof. Ayrton exhibited a lecture experiment illustrating the action of transformers. The secondarys of two ordinary induction coils were joined in series through long fine wires, and an incandescent lamp placed in the primary circuit of one lighted up on completing the primary of the other coil, in which a battery was placed.

On Magnetic Torsion of Iron Wires, by SHELFORD BIDWELL. This is an account of experiments made on the twisting produced by sending a current along magnetised iron wires, and the author shows that Wiedemann's explanation of these phenomena (by assuming a difference in molecular friction at the polar and lateral surfaces of magnetised molecules) is unsatisfactory. The wires were magnetised longitudinally by means of a solenoid, in the axis of which the wires were suspended. To obtain consistent results it was found necessary to demagnetise the wire between the observations. This is done by several currents of gradually decreasing strength, and a simple arrangement of rheostat and commutator devised for this purpose was exhibited.

Two sets of experiments were made, in which the current in wire or solenoid was kept constant, whilst that in the other was varied. The amount of twisting does not increase continuously when the currents are increased, but attains a maximum when the inclination of the helix, representing the director of magnetisation, is inclined at about 33deg. to the axis of the wire. When the current in the solenoid was kept constant, and that in the wire increased, a permanent deflection remained on stopping the current. For small currents in the wire this deflection was diminished on starting the current, whilst stronger currents increased the deflection. For some intermediate value of the currents no change took place, and this value was dependent on the current in the solenoid. Experiments were shown illustrating these phenomena.

COMPANIES' MEETINGS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The sixth annual general meeting of the shareholders in this Company was held at the City Terminus Hotel, Cannon-street, yesterday, under the presidency of Mr. C. L. W. FitzGerald.

The SECRETARY (Mr. Chas. Curtoys) read the notice convening the meeting, and the minutes of the last meeting were taken as read and confirmed by the present meeting and signed by the Chairman. The report of the Directors and statement of accounts were also taken as read.

The CHAIRMAN: Gentlemen, on this occasion of my rising to address you I do so with considerable satisfaction, for an event has taken place which has placed us in a position to do something a little out of the common, and that is the amalgamation of the River Plate Telephone and Electric Light Company with the United Telephone Company of the River Plate. You will see that, as a consequence of this amalgamation, the shares held by this Company in the late River Plate Telephone Company have ceased to exist. We have received a large sum owing to us—no less than £10,277—from the River Plate Company, also £1,250 as a compromise of the contract which that Company failed to fulfil for the supply of telephones. Further, the cumulative 9 per cent. dividend, amounting to £1,838, has been paid to us, and an amount standing in our books at the sum of £9,256 has now been converted into £8,985 in shares of the United River Plate Telephone Company (Limited) at par, and £11,554 in cash has also been received. There is also a very considerable sum of money to be received from this amalgamation. Of course it is very difficult to know how much that will amount to; but I think, roughly speaking, I might put it down at somewhere about £8,000, perhaps more. But that depends very much upon how the business in the River Plate is regulated—in other words, upon whether we get a good price or not for the assets that we have over there. Now, gentlemen, this £11,564, having come to us, so to speak, from the sale of the shares which we held in that company we, the Directors, are in this position, that we have got a sum of money which we did not know very well what to do with, and, with the consent of our auditors, we came to the conclusion that it would be much better to hand that money back to the shareholders in the form of 1s. per share, reducing the capital by the like amount, than anything else. I will explain that to you by this. You see we have got against the capital, expenditure, goodwill, patent rights, &c., £87,000. Now, we are going to reduce that at once by £11,564, which of course, to a certain extent, places our business in a better position really, in so far as we shall be able to pay bigger dividends on the smaller amount of capital which we shall have to deal with in the future, the shareholders meanwhile getting the 1s. back into their own pockets. I think, gentleman, that should be very satisfactory to you. I wish just to make one other remark in this connection. There seems to exist in certain shareholders' minds some confusion as to this reduction of capital. They appear to confuse it with the 5s. reduction of capital which was lost during the late management. Now this is, so to speak, a sum of money which we are going to pay absolutely to the shareholders and not to take away from them, and you will at once see that there is a very great difference between the two cases. We propose doing that, and to do it we shall have to call an extraordinary general meeting after this one that we are now holding, and then we shall have to go to the Court to obtain the necessary powers to pay you back that 1s. I am very happy to state that the Board decided that we should exhibit our telephones at the Exhibition at Brussels, and that on all hands, in the Belgian press and elsewhere, it was admitted that our instruments were really first class. The only thing I have got to say about the subject is this, that unfortunately people abroad want things cheap. They do not care for a high-class instrument, and it is a very difficult thing to do to make a cheap instrument which you can really call high class. This fact, however, has led to a considerable number of inquiries from various places, and we hope that some good may arise in the shape of an increased sale of our telephones by having exhibited them at Brussels. You heard at the last meeting that we desired, and we asked your permission, to join the Edison-Gower-Bell Telephone Company in a law suit to prosecute infringers in Belgium. So far we have obtained permission of the Courts to bring our action, which, of course is a great step. We have now got to prove that our patent is the master patent of the telephones which are used in that country. I have no doubt that the trial will take place shortly, but I need not remark to you that everything has been done to try and put obstacles in our way. They have stopped us as much as they possibly could by laying before us the enormous amount of damages which the infringers will sustain for their not being able to use the telephones, and one thing or another; but up to the present time everything has gone satisfactorily for us. That is a source of profit that may possibly some day astonish us. I cannot say it will, but it may. The next point that I have to allude to is that we had certain machinery in the factory which did not belong to us. Now, that was a very unsatisfactory position to be in, because at a moment's notice possibly something might have happened that would have caused the machinery to be taken away, and the opportunity having occurred, we thought that it would be best to buy that machinery at once, which we did, so that it all belongs to the Company now, and we are in as perfect a position for manufacturing purposes as we possibly could be. I think you will approve of that step. I think myself that it was a very wise one indeed to take. The next point I have to draw attention to is that you will see that our subsidiary companies are steadily improving, which I regard as very encouraging, because it leads one to believe that sooner or later those companies will be a great support to us. You will also see that the two remaining companies—the Telephone Company of Austria and the Edison-Gower-Bell Company—have increased by no less than 683 subscribers with an annual rental of £4,402. Gentlemen, it is with very sincere regret that the Board have to announce the death of one of their colleagues. Mr. John Taylor was a man of exceptional ability and of great business capacity, and I am sure he rendered the Company great service. I may tell you that he died absolutely in harness. Major FitzGerald and Mr. Bateman have also retired from the Board to take their seats on the Board of the United River Plate Telephone Company. I think the thanks of the shareholders are due to these gentlemen for their past services. I very much regret that they have to leave us, but they have gone on to the Board of that company to look after our interests. Therefore, I think we ought to be very much obliged to them for resigning their seats. The figures for the year I will now read to you. They show a net profit of £8,957, which with the amount carried forward leaves a balance of £10,127. We are about to propose to you that this shall be dealt with by paying you a further dividend of £2. 10s. per cent., which will make, with the interim dividend in November last, 5 per cent. for the year. We have further written off £558 for depreciation of plant, machinery, and furniture, leaving £1,695 to carry forward. We have kept our stock down. It now stands at the amount of £3,658, and I am also happy to state that though that is principally due to the River Plate Company having paid us the £10,000 odd which they did, the money owed to us is not quite so gigantic as usual, the total amount being £8,144, of which we have reserved £1,487 against any possible non-receipt of moneys. There is one other matter that I should like to allude to. You will see that the Edison-Gower-Bell Telephone Company's 20,000 preference shares of £1 each and the 15,000 ordinary shares of £1 each have been reduced in value—in other words, we have written down that value, roughly speaking, by £4,000, thereby really placing that security on a more satisfactory footing, to be dealt with at some future date. I am happy to say that our United River Plate Company's shares, of which we hold 1,797, are now quoted on the Stock Exchange, and are a marketable security standing at a premium. I think that is cause for congratulation among the shareholders. The Telephone Company of Austria, in which we have £34,000 debentures at par, has paid its interest regularly, and is now in a position to state that it is really earning a dividend of which we shall now reap the benefit. He concluded by inviting the shareholders to ask any questions they might desire.

A SHAREHOLDER asked whether the River Plate Company was going to be a customer of the Consolidated Company.

The CHAIRMAN expressed a hope that that would be so.

Another SHAREHOLDER asked whether the United Telephone Company took all its instruments from this Company, or were the Directors aware of orders having been placed elsewhere.

The CHAIRMAN: I can only say that we think they take all their instruments from us—we have no reason to suppose otherwise.

Digitized by Google

A SHAREHOLDER wished to know whether they had £120,000 invested in Austria.

The CHAIRMAN: No, sir; that you will see is simply a *per contra* item on one side of the account. It is the Austrian capital; but I should explain to you that by the Austrian law that company is not allowed to work; that we, the Consolidated Company, are the Company that are working Austria for another company. We are in this position there, that we are now applying to the Courts to enable the Telephone Company of Austria to work the business in place of the Consolidated. It is perfectly independent; but by Austrian law we are obliged to put the item in our balance-sheet. I should tell you that the Edison-Gower-Bell shares are a growing asset, the same as that £28,000 in the Telephone Company of Austria is a growing asset. They are improving in value every day, I consider. What the value of them is I cannot fix. If you like to make a bid for the shares you may, of course, find it out in that way.

A SHAREHOLDER: Why are they not included in the assets?

The CHAIRMAN: Because they are against the £87,000 capital expenditure. They will become an asset I hope some day, and pay us a dividend. I shall be very much mistaken if they do not; I never lose sight of those shares, for they are a growing asset.

The AUDITOR (Mr. Griffiths), in reply to another shareholder, said that the reason why those shares which were referred to in the accounts in a note were not valued was that they were practically of an unassessable value at the present moment. It would be impossible for the Directors to say what the shares were worth. There was no market for them whatever, and if they put any valuation on the shares now it would be a mere guess, which would have to be varied from time to time, and thus affect the appearance of the balance-sheet without really affecting their position in any respect whatever.

The CHAIRMAN: I will now propose that the statement of accounts, the balance-sheet, and the report of the Directors, as now submitted to the meeting, be received and adopted, and that a final dividend of 2½ per cent. be paid, making, with the interim dividend previously paid, 5 per cent. for the year ended 31st March, 1887.

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the resolution, which was carried unanimously.

On the motion of Mr. A. H. Baker, seconded by Mr. H. Grewing, the retiring Directors, Mr. C. L. W. FitzGerald and Mr. Richard Van-Zeller, were unanimously re-elected to their seats at the Board.

The auditors, Messrs. John G. Griffiths and Arthur E. Green, were subsequently reappointed.

The meeting was then made extraordinary.

The SECRETARY having read the advertisement calling the meeting,

The CHAIRMAN said: Gentlemen, I have already explained to you what the reduction of our capital means, and therefore I will not detain you longer than just to move this resolution:—"That the capital of the Company be reduced from £243,787. 10s., divided into 224,850 shares of 15s. each, and 75,150 shares of £1 each, to £232,545, divided into 224,850 shares of 14s. each and 75,150 shares of £1 each, and that such reduction be effected by returning to the holders of the 224,850 shares that have been issued, paid-up capital to the extent of 1s. per share, and by reducing the nominal amount of such 224,850 shares to 14s. each."

Sir ALEXANDER ARMSTRONG seconded the motion.

The CHAIRMAN, in reply to a question, said that the reason why the money was being paid back was because the Directors found they could not use it.

A SHAREHOLDER asked whether the Company had some claim against Sir Julius Vogel?

The CHAIRMAN replied in the affirmative, but pointed out that it was an exceedingly difficult thing to sue a man in Australia.

The motion was carried unanimously.

The CHAIRMAN: We shall have to hold a confirmatory meeting within a month. We shall send you out the dividend warrants early next week. How long it will take to get the permission of the Court to return you the 1s. per share I cannot tell you, but it will be done as quickly as possible.

A vote of thanks having been passed to the Chairman and Directors the proceedings terminated.

CRICKET.

EASTERN TELEGRAPH COMPANY v. ST. MILDRED'S C.C.

This match was played on the West London Cricket Grounds, Wormwood Scrubbs, on Saturday, the 28th ult., and resulted in a decisive victory for the Eastern Company. Their opponents (mainly composed of *employés* in the Anglo-American Telegraph Company) made no stand against the destructive bowling of Messrs. McMillan and McDonald, their total being 36 runs. The Eastern Company, on the other hand, through the excellent play of Messrs. Hensman and Couper, secured 83 runs, thus leaving them victors by 47 runs. We annex the scores:—

ST. MILDRED'S.—Knowler, b. McMillan, 0; Clarke, c. Launders, b. McDonald, 9; Wran, b. McDonald, 3; Denton, c. Donaldson, b. McDonald, 1; Lester, c. Prosser, b. McMillan, 0; Constant, not out, 6; Alexander, b. McDonald, 0; Griffen, c. McDonald, b. McMillan, 1; Smith, run out, 0; Willis, b. McMillan, 12; Poulton, b. McMillan, 0; extras 4—total 36.

EASTERN TELEGRAPH COMPANY.—McMillan, c. Wran, b. Constant, 6; Prosser, run out, 5; McDonald, b. Constant, 0; Couper, b. Clark, 11; Finlayson, run out, 1; Hensman, b. Constant, 37; Donaldson, b. Clark, 2; Payne, b. Constant, 1; Grigor, b. Clark, 3; Sherlock, not out, 0; Launders, b. Clark, 9; extras 8—total, 83.

EASTERN TELEGRAPH COMPANY v. WALHAM GREEN C.C.

This match was played on the ground of the Walham Green C.C., Beaufort House, on Whit Monday last, and after a most pleasant game the Telegraph Company were declared the victors by an innings and 7 runs. Comment is hardly necessary, the annexed details of the scoring showing the state of game:—

WALHAM GREEN.—First innings—Alsop, b. McMillan, 14; Milner, b. McMillan, 3; Davies, b. McMillan, 5; Redsall, b. McMillan, 7; Wright, c. Lindsay, b. McMillan, 5; Salisbury, b. McMillan, 0; Hawkes, c. Finlayson, b. McMillan, 0; H. W. Smith, c. McMillan, b. Lindsay, 0; Brown, c. Morrison, b. Lindsay, 6; G. Smith, b. McMillan, 0; Pender, not out, 0; extras 1—total 41. Second innings—Alsop, b. G. C. Jack, 1; Milner, c. Finlayson, b. G. C. Jack, 12; Davies, b. G. C. Jack, 4; Redsall, b. Lindsay, 1; Wright, lbw., b. Lindsay, 3; Salisbury, b. Lindsay, 1; Hawkes, b. G. C. Jack, 27; H. W. Smith, not out, 2; Brown, b. Lindsay, 0; G. Smith, b. G. C. Jack, 4; Pender, lbw., b. Lindsay, 0; extras 5—total 60.

EASTERN TELEGRAPH COMPANY.—Prosser, b. Redsall, 28; A. Jack, b Redsall, 15; Finlayson, lbw., b. Redsall, 0; McMillan, c. Milner, b. Wright, 9; G. C. Jack, b. Brown, 39; Launders, hw., 0; Lindsay, b. Wright, 8; J. Morrison, b. Wright, 0; O'Shaughnessy, c. Alsop, b. Milner, 0; J. H. Jack, b. Wright, 0; Grigor, not out, 5; extras 4—total, 108.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th May amounted to £4,004.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for May, 1887, amounted to £48,057, and to £50,741 in the corresponding period of 1886.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this company for May, 1887, amounted to £36,495, and to £41,037 for May, 1886.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th May were £3,248, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NOTICE OF REMOVAL.—Messrs. Norman and Son, electrical engineers, of Glasgow, have changed their business address to 77, Waterloo-street, Glasgow, where they have taken commodious premises.

NOTES.

CABLES REPAIRED.—The cable of the Paris and New York Telegraph Company has been successfully repaired.

GLOUCESTER.—A telephone exchange has been opened in this town by the Western Counties and South Wales Telephone Company.

BENACRE HALL, LOWESTOFT.—Benacre Hall, near Lowestoft, which has been leased by Sir Arthur Guinness, is being fitted with electric light.

THE ELIESON ELECTRIC LOCOMOTIVE.—The Elieson locomotives commenced running upon the North London tram lines at Stratford on Monday last.

"WINDING MAGNETS FOR DYNAMOS.—Messrs. E. and F. N. Spon send us a copy of "Practical Directions for Winding Magnets for Dynamos," by Mr. C. Hering, of New York.

THE WEST COAST OF AFRICA CABLES.—Telegraphic communication has now been established with the following places on the West Coast of Africa, viz. :—Winnebah, Salt Pond, and Cape Coast Castle.

MEXICO.—Advices from the City of Mexico state that permission has been granted to an electric light company now putting in a plant at Puebla to utilise the water-power furnished by the River Atoyac.

FREEMASONRY.—Bro. James Hookey was installed W.M. of the Electric Lodge (No. 2,087) at the Mitre Hotel, Hampton Court, on the 28th ult., and Bro. W. H. Preece was presented with a handsome Past-Master's jewel on his retiring from the chair.

FATALITY BY LIGHTNING IN FRANCE.—On Sunday last at Figeac, in the department of Lot, during a heavy storm the church was struck by lightning. About thirty people were praying in the church at the time, and of these two women were killed and one man was severely burned.

THE RETIREMENT OF PROF. TYNDALL.—On his retirement from the chair of Natural Philosophy in the Royal Institution, Prof. Tyndall has been invited to a complimentary dinner at Willis's Rooms to be held on the 29th inst. The President of the Royal Society will take the chair.

TENDERS WANTED FOR PUBLIC LIGHTING.—Tenders are being invited for lighting the town of Alford "with gas or other light" up to May, 1888. Further information may be obtained from Mr. E. W. Rushton, town clerk, Alford, Lincolnshire, and tenders will be received up to the 25th inst.

BRIGHTLINGSEA, ESSEX.—The streets of this little town are at present lit by oil lamps. A motion to invite tenders for gas lighting has just been rejected by the local authorities by a small majority. It is questionable whether an electric lighting scheme would meet with any better fate, but it might be worth a trial.

ELECTRIC LIGHTING OF THEATRES MADE OBLIGATORY.—At Lyons the Mayor has issued a decree to the effect that in view of the recent deplorable catastrophe at the Opera Comique, all theatres, café concerts, and other public buildings in Lyons are, within five months from the present time, to be lit throughout by electricity.

THE POSTAL TELEGRAPH SERVICE.—In another column will be found an abstract of the recent debate in the House of Commons on the present position of the Postal Telegraph Service. The Postmaster-General has replied to the recent memorial, signed by the telegraphists at the Central Telegraph Station, on behalf of some amelioration of their position. Mr. Raikes expresses regret at his inability to accede to their wishes.

"FIVE FIGURE LOGARITHMS."—We have received a copy of "A B C Five Figure Logarithms, or logarithms with differences on a new and simpler plan, together with analytical factors, gas reduction tables, and other tables useful in physical and chemical laboratories, by Mr. C. J. Woodward, B.Sc., Principal of the Chemistry and Physics Department of the Birmingham and Midland Institute," published by Simpkin, Marshall and Co.

ROYAL METEOROLOGICAL SOCIETY.—At an ordinary meeting of this society, to be held at the Institution of Civil Engineers, at 25, Great George-street, Westminster, on Wednesday, the 15th inst., at 7 p.m., the following amongst other papers will be read :—"Note on a Display of Globular Lightning at Ringstead Bay, Dorset, on 17th August, 1876," by H. S. Eaton, M.A., F.R.Met.Soc.; "Ball Lightning seen during a Thunderstorm on 11th July, 1874," by John W. Tripe, M.D., F.R.Met.Soc.

THE ITALIAN GOVERNMENT AND THE TELEPHONE SERVICE.—The Commission appointed some time since by the Italian Government to consider the relation of the telephone service to the State telegraphs has presented its report. The principle that the monopoly of electric communication rests with the Government is laid down, but it is recommended that concessions for 20 years be accorded to established exchanges. Long-distance lines will also be permitted on the basis of a percentage of profits being paid to the Government.

A LONG RUN AT MONTREAL.—The Edison dynamo and Armington and Sims engine supplied to the St. Lawrence Sugar Refining Company, of Montreal, four years ago, are reported by Mr. A. J. Lawson as still in perfect condition. The commutator of the dynamo has only worn $\frac{1}{8}$in. in diameter in that time, although run day and night from Monday morning till midnight Saturday the year round without cessation. One set of brushes only have been used in a year, and both engine and dynamo have made the long run of forty-two days and nights, or 1,008 hours, without stop. Several of the lamps have given a life of 7,000 hours, and are not yet burned out.

THE RATING OF TELEPHONE WIRES.—At a meeting of the Glasgow Town Council it was reported that the attention of the assessor had been called to the telephone wires or apparatus in the city parish, and to request him to have them inserted in the valuation roll. Mr. Brechin said it had appeared to the committee that telephone wires should be assessed in common with telegraph wires, water and gas pipes, and many other things. The wires were erected by a company trading for profit, and it was only right that they should contribute their share to the assessments of the parish. In the meantime the committee were waiting to hear what the result of the communication with the company would be.

THE INSTITUTION OF CIVIL ENGINEERS.—The following awards, amongst others, have been recently made by the Council :—The Howard Quinquennial Prize to John Percy, M.D., F.R.S., Hon. M. Inst. C.E., in recognition of his researches on the Uses and Properties of Iron. For papers read and discussed at the ordinary meetings during the season 1886-87 :—A Telford Medal and a Telford Premium to John Hopkinson, jun., M.A., D.Sc., F.R.S., M. Inst. C.E., for his paper on "The Electric Lighthouses of Macquarie and of Tino." For papers printed in the *Proceedings* without being discussed :—A Telford Premium to Killingworth William Hedges, M. Inst. C.E., for his paper on "Central-Station Electric Lighting."

THEATRE LIGHTING IN LONDON.—We are pleased to note that the electric lighting of the London theatres is making

Digitized by Google

steady progress. Messrs. E. L. Berry and Co. write us on this subject as follows:—"We beg to inform you that Mr. Edwardes, lessee of the Gaiety Theatre, has now also taken the Empire Theatre, and has placed all engineering and electric lighting arrangements in our hands. We have also received instructions from Mr. H. J. Leslie to light up the New Lyric Theatre, in Shaftesbury-avenue, with electric light all over the house, including the stage. The electric light will be extensively used for stage effects, the lime light being entirely dispensed with. All the latest English and foreign improvements will be adopted."

THE LECLANCHÉ BATTERY FOR ELECTRIC LIGHTING.—The Leclanché cell has proved so great a success for telegraphic and domestic use that it is no wonder that attempts should be made from time to time to utilise the same chemical reaction for the production of the heavier currents required for electric lighting. All such attempts have hitherto failed, owing to the rapid polarisation of the cell. The latest suggestion for overcoming this difficulty is due to M. Jarriant, although, unfortunately, we cannot feel *very* hopeful as to the commercial practicability of the idea. M. Jarriant proposes to take four separate batteries, each capable of lighting the required lamp or number of lamps for one minute; he then employs a commutator driven by clockwork to switches on the batteries successively in turn for the time above mentioned. In this way each cell gets a rest for three minutes out of four. The clockwork is made to run for twenty-four hours.

THE LIGHTING OF THE LAW COURTS.—On the occasion of the Jubilee Banquets of the Law Society, which were held in the Great Hall of the New Law Courts on Saturday and Monday last, the hall was lit for the first time by Pilsen arcs, run in parallel with the incandescent lamps in the corridors. The lamps, which are of a recently improved type, were supplied by Messrs. H. F. Joel and Co., and will remain as a portion of the permanent fittings of the hall. We are informed that the "Improved Pilsen" lamps have also been recently supplied by the same company to the Admiralty, to the London University, the Apothecaries' Hall, Victoria Station, and to several mills for use in dye houses. During the banquets above referred to the reception rooms were lit by variegated lamps hung amongst the foliage of the plants. These lamps were supplied by Messrs. Baily and Grundy, who are also supplying some extra machinery for the permanent installation of the Courts.

THE USE OF ELECTRO-DISSOLUTION IN CHEMICAL ANALYSIS.—The *Chemical News* has a paper by Mr. H. N. Warren, describing some results obtained by the use of electricity in chemical analysis:—"By placing iron boride at the positive pole with a platinum plate as the negative pole of a powerful battery, and using dilute sulphuric acid as a solvent, in twelve hours all the iron had dissolved, whilst the boron and other impurities were precipitated. A similar result was obtained with ferrous sulphide, whereas with silicon iron and phosphide of iron, zinc, &c., the silicon and phosphorus respectively were only partially precipitated. In hydrochloric acid copper may be separated from arsenic, iron, zinc, &c., by electro dissolution; and in ammonia, copper, silver, zinc arsenic, and other alloys may be resolved into their constituent metals. Electro-dissolution has also been applied to the preparation of unstable compounds, such as potassium ferrate, &c."

AN ARC LAMP WITH PNEUMATIC REGULATOR.—M. Leibold, of Aix-la-Chapelle, has introduced an arc lamp in which the regulation is effected by the escape of air from a reservoir. The reservoir consists of a pair of circular metal plates, connected all around with thin leather like a pair of bellows or a concertina. The upper carbon holder is attached to the upper plate. A valve in the lower plate permits the reservoir to be filled with air when the upper plate is raised by pulling down a chain to which it is attached. The air can then only escape through a small flexible india rubber tube, and this tube is closed by the pressure of a stiff spring. The spring, however, is connected with the armature of an electromagnet, which is placed in a shunt-circuit; consequently, when the resistance of the arc increases the armature is pulled down, opening the tube and allowing the air to escape until the upper carbon has reached its proper position. The lower carbon is pressed upward by a spring.

RANGE-FINDING BY ELECTRIC LIGHT.—A simple and ingenious plan has been suggested by M. E. Genglaire for enabling an ironclad to determine the range of an object after nightfall. M. Genglaire proposes to mount two powerful projectors, one at the bow and the other at the stern of the vessel, and to converge their beams upon the object in question. Then noting the angles between the right line joining the two foci and the convergent beams, we can solve the triangle and determine the distance of the vertex. It is obvious that the method does not pretend to any great accuracy, but it seems to be capable of sufficiently close approximation for the purpose in view to make it worth while for the Admiralty to try some experiments in this direction. M. Genglaire also suggests that to facilitate the operation the vessel can be brought round until the two angles are equal, or very nearly so, and that reference can then be made to a table of distances previously prepared so as to avoid having to make calculations at the time.

THE ELECTRO-OSTEOTOME.—While the use of electricity as a therapeutic agent is still more or less beclouded by the multitude of quacks which thrive upon the folly of those who pin their faith most firmly to what they least understand, the employment of electricity in surgery is, upon the other hand, rapidly becoming more and more extensive. Electric cautery is now a recognised operation, and the electric laryngoscope is in use in all the hospitals of London. Probably, however, no more valuable application of electricity to surgery has yet been devised than that of the electric osteotome or bone-cutter, which has been introduced by Dr. Roberts, of New York. Operations for diseased bone have hitherto been carried out in certain cases by a process of a most primitive, not to say barbarous, character. Any one wishing to become acquainted with some harrowing details may consult a recent issue of *Health*. Dr. Roberts's instrument, however, effects in a few seconds what the most skilful surgeons have hitherto taken many minutes to perform. It consists of a minute circular saw, which by means of a tiny motor is made to revolve at very high rate of speed. By this means the bone can be cut in any required direction with great ease and rapidity.

THE BELL TELEPHONE PATENT IN THE UNITED STATES. The following paragraph from an American paper will give an idea of the present position of the great telephone patent case, in which the arguments before the United States Supreme Court have recently been concluded:—"There is much speculation among persons interested in the telephone cases as to the time when the decision of the Court in those cases will be rendered. So far as is known the Court has given no intimation of an intention to decide them at the present term. The prevailing impression among lawyers seems to be that if the Court has concluded to affirm the judgment of the lower Court an announcement to that effect will be made before the adjourn-

Digitized by Google

ment next week, and that the opinion will be prepared at the leisure of the Court during the summer vacation. If, however, the Court should decide to reverse the judgments it would probably be necessary to prepare the opinion at once for the guidance of the lower tribunals, and it is regarded as doubtful whether the Court has had or will have time enough to prepare an opinion as long and elaborate as that which a reversal would make necessary. In such a case, therefore, the decision would probably not be announced until next term."

An Electrical Exhibition in New York.—At the meeting of the New York Electrical Society, the electrical section of the American Institute, held on May 25th, the project of holding an electrical exhibition in this city next autumn under the auspices of the society was brought forward, and received the hearty approval of the members. This exhibition, which is to be held in the Exhibition Hall of the American Institute, and is intended to include all the applications of electricity, will be the first of its kind that has ever been held in New York. The American Institute has signified its willingness to aid the society in its work in every possible way, and the American Institute of Electrical Engineers has also assured the society of its co-operation and support. It is probable that a course of lectures which is now being organised by the American Institute of Electrical Engineers will be in some way, through the agency of the society, connected with the educational work done at and by the exhibition. The details of the exhibition will shortly be made public, and thus ample time will be afforded for the preparation of intending exhibits. We understand that further information on the subject can be obtained from the president, Mr. J. M. Pendleton, 49, Broadway; Mr. J. Wetzler, secretary, 175, Potter-building; or Mr. C. W. Hull, superintendent of the American Institute, Clinton Hall.

Photographs of Lightning.—The following circular letter has been issued by the Council of the Royal Meteorological Society (whose address is 30, Great George-street, Westminster) and has been forwarded to a large number of amateur and professional photographers throughout the country:—"Sir: The Council of the Royal Meteorological Society are desirous of obtaining photographs of flashes of lightning, as they believe that a great deal of research on this subject can only be pursued by means of the camera. The council would esteem it a great favour if you, or the institution which you represent, could give them any assistance in this matter, either—(1) By sending them copies of any photographs of flashes of lightning that may have been already taken; (2) by endeavouring to procure them yourself: or to interest others in the work. It may perhaps be well to mention that the photography of lightning does not present any particular difficulties. If a rapid plate and an ordinary rapid doublet with full aperture be left uncovereed at night during a thunderstorm for a short time, flashes of lightning will after development be found in some cases to have impressed themselves upon the plate. The only difficulty is the uncertainty whether any particular flash will happen to have been in the field of view. The council hope that now the thunderstorm season is approaching, many photographers may be found willing to take up this interesting branch of their art.—I am, Sir, your obedient servant, William Marriott, assistant secretary."

The Phonograph.—According to an American journal, Mr. Tainter, who has long been associated with Prof. Alexander Graham Bell, of telephone fame, has taken up the Edison phonograph at the point where he left it, and developed it from a toy to an article of commercial value. Before long the new instrument will be placed upon the market. It is constructed on the same principle as the phonograph, but instead of giving out a squeaking, metallic sound, as when the sheet of tin foil was used, it now produces a full, sonorous sound, which can be distinctly heard and understood in any part of an ordinary room. The conversation is recorded upon thin sheets of wax in shape of a tube placed upon a cylinder. One of these little tubes will hold 1,000 words. A merchant who has forty letters to answer can sit before one of these machines, turn the crank, and talk his answers directly into the machine, which records them upon the wax tube in the same manner as in the old phonograph. Afterwards one of these little tubes can be slipped off the cylinder and sent by mail to any part of the country. When received it will only be necessary to put the wax tube into a similar machine, and it will reproduce the words of the original speaker as often as may be wished. The thin wax tubes will be on sale at stationery stores at about the same rate as letter paper. The general employment of the phonograph would be to a certain extent a preventive of forgery, since it reproduces the exact voice of the speaker, so that those who are familiar with it will recognise it at once.

A.D. 1622.—A correspondent of the French journal *Cosmos* states that in a curious old work printed at Paris in 1622 there occurs a remarkable passage, of which the following is a translation:—"We may also tell you this great and wonderful secret, which a certain German has shown to King Henry, and who, by his industry and dexterity, is able to speak and to converse with those who are far away, and this by means of the magnet. He first rubs together two needle magnets, and then places them each separately upon two clock dials, around which are engraven the twenty-four letters of the alphabet. If, then, they wish to speak together, or to make each other understand what they would desire, they move one needle around until it has pointed to the letters which are necessary to make the words and sentences that they would say, and as they turn one needle so also the distant needle turns, making always the same movement. The King seeing this wonderful secret forbade him to divulge it, fearing that thus would be opened very dangerous communications between the armies of his enemies and their besieged towns." The title page of the work in which the above passage is said to occur (on the 247th page) is as follows:—"L'incredulite et mescreance du sortilege plainement convaincue Par P. de l'Ancre, conseillor du Roy en son conseil d'Estat à Paris. Chez Nicolas Bvon, ruë Sainct-Iacques, à l'enseigne Sainct-Claude et de l'Homme Sauuage, MDCXXII." The notion that two magnetic needles by being rubbed together would afterwards move in sympathy finds a place in more than one book of marvels of the 17th century, but the above date is, we believe, the earliest to which it has yet been traced.

Remarkable Atmospheric Phenomenon.—In *Nature* of June 2nd Mr. E. J. Lowe, of Shirentown Hall, near Chepstow, gives the following description of a remarkable atmospheric phenomenon witnessed in his neighbourhood on April 26th, 1887:—"A phenomenon was seen here this even ing quite distinct from anything I have before observed. It was an exact copy of streams of aurora borealis rising from a low arch, but instead of being in the northern heavens it was near the south horizon. The sky was cloudless, except a long thundercloud which extended from near south-south-west to almost south-south-east, the upper portion of this cloud being about 12° above the horizon. From this cloud issued from one to three streams of conspicuous white light, the north-easterly stream being the largest and brightest, and this continued visible from 9:40 until 10:5 (the others were only

Digitized by Google

seen for five minutes). The streams were at an angle of about 53°, and moved slowly easterly (the cloud moving in the same direction). The longest stream reached an altitude of 25°, and at 10 o'clock exactly (G.M.T.) the base was immediately over the Avonmouth Lighthouse. The light of the streams was more persistent and less flickering than is usually the case with aurora borealis. There was also a confused luminosity behind the cloud, which varied considerably in brightness; this made the outline of the cloud at one time distinctly visible, and at another scarcely discernible; this also gave the clouds a black appearance. After 10 p.m. other clouds rose above the cumulo-stratus, and the streams became hid. Three hours afterwards there was a snowstorm, and the ground was white till 7 a.m. Reports from Somerset, Dorset, and Devon would be valuable."

SOIRÉE OF THE ROYAL SOCIETY.—On Wednesday evening last, at Burlington House, the Royal Society gave a soirée, at which upwards of five hundred guests attended. The exhibition of electrical experiments and apparatus formed, as usual, one of the most interesting features of the evening. The beautiful phosphorescent effects produced by the electric discharge over rubies, diamonds, and emeralds, were shown on a scale of unusual magnificence, some very fine jewels being lent for the purpose by Mr. Streeter. Dr. Sclater had also sent from the Zoological Gardens a very fine specimen of the electric eel, and some few of the guests were brave enough to pull its tail for the edification of lady friends. The greatest possible interest was also taken in the arrangements made by the United Telephone Company for enabling the guests to listen to the performance of *Ruddigore* at the Savoy. No less than 88 receivers were placed on the circuit, so that although each listener usually secured a pair of telephones, it would have been possible for 88 people to have heard simultaneously. The opera was rendered with excellent effect, and greatly delighted the guests. We may mention in passing that with one exception this is the largest number of telephones that have ever been switched on to a theatre, at any rate in this country. The exception is also to be credited to the United Telephone Company, who once connected 120 receivers between the Bristol Hotel in Bond-street and the Comedy Theatre. In addition to the performance of *Ruddigore*, telephonic music was heard on Wednesday evening from Brighton. In this case an Edison loud-speaking receiver was employed, and a cornet solo performed at Brighton was rendered audible all over the room. Altogether the soirée was one of the most interesting of recent years.

THE VAN DE POELE (OVERHEAD WIRE) SYSTEM OF TRAMCARS.—The following testimonial to the simplicity and efficiency of working a tram line on the overhead conductor system will be read with interest, even though the system is one scarcely likely to come into extended use in this country. In a recent letter to the Van de Poele Company, Judge J. E. Harriman, the President of the Electric Street Railway at Appleton, says:—"Our road, as you know, commenced operating August 16 last; except a few weeks to get the track all right and get the cars limbered up, we had a continuous run. The snow we found we could master, and did with the electric cars, pushing a snow plough which we made ourselves. The overhead wire, which we feared would give us the most trouble, has never bothered us to exceed two hours twice this winter, although the telephone and telegraph wires were made useless for their business many times. We know that we have made more hours and better time all winter than we could possibly have done with animal power. We operate our road three miles, in schedule time, with three cars regularly, and the time does not vary a minute any day at the switches or at the end of the line. We run five cars on busy days. I do not need to elaborate—we cannot find any fault with the system. The wires have not been touched since last fall, and the motors are doing their work perfectly. The travellers are doing well. The dynamo I have not heard from in a long time, although a new man is running it. All of the help that we have are new at the business, yet all runs like a clock. Hundreds have been here to examine our road, and without an exception have been perfectly satisfied that electricity is the future power for street railways on account of its simplicity, reliability, rapidity, and neatness. You may quote our company and our citizens as for it first, last, and all the time."

JARMAN'S ELECTRIC TRAMCAR.—In our issue of October 29th, 1886, we gave some description of a model tramcar, driven by an electro-motor, and constructed by Mr. Jarman. This "system" (of which, so far as it is unique, we expressed our own opinion at the time, somewhat to Mr. Jarman's discontent) has now been placed in operation at Brixton, and we should still be very pleased to hear of its permanent success. There is no reason whatever, so far as we know, why it should not stand a very fair chance of success, if only Mr. Jarman selects a reliable form of storage battery, an efficient motor, and a good mechanical gearing. Our criticism is merely that if these arrangements are reasonably perfect the advantage of duplicating the motor for forward and backward running—which is Mr. Jarman's patent—is not great. The following description appeared in the *Daily News* of June 7th:—"Jarman's self-contained electric tramcar was on view yesterday in Electric-lane, Atlantic-road, Brixton, S.W. The invention shows a marked improvement over previous electric cars, the advantage lying mainly in the fact that two armatures are fitted into the electro-motor instead of one. They are worked alternately on the forward and return journeys, each being thus constantly cooled. The weight of the car itself is 3 tons, and the electro-motor, storage cells, &c., bring the weight up to about 5 tons 6 cwt. The brakes of the car are of a novel description, the brake-wheels being placed upon the axle of the electro-motor. It is believed that the cost of the electricity required to propel the car will not exceed 2½d. to 3d. per mile run. A signal bell is placed at each end of the car, and this bell can be worked by the driver's knee. Yesterday's experiments upon a line with an incline of 1 in 40ft., and including a curve having a 43ft. radius, were highly satisfactory. Considerable speed was attained, the car responding readily to the brake, and its direction was easily reversed."

ELECTRIC LIGHTS IN LABORATORIES.—Mr. H. G. Torrey, of the United States Assay Office, writes to the *New York Engineering and Mining Journal* on the subject of electric lighting in laboratories as follows:—"Sir: A short time ago I learned that one of the prominent smelting companies in this vicinity, in the equipment of its new laboratory, had omitted the incandescent electric light on account of its possible effect upon their balances by magnetising and electrifying them. Although the Edison Company does all its weighing of meter zincs on balances which are close to their electric lights, I thought it might be interesting to some of your readers who are daily using delicate balances, and whose work may be injured by the slightest variation in the instruments employed, to know exactly what effect electric light currents have on delicate weighing. To determine this, experiments were made under my supervision by Mr. Taylor, one of my assistants. Magnetising effects were examined upon balances made by Becker, Troemner, and Oeterling with

Digitized by Google

uniformly negative results, and an examination of these balances showed that there was no iron or steel in their construction, with the exception of a minute steel pin at the stirrup and the steel knife edges. With the view of determining what the effect would be were there any considerable masses of iron in the construction, an iron wire about 1½in. long, weighing 200m., was placed on one pan and exactly balanced. The current being passed above this wire and parallel to it, a very slight magnetic effect was produced when the distance did not exceed one-eighth of an inch. As it is impossible to run the conducting wire closer to the balance than six inches, the magnetic effects, even though there be iron in the construction of the balance, are inappreciable. The electrifying effects of static electricity are produced by dynamic electricity only when the potential is very high, and none whatever are noticeable with the very low potential of the incandescent light current."

THE LIGHTING OF THEATRES.—The manager of the Prince of Wales Theatre, which is lit throughout by electric light, writes as follows to the editor of the *Morning Post*:—"Sir: In reading your reports of the terrible calamity which has recently occurred at the Opera Comique in Paris, in aid of the sufferers of which I have arranged to give my theatre for a *matinée* on Wednesday, June 8th, I think it must be allowed that the panic was caused, or at any rate greatly aggravated, by the fact of the theatre being in total darkness, owing to the gas having either gone out or having been turned out, whereas had the electric light been in use, as it is here at the Prince of Wales's and other London theatres, no such terrible result could have happened. In support of this it may interest some of your readers when I tell you that only a few weeks ago, during the performance here of the evening farce, one of the gas bags used in connection with the lime light (which since the evening in question I have entirely dispensed with in the theatre) exploded, the concussion being sufficiently great to put out the gas in the auditorium. All confusion, anxiety, or panic were, however, averted owing to the electric light being in use throughout the theatre, for simultaneously with the explosion the lights not used during the performance were switched on before the audience could realise what had occurred. I went to the footlights, explained what had happened, and ordered the iron curtain to be lowered. Every one remained in his seat, and the performance was continued after some ten or fifteen minutes' delay. Did your space permit I could easily explain how, with timely and proper precautions, such as fire drill for the men, extra and special exits from every part of the house, with doors opening outwards on to the street, only requiring a push from the inside to open them, and with iron doors disconnecting the auditorium from the stage, and the stage from the artists' dressing rooms, as is the case in this theatre, every possible danger of panic or disorder can be avoided both before and behind the curtain."

BRITISH VERSUS AMERICAN MODES OF DOING BUSINESS.—The following anecdote is told by a correspondent of the *Electrical World* of New York. We reproduce the story without any feeling of pride in the matter; but at a time when the conduct of business amongst the electrical engineers of this country is under discussion it will not be amiss to give one more illustration of "the way in which electric light business is lost"—and gained:—"About a year ago the city of Puebla asked for estimates for illuminating its streets by the electric light, and an agreement was entered into between the city and an Englishman for a plant of 100 lights. The contract was drawn up by the city authorities, and they did not seem to think that there was any practical difference in the systems, for there was no particular system named in the contract. The work was not proceeded with in time to permit of having the plant installed at the date required by the contract. This, it is said, was due to a lack of funds on the part of the contractor. A new arrangement was made, however, which gave him until the 15th of March of the present year to carry out the scheme; but still owing, it is said, to lack of funds, the apparatus did not arrive until some time after the 15th of March. In the meantime, the representatives of a leading American company, who had had their eye on Puebla, made an exhibit of their system to the Puebla Government, and succeeded in getting the old contract annulled on the 15th of March, when it was apparent that the other contractor could not install the plant in time. Not only did they get the old contract annulled, but they obtained a new one in their own favour for 125 2,000 candle-power lights to be run by water-power supplied by the falls of the Atoyec River, eight miles from Puebla. According to the estimates made, there will be a very considerable saving by the use of water-power. Coal is so expensive in Mexico that if this were used the cost of the 125 lights would be about 20,000 dollars a year, whereas, by the use of water-power the expense is only 2,000 dollars."

THE LATE THOMAS STEVENSON.—We extract the following from a charming biographical notice of his eminent father by Robert Louis Stevenson, the popular novelist, in the current number of the *Contemporary Review*:—"But the great achievement of his life was, of course, in optics as applied to light-house illumination. Fresnel had done much; Fresnel had settled the fixed light apparatus on a principal that still seems unimprovable, and when Thomas Stevenson stepped in and brought to a comparable perfection the revolving light, a not unnatural jealousy and much painful controversy rose in France. It had its hour; and as I have told already, even in France it has blown by. Had it not it would have mattered the less since all through his life my father continued to justify his claim by fresh advances. New apparatus for lights in new situations was continually being designed with the same unwearied search for perfection, the same nice ingenuity of means; and though that holophotal revolving light perhaps still remains his most elegant contrivance, it is difficult to give it the palm over the much greater condensing system, with its thousand possible modifications. The number and the value of these improvements entitle their author to the name of one of mankind's benefactors. In all parts of the world a safer landfall awaits the mariner. Two things must be said; and first, that Thomas Stevenson was no mathematician. Natural shrewdness, a sentiment of optical laws, and a great intensity of consideration, led him to just conclusions; but to calculate the necessary formulæ for the instruments he had conceived was often beyond him, and he must fall back on the help of others, notably on that of his cousin and lifelong intimate friend, *emeritus* Prof. Swan, of St. Andrew, and his later friend Prof. P. G. Tait. It is a curious enough circumstance, and a great encouragement to others, that a man so ill equipped should have succeeded in one of the most abstract and arduous walks of applied science. The second remark is one that applies to the whole family, and only particularly to Thomas Stevenson from the great number and importance of his inventions; holding, as the Stevensons did, a Government appointment, they regarded this original work as something due already to the nation, and none of them has ever taken out a patent. It is another cause of the comparative obscurity of the name, for a patent not only brings in money, it infallibly spreads reputation; and my father's instruments enter anonymously into a hundred light-rooms, and are passed anonymously over in a hundred reports, where the least considerable patent would stand out and tell its author's story."

THE FARADAY DISC DYNAMO MACHINE OF JEHL AND RUPP.

An essential disposition of every disc armature dynamo is that a greater or less number of alternating magnet poles are arranged around the circumference of a circle, faced by an equal number of respectively opposite poles. In the space between these two rows of magnetic poles, viz., in the alternating magnetic fields produced by them, revolves the disc armature, which consists of a suitable number of copper bands or coils, likewise arranged around the circumference of a circle.

The electromotive force generated is proportional—

(1) To the area of every armature coil.
(2) To the number of armature coils.
(3) To the intensity of the total magnetic field.
(4) To the number of magnetic poles in one row.
(5) To the speed of the armature.

In all disc dynamos constructed till now there is generally a great number of small electro-magnets whose cores lie parallel to the shaft or axis of the armature. In the dynamo which is about to be described, and which has been designed by Jehl and Rupp, there are, on the contrary, only two magnets of considerable iron mass. Such magnets are far superior to the former. To show this we will compare a magnetic system having four pairs of opposite poles with another system consisting of, say, twelve pairs of opposite magnetic poles, assuming the iron mass and the magnetising powers (ampere turns) to be the same in both cases.

In the first case each coil of the armature passes through four alternating magnetic fields in one revolution, whereas in the second case it passes through twelve alternating fields. Of course, if the intensity of the field produced by two opposite poles were the same in both cases, the electromotive force produced by the second arrangement would be three times greater than that produced by the first arrangement.

But now the single magnets in the first case being three times greater than in the second, the intensity of the field produced by two such opposite single magnets is in the former far more than three times the intensity in the latter, for, as it is well known, the magnetic capacity of the same mass of iron is far more useful in a single piece than if divided in smaller pieces, to say nothing of the difference of weight of copper it takes to wind the two systems.

There is also another loss of magnetism in nearly all disc machines, and this is due to the close parallel position of each two adjacent magnet cores—that is, the lines of force commence to jump from one core to the other, being dense at the poles and gradually becoming less dense as we approach the neutral point. These lines are entirely useless, and therefore lost, as the armature does not cut through them. The lines that pass directly from one pole to another and are cut by the armature are called the useful lines, and the ratio of the useful and lost lines determines the efficiency of the magnet. Bollmann, in his disc machine, has tried to enlarge the capacity of his magnetic system (he has a large number of small electro-magnets) by short-cutting or overbridging the magnetic poles in a peculiar manner. But he applies that principle (from my point of view) in an entirely wrong way. Firstly, by his arrangement he gets all north poles on one side of the armature and all south poles on the other side. His electromotive force is therefore only caused by the approach and removal of the armature coils in such places where the intensity of a single magnetic field becomes greater or less, and this electromotive force must necessarily be less than if, under the same circumstances, the field were alternating. Also there is some loss due to the winding of the magnets in such systems where several cores are wound separately but to give the same polarity. We see in such cases where two such cores with their windings are parallel to each other, the current in the adjacent coils passes in opposite directions, and so tends to produce neutralisation of the magnetising force. Now Jehl and Rupp have designed a system of electro-magnets which are free from all the defects mentioned above. In Fig. 1 we see that they have taken four poles. The north poles are diagonally opposite one another, and so also are the south poles. Fig. 1 shows only one half of the magnetic system, there being two such squares between which the armature revolves. It will be seen that the cores lie parallel to the plane of the armature, and at right angles to the axis, and not parallel to the latter, as in other machines. Of course, it is understood that a north pole on one side faces a south pole on the other, and thus the fields become alternating. It will be seen that such a system contains a large mass of iron, and will produce a very strong, dense, and alternating magnetic field. Such a system has very little magnetic resistance. Then, again, we see that the loss of lines of force in the machines spoken of above is here entirely avoided. The armature turns between the two squares forming the magnetic system and the lines of force commencing from a dense positive direction grow thinner just to the neutral point, where they assume a negative direction, gradually becoming denser till the densest part is reached, and then again becoming weaker to the neutral point, and so on. All these lines are always cut by the armature, so that all lines which pass from one square to another must necessarily come in the path of the armature. Thus by such a disposition four magnetic fields with large area and great strength is obtained. Another advantage of such a magnetic system is that all parts of the cores are effective, and wire wound from one pole-piece to the other; there being no yoke, which is a general thing in other machines, only serves for the conduction of the lines of force, and is not generally serviceable for their generation. It will, however, be shown later that some modification of this system has been introduced, with the advantage of saving copper in the field.

The Armature.—In all disc machines till now constructed the armature is built up of copper bands, either in a zig-zag form around the centre of the armature or consisting of coils placed together around the centre. In both these cases there exists always a considerable space where there is no copper; or if in the latter case the single coils are made of many turns, each becoming gradually smaller, it is evident that the electromotive force due to some of these additional turns is almost insignificant in comparison to the increase of resistance due to these additional coils or turns. Jehl and Rupp have succeeded in constructing an armature where all space inside the outer circumference is occupied by copper, and in which each and every coil or turn has the same area. This fact will be shown later on. They take a strip of copper, as shown in Fig. 2, which has a cut, say of 1 5 mm. in thickness, and terminating to about 40 mm. from one end. At this end, and on both sides of this strip, are incisions which serve the purpose of holding these pieces of copper to the shaft, by means of two plates, which have at their outer circumference flanges which fit into the incisions. It is evident that instead of incisions we may have projections, as shown by the dotted lines in Figs. 2 and 3. They then take this strip, and put it in a form, and press it into a shape somewhat as shown in Fig. 4. Fig. 4 shows, however, only one-half of one turn and three-fourths of another, showing also how one turn is connected to the other. It is evident, therefore, that each coil fits into one another, and the connections are made at the outer circumference by means of small caps, as shown in Fig. 4. It will be seen from this construction that every coil has the same area, and each and every coil is so divided that one-half is in the inside its neighbouring turn, while its other half is on the outside of this neighbouring turn; also that one-half of every turn is on one side of the armature, while its other half is on the other side. We can then place one turn inside the other until we complete the armature. Of course it is understood each turn is insulated from the others. It must be understood that this construction is not a simple mutual overlapping of coils, which would cause an oblique or sloping position of the coils, but is a mode by which each half of the coil lies in a different yet parallel plane, and between these two planes is placed some insulating material. Fig. 9 shows about one-fourth of the armature, *a* is the part of a coil to which the commutator bar is connected, *b* is the part where the flanges of the plates that are attached to the shaft rests—(these plates and shaft are not shown), *c* is a ring of

Digitized by Google

wood with teeth, which teeth pass into the space between each connecting cup *d*, while on the top of this ring wire is wound to hold or bind all together.

Again, consider a single turn or coil of the armature, as shown in Fig. 4. This coil or turn can be made from a strip of copper, as already shown. If, however, we saw or make a strip of copper as in Fig. 3 we can form several from one piece. The advantage of this is that it saves soldering. However, in practice it will be found more convenient to make them from a single strip, as in Fig. 2.

Fig. 1

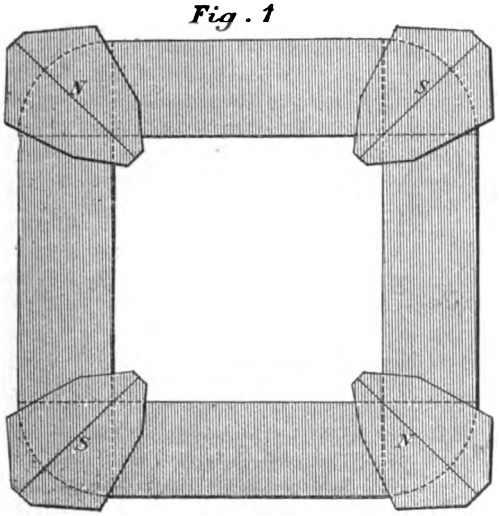

Fig. 2

Fig. 3

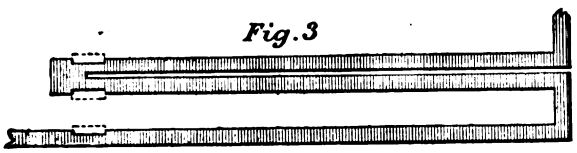

Fig. 4

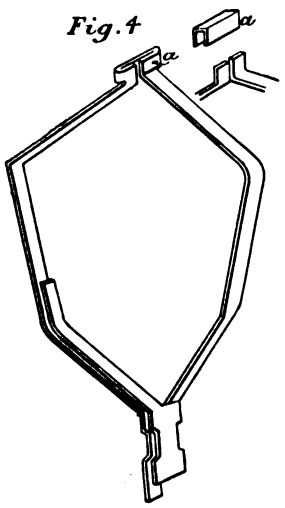

Fig. 5

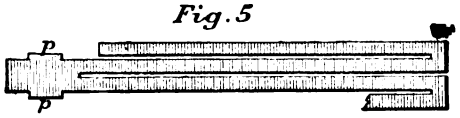

Fig. 6

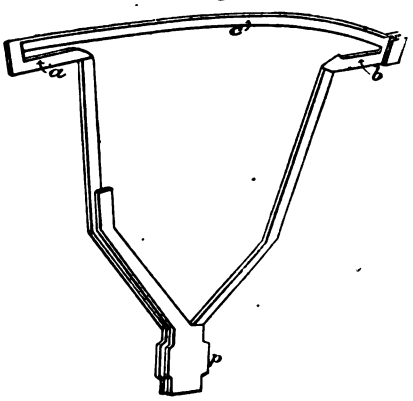

Fig. 7

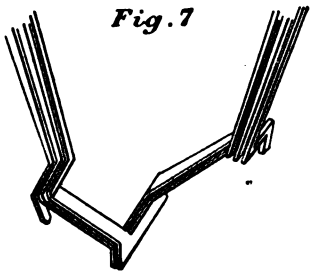

Fig. 10

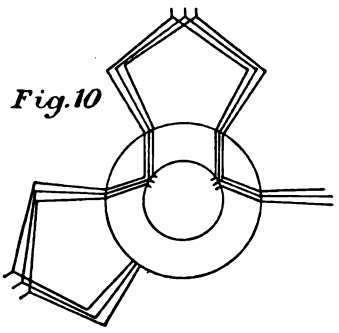

Fig. 8

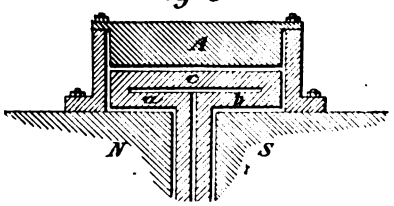

Fig. 6 shows another form of a turn, differing somewhat in shape from Fig. 4, but in principle the same. This is a very good arrangement, as the surface or area is somewhat larger than in Fig. 4. To make such a coil, we take a strip of copper and cut it as shown in Fig. 5. It will be seen that instead of incisions it has projections, P, which fit into a groove in the plate attached to the shaft. These projections P have the advantage that the area of that part of the turn or coil is increased instead of diminished, as is the case with the incisions, and thus that part is not apt to heat; its disadvantage, on the other hand, is that there is some waste of copper when constructing such a form, while when making it with the incisions the copper is nearly all utilised, with the exception of that little space where the incisions are cut. It will be noticed that in Fig. 6 the top part of the turn makes connection from the right-hand arm *a* to the left-hand arm *b*. This top part, *c*, is the connecting band that makes connection with one turn to its neighbour—that is, it forms part of one turn, and its end is soldered on to the next. Supposing we are looking at the armature from the front—that is, looking at right angles to the shaft—we will have a view as shown in Fig. 8, where *a* and *b* are the right and left hand arms, while *c* is the top connecting band. N and S are the two poles, while if we place a piece of iron A in the position as shown in the drawing, lines of force are drawn over in that direction, and the top parts of the turns therefore cut them.

It is evident that the number of coils in an armature depends upon the inner circle. This inner circle can be entirely filled up with copper, while going away from it space

Digitized by Google

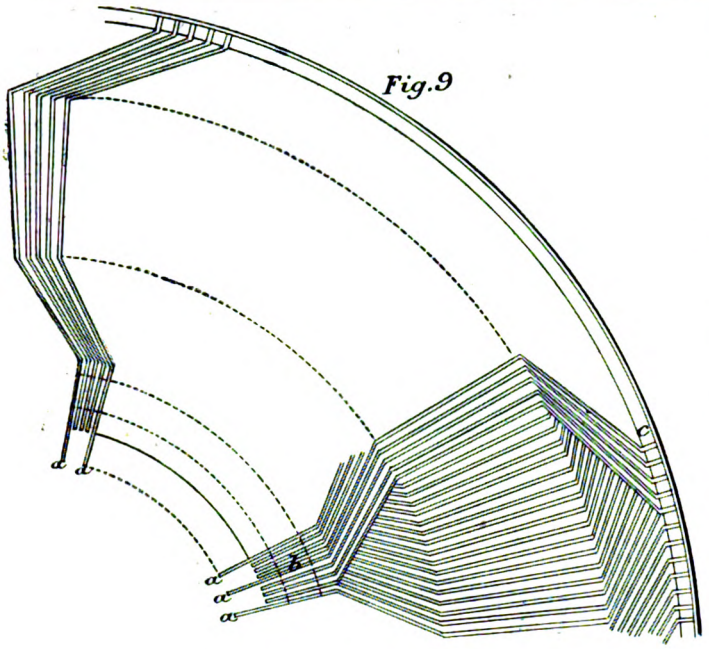

Fig. 9

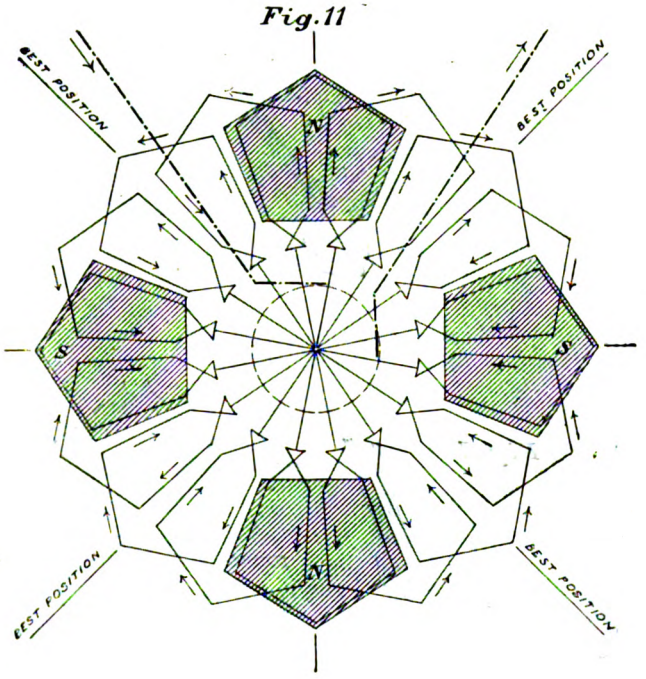

Fig. 11

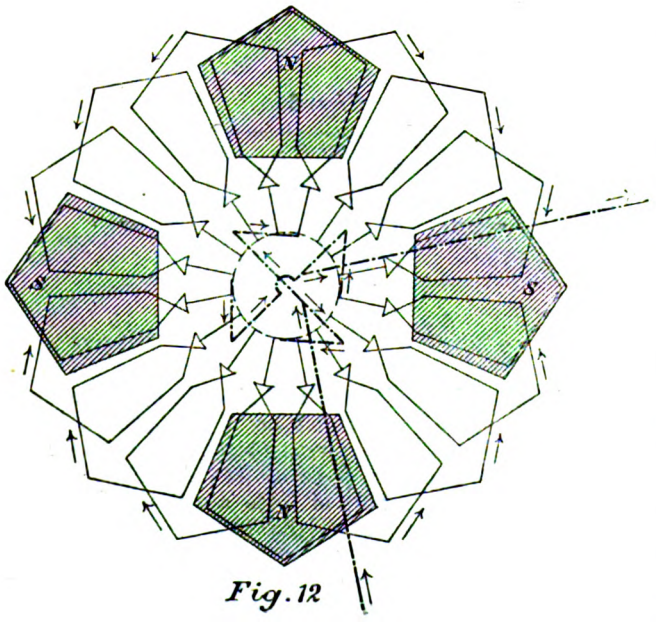

Fig. 12

begins to form. This is got over by making the lower parts thinner but broader than the upper. Thus the section of the copper is not altered, but these parts being thinner admit more coils to be placed upon, or rather around, the inner circle. This arrangement is shown in Fig. 7.

It may be mentioned that this principle of Jehl and Rupp of dividing every turn in two halves, which lie in different yet parallel planes, as already described above, can also with advantage be used in building an armature in the zigzag form, so that all space within the outer circumference is filled up. Fig. 10 shows this converting of coils into this zigzag form.

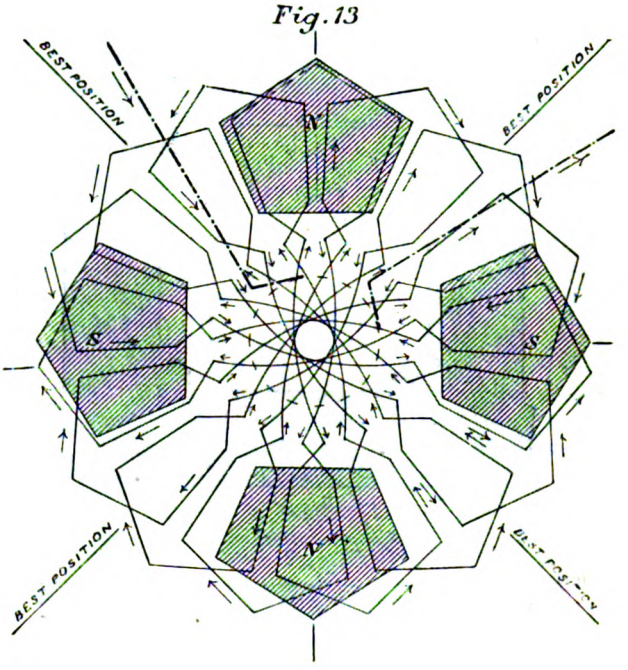

Fig. 13

To gather the currents induced in the coils, there are different ways depending on the number of coils in the armature. If, for example, we have a number which can be divided by four, we can connect them as shown in Figs. 11 or 12, both

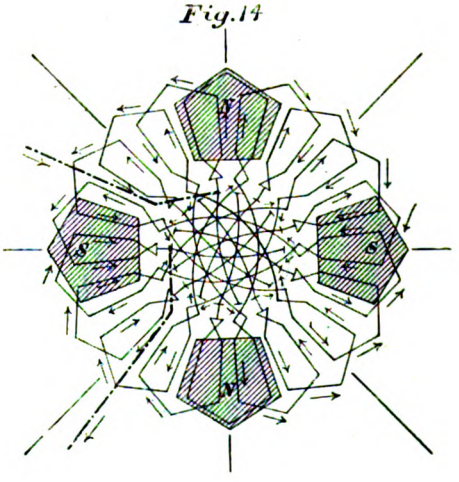

Fig. 14

of which in principle are about the same. In Fig. 11 the commutator blocks, which are diametrically opposite each other, are connected together by putting every pair of opposite coils in multiple arc, thus giving for the whole machine double the current and half the electromotive force.

If we have an odd number of coils the connections are made as shown by Fig. 13. This way puts all coils in series, and thus we get double the electromotive force and half the current.

Then, again, if we have such a number of coils as can be divided by two but not by four, the connections are made as

Digitized by Google

shown in Fig. 14. This is an entirely novel way. The coils are also all in series, and yet all the commutator bars diametrically opposite each other are connected together, and on one side the bars appear to be without connection with the coils.

However, when the brush touches that block it collects the current of the coil which is attached to the opposite block. Of course, in all cases described the number of commutator blocks must be equal to that of the coils in the armature.

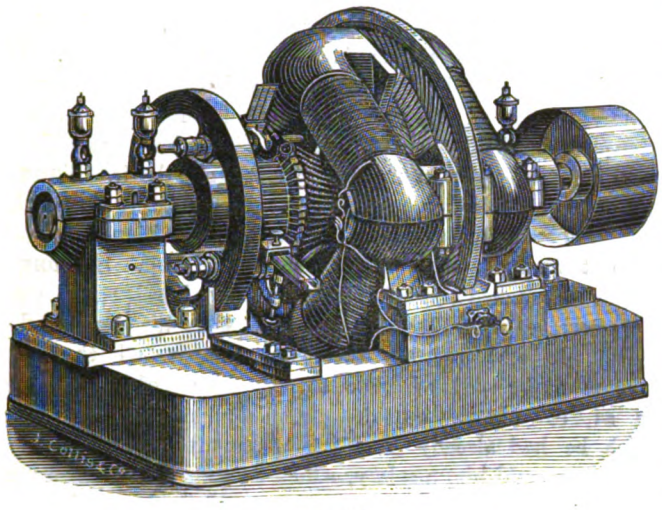

Fig. 15.

Fig. 15 shows the disc machine complete, and which size is capable of giving 350 amperes and 110 volts, using about 5 per cent. for the field-magnets and running at 735 revolutions per minute. The copper in the armature weighs about 24 kilogrammes. The machine is 80 centimetres high and 130

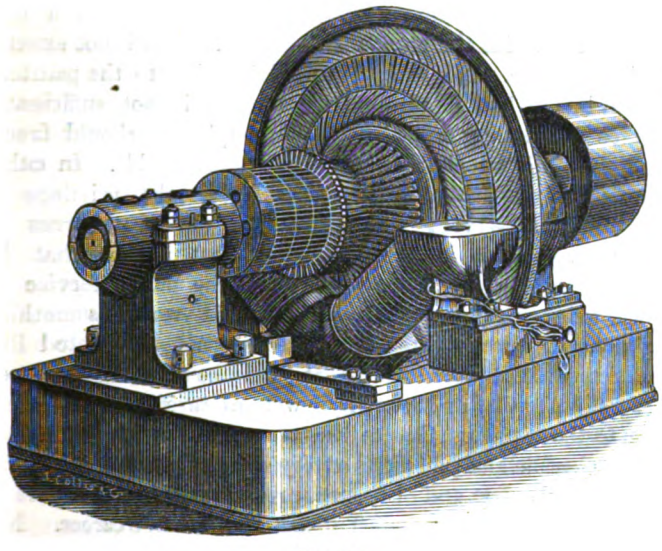

Fig. 16.

centimetres long. Fig. 16 shows the same machine with a fourth of its magnetic system taken off so as to get a better view of the armature, &c. E. D. F.

New Method of Making Porous Earthenware.—A new method of making porous earthenware has lately been used very successfully in Germany. The clay is tempered and worked to the proper consistency with a mixture of water and naphthaline. The objects, after being formed, are placed in a dry kiln and gradually heated until the naphtha is all expelled, leaving the object perfectly and uniformly porous. The dry kilns are so built that all the naphthaline is drawn off and con densed, so that it can be used over again.

"VISUAL SYNCHRONISM."

The visual appearance of the paragraph quoted below, taken from a recent number of an American journal, will doubtless synchronise in the mind of the enlightened reader with feelings of a somewhat mixed character; for unhappily, we fear, that the profound admiration which all must feel for the man who has at last obtained a practical solution of the problem of "seeing by electricity" will get so mixed up with the dazzling vision of ten thousand per cent. "in a short time," that Mr. Rogers's fame as a man of science will be obscured. This would be so sad that we are inclined to recommend our readers to be content for the time being with mastering the scientific aspect of "visual synchronism," and to allow the Yankees to reap the promised pecuniary harvest. We are, however, sorry that for the present our information upon the subject does not extend beyond the following paragraph:—A special despatch from Washington says:—"J. Harris Rogers has published a pamphlet describing a new invention of his entitled 'Visual Synchronism.' Mr. Rogers asks for $100,000 to organise a company to work the patent, and promises a return of $100 for $1 on the investment in a short time. As to the practical applications of 'visual synchronism' he says:—'It enables one in effect, though not in reality, to see by electricity any number of revolving wheels, or moving mechanism, thousands of miles away, so that absolute harmony, or synchronism, is preserved to them all. Of course, many applications of the new system may be made, wherever wheels or moving mechanism may be utilised in telegraphy, electric locomotion, horology, printing, &c. The new synchronism may now be seen by any one, as absolute, and working perfectly for all practical purposes, at an almost incredible velocity. It solves the greatest problem of electrical communication, and will render messages so cheap, it is predicted, that all Governments must adopt it, and ultimately send their letters by wire instead of rail.' Mr. Rogers believes that by this system he will be able to transmit photographs, landscapes, and handwriting by electricity."

In conclusion Mr. Rogers waxes eloquent. He says:—"Capital is invited; but statesmen, of the high-stepping variety, who expect to get control of the patent by promising their great names to float the stock, while conspiring to pocket money without risking their august names on the stock promised, 'need not apply.' We want honest business men. A plague upon greatness. If my earlier patents got mixed up against my will by statesmen, with a Government job, the present enterprise should not be confounded with their failures, for I trusted them in good faith. No one should blame me for having selected them, and visual synchronism, not being encumbered by their names, should not be tainted by their follies. It appeals confidently to science and practical knowledge for success."

Whatever may be the meaning of this pathetic reference to "my earlier patents," we at least join heartily with Mr. Rogers in his disgust at the "great men" who "conspire to pocket money" out of the devices of the poor but honest inventor, and then leave him "tainted with their follies." 'Tis a sad story, though doubtless only half told.

Signalling by Electric Light in the French Navy.—During the recent manœuvres of the French fleet in the Mediterranean signals were transmitted at night by means of incandescent lamps strung from the yard arms of the vessels, and which were lit up or extinguished by a make-and-break key manipulated from the quarter deck. For the transmission of messages by the Morse code a single lamp is of course sufficient, but naval signals must in many cases be capable of prolonged display. To meet this requirement a row of ten lamps is arranged, and the signals are made by sending current through any one or more lamps. The system was found to give satisfactory results.

THE ETHICS OF OFFICIAL APPOINTMENTS.

Of the many choice additions to English literature that are credited to the pen of Mr. ROBERT LOUIS STEVENSON not the least will be counted the charming little biographical sketch of THOMAS STEVENSON, his father, in this month's *Contemporary Review*. Elsewhere we have reprinted a short extract from the paper relating to that sphere of STEVENSON'S activities, namely, Lighthouse Illumination, more particularly interesting to our readers. But it is interesting also from a point of view which has less to do with his high merits as an inventor than with his high morality as a man. A filial enthusiasm which no one will think at all overstrained impels Mr. R. L. STEVENSON to claim for his father the distinction of being a public benefactor, in that he spent a long life in successfully combating with the difficulties and dangers of coast navigation, and was the means of surrounding the mariner's perilous career with conditions of confidence and safety. Not unnaturally, the comparatively little known work of his father is a distressing fact to the son, and in dwelling upon the magnitude of THOMAS STEVENSON'S services to his country he offers an explanation of the causes which have prevented his father's name being honoured, as it deserves to be, by the outside world—that is to say, by the general public, who, as a rule, are as prodigal in their acknowledgements of such labours as the most exacting spirit can desire. But the general public did not know of these labours; and a loving son, jealous of his father's reputation, supplies us with the reason. His father was a public officer, an expert paid by the Government, and he never took out a patent. Thus it happens that while his inventions are in hundreds of places where the public see them, his name never appears there. Mr. R. L. STEVENSON makes no complaint on this account, merely insisting on the credit where there has been failure to record it; but he does incidentally observe that whereas the patentee of perhaps some insignificant improvement gets blazoned all over the world, the self-denying and incessant devotion of a whole life may pass away unnamed and unacknowledged if the man, as in the case of THOMAS STEVENSON, besides being a hardworking public servant, happens to be too conscientious to establish his claims through the Patent Office.

Mr. STEVENSON affirms this not only of his father but of the family of the STEVENSONS, who, holding Government appointments, regarded their original work as something due already to the nation, and none of them has ever taken out a patent. We wish that the example of this famous band of workers were more generally followed, and that the morbid sensitiveness of conscience with which the son tells us his father was afflicted were a little more common than it actually is. THOMAS appears to have had some qualms even in respect to the mathematical help he had sometimes to obtain from friends in working out formulæ that were beyond his ken. Seemingly, he half reproached himself for receiving pay in respect to work every scrap of which he had not done with his own hand or brain. It surprises us, therefore, not at all that such a man never did violence to his ideas of integrity so far as to obtain outside pecuniary reward for work which he had already received payment for performing. The nation paid him a salary, which he accepted in full for his services; to have taken out a patent would, in his estimation, have been to seek to make the nation pay him twice over. This conception of his obligation, we are now reminded by his son, cost him not only the sacrifice of money but of fame, which some men value—and, perhaps, rightly value—more than money. One man may contrive and equip a beacon which shall be the means of saving countless lives to the end of time, but his name may be never remembered; while another man shall hand his own down to posterity for having concocted a new paint with which the beacon is decorated. This is not exactly as it should be. No exception need be taken to the painter's brass label; but if the builder himself is not sufficiently brazen in asserting his identity, his employers should freely and gratefully supply what his modesty withholds. In other words, when public departments enjoy the privilege of possessing a servant who places his whole resources at their disposal, it is their duty at least to see that he suffers nothing by having preferred the public service to his own personal speculations. Fame is worth something as a moral incentive; and as all men are not constituted like the STEVENSONS the Government would be none the less well served, but probably better, if it were as careful to pay attention to the sentimental as to the pecuniary side of its bargain with scientific and ingenious *employés*.

This is the first and obvious suggestion which arises out of the consideration of the late THOMAS STEVENSON'S career. Not every eminent inventor has the good fortune to have a son famous in letters who can write his biography after him; and the employers could very easily supply the deficiency at a trifling cost. Every invention should bear the inventor's name, whether patented or not—especially when not; and if this is true of inventions generally it is especially due to inventors who are public servants and have foregone the rights of patentees. But there are reflections of a more general character, with which Mr. R. L. STEVENSON, of course, has no concern, but which we have long desired to give expression to, and gladly take advantage of the present occasion for discussing. We are not at all satisfied with the ethics of the public service in relation to patented inventions. It seems to us that the STEVENSONS were entirely right in their estimate of public duty; and although we are far from

Digitized by Google

asserting that the opposite course is in all cases morally wrong, we do think that a public department has it in its power to make such cases wholly indefensible, so that the conduct of these Scottish inventors shall not be the exception but the rule. First, as we have already remarked, there should be a frank recognition of the title to posthumous distinction; but, secondly, the remuneration in lifetime should be on a high scale—high enough, that is, to allow of no excuse for coveting the rewards which a patented invention yields outside the public service. These conditions being complied with, we have no hesitation in saying that a public or *quasi*-public servant who takes out a patent for an invention associated in any way with his profession is guilty of an immoral act. Individual cases might still deserve special consideration on their merits; but, broadly speaking, a servant of the public adequately rewarded for his services out of the taxes of the country has no business to tax it afresh at his own assessment.

Does the reader require to be informed that examples of laxity in this respect on the part of public servants are not far to seek? He may find them in almost every public department. In some of these it is hard to say which is most to blame, the inventor for his greed, or his employers for their stinginess; but in others the inventor is flagrantly in the wrong, and has no excuse but for the general laxity of usage which condones his conduct. Heads of the scientific branches of various Government departments are known to have made large sums of money by inventions or discoveries which ought to be, on strict moral principles, the sole property of the several departments, or, what is practically the same thing, the property of the nation, but which have been appropriated by the individuals under the protection of the Patent Laws. Nominal prohibitions notwithstanding, the thing is done with impunity; and, it is only fair to add, sometimes because the department will not recognise as it ought the pecuniary value of an invention, claiming it unfairly at the price of ordinary wages. But sometimes the case comes under a quite different head. Professors are engaged in the cause of public instruction at salaries which are apparently considered to be inadequate. They are supplied at the public expense with costly laboratories and appliances which could never have been at their disposal but for the appointments. Possessed of these exceptional advantages they make discoveries and perfect inventions which nobody else has a chance of rivalling, and for which they straightway take out patents. This may be quite legitimate as arising out of the original bargain. But surely it is absurd to appeal to the public for funds under such conditions as these. If the public subscribe, the public have a right to the untaxed fruits of their liberality; but to this end they must see that the professors are thoroughly well paid. They ought not to be asked to endow a splendid laboratory, for example, in order that Professor X. or Doctor Y. may invent something worth patenting to eke out his salary, and they should take care that he is relieved from that temptation. Not long ago a scheme was mooted for endowing a national institute for Scientific Research. Before such a proposal can be seriously discussed in this country we must have some assurance that the scientists will recognise their own obligations in the matter, and waive all pretence of right to patent what their researching may find. If a healthier moral tone, more akin to that of the renowned STEVENSON family, prevailed among our public scientific men there would be no need to suggest this precautionary condition; but in these days a lofty standard of rectitude is by no means universal in the scientific world, and, we rather suspect, is too generally regarded as a quixotic or morbid eccentricity.

CORRESPONDENCE.

EDWARD DAVY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of 15th April last Mr. Wilson describes an automatic accumulator switch, the diagram of which looks like one devised more than fifty years ago by Edward Davy for a similar purpose. It is figured and described on page 393 of my "History of Electric Telegraphy" (Spon, 1884).

In your leading article of July 7, 1883, you said:—"One cannot help feeling, as we read the highly suggestive notes and confident anticipations with which his (Davy's) memoranda and letters are crowded, that had he remained in England to steer the destinies of the electric telegraph, it would have made more progress than in other hands it actually did make. What he accomplished was clearly the outcome of his own original mind; and what he predicted as possible, but allowed to be fulfilled by somebody else, belongs to him also."

Is Mr. Wilson another of Edward Davy's numerous debtors?

In this the jubilee year of the electric telegraph we ought not to be unmindful of the claims of those who have lived along the line.—Yours, &c., J. J. FAHIE.

Teheran, Persia, May 9, 1887.

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the important discussion which is proceeding in your columns on the framing of estimates for electric lighting, while refraining for the present from expressing any definite views on the subject as a whole, I would fully endorse the opinion of Messrs. Anderson and Munro that electrical engineers should adopt some definite standard of illumination for a given space, and unless otherwise specified it should be understood that all estimates are drawn up on this basis. The following table, which is taken from the results of a large number of installations, principally in France and Germany, might serve as the basis of such a standard:—

INDOOR ILLUMINATION (floor space lit by each 16 candle-power lamp).

Height of lamp. ft.	Space. sq. ft.	Height of lamp. ft.	Space. sq. ft.
6·5	86	13	62
8·2	75	14·5	60
9 8	66	18	58
11·5	64	20	56

Halls, factories, &c., for each 500 candle-power arc about 1,600 square feet may be taken. For markets, railway stations, &c., for each 800 candle-power arc, 5,000 to 6,500 square feet; and for out of door illumination, streets and open spaces, for each 800 candle-power arc 13,000 to 16,000 square feet may be taken.—Yours, &c., PLONMEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last week's issue Messrs. Anderson and Munro, in the latter part of their letter, refer to a subject which I do not consider has anything to do with the matter. However, they might have stated that along with their letter to the General Manager of the North British Railway Company they enclosed a specification, in which the certain sum named amounted to several hundred pounds, and which they stated in their second method was for purchase of accumulators, from which I inferred that the latter were to be used for lighting the carriages. In the contact system which I patented, as already described in your columns, the current is supplied direct to each individual carriage, from a self-regulating dynamo, by means of a centre rail and contact pulleys.

Although 8 trains, or 64 carriages, have been fitted up and are running daily, it has taken six months to do this, as they were only done gradually, as they came from the repair shops, while only one man is employed in the work.

A little consideration would also have shown that the material used is not manufactured by Messrs. Anderson and Munro, as it comprises chiefly contact pulleys of crucible steel,

Digitized by Google

Edison-Swan lamps and holders, white enamel reflectors of malleable iron, and glass globes, &c. Their offer was submitted to me at the time, but I do not seem to have had the knowledge of an intelligent electrical workman, as I could not see how a 4 or 5 compartment carriage, with two lamps in each, could be fitted up in a workmanlike manner, with the necessary wires, lamps, holders, reflectors, globes, &c., for the sum of £4.—Yours, &c., THOMAS CARSWELL, Assistant Engineer, North British Railway.

Edinburgh, June 8th, 1887.

REGULATION OF SERIES TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The interesting notices of Messrs. Sharp and Kent's regulation of series transformers do not contain any actual practical results of careful tests to ascertain the losses in the "choking coils." The figures in the fifth column are calculated from C^2R, which is not applicable in the case of a choking coil. These figures obtained thus are no doubt nearly correct, and the difference between these figures and the correct figures may be too small for consideration when only one coil is employed; but in a distribution system where perhaps 1,000 coils might be in use a small difference in each becomes a large difference on the whole number, and would materially affect the economy.

The opposition to the current which a rapidly alternating E.M.F. tends to send through a choking coil is made up of three factors:—

First. Ohmic resistance.

Second. Apparent resistance, due to rapidity of alternations preventing the current from reaching a steady value distribution over the section of the conductor. This apparent resistance is the same for a wire wound into a coil, laid out straight, or bent back on itself.

Third. "Impedence" due to self-induction, or, rather, the induction of the convolutions of the coils of wire on each other, the value of which depends on the shape of the coil and also on the form, size, and quality of the core of iron upon which choking coils are always wound.

This core in all coils becomes hot, proving that currents are generated in it. By excessive lamination or subdivision this heating can be reduced to a minimum; but still it is always there, and the energy expended in heating this core cannot be found, and is not accounted for by the C^2R formula.

In a transformer $C^2R + C_s^2R_s$ gives the energy expended in the transformer conductors and secondary circuit, where C is primary current and R primary ohmic resistance, C_s secondary current and R_s secondary resistance, including lamps, lead, &c.; but to find the total energy expended we must find the energy expended in the core in addition to the above. We cannot measure the C and R in the core, but we can measure the energy expended in it by measuring the heat generated per minute or hour in it. In an actual test of this kind, with a pressure of 1,200 volts, a resistance in the coil of 5 ohms, a current of 0·18 ampere was found, while the total energy measured in heat was equivalent to over 270 watts, a figure agreeing neither with C^2R nor $E \times C$. A similar result was published by Messrs. Zipernowski and Co., who found nearly 400 watts expended in a resistance under 5 ohms with a current of 0·17 amp., the pressure being over 1,900 volts.

Until we get methods of measuring alternating pressures and currents, calculations like the tables given are not to be taken as anything but approximations.

Mr. Elihu Thomson and Messrs. Sharp and Kent may refer to a patent of Dr. Hopkinson, dated 1881, No. 3362, and to various works by Gordon for early applications of choking coils in place of resistances and in place of lamps.

I referred to Dr. Hopkinson's coils in a letter to the *Electrical Review* of 1883, and mentioned their great value as not absorbing energy like ordinary resistances. Sir William Thomson pointed out their value to me as regulators early in that year, and instanced Dr. Hopkinson's work in a conversation which I had the honour to be present at, the subject being induction coils and self-induction.

Lastly, I may be permitted to express an opinion that to say a transformer is *series wound* is somewhat unmeaning; all transformers known to me are wound alike, whether placed in series order or parallel order in the main supply conductors. The difference between a series transformer and a parallel transformer lies in the section and length of the wires, not in the winding. In a parallel transformer the primary wire is always longer and thinner than the secondary; the same may be the case in a series transformer, but oftener the reverse will be found to be the case. Series transformer or parallel transformer is better; or current transformer and potential transformer might do.—Yours, &c., RANKIN KENNEDY.

THE LIGHTING OF TURIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I must ask you to allow me to trespass upon your valuable space, as Mr. J.W. Lieb's letter in your issue of the 3rd inst. is calculated still further to mislead.

The real facts connected with the Turin installation will be found in the accompanying translation of a letter addressed by Mr. Gaulard to the Syndic of Turin at the moment when the circumstances referred to by Mr. Lieb occurred.—Yours, &c.,

T. E. PICKERING, secretary.

(*Translation.*)

To the Syndic of Turin.

Turin, 28th January, 1887.

Sir: The letter you did me the honour to write me on the 27th January infers that the municipal commission would wish to hold the National Company responsible for the defects in the cable laid by Messrs. Bellani Bros, or for the accidents that might happen to that cable during the working of the apparatus.

I did not believe that such an opinion could be expressed by the commission after the conference I had the honour to have with its members on Monday, the 17th inst, but as it is otherwise I will reply by stating, firstly, that the contract with Messrs. Bellani Brothers stipulates our right of absolute control over the installation carried out by them, and consequently the power to reject any defective portion of the installation. I will add further that, in the present instance, I challenge all electricians to justify the possibility of altering any cable by the fact of cutting out of circuit one or several apparatus fed in derivation by this cable. Be this as it may, I think it indispensable to recall here the respective positions of the Turin municipality and Messrs. Gaulard and Gibbs, with the mutual obligations resulting therefrom.

In 1884 the Italian Government set a great example to the other European nations by initiating the institution of an international competition for the greatest advance realised in the transport of electrical energy over a long distance, and at the instigation of its capable and esteemed syndic, the Count de Sambuy, the City of Turin was associated in the scheme.

The success of the experiments made between Turin and Lanse by means of the Gaulard and Gibbs secondary generators has given to the city of Turin an important place in the history of industrial science.

Following upon these facts, the Count de Sambuy, by his powerful and kindly assistance, obtained from the Municipal Council their decision to employ the Gaulard-Gibbs system for the electric lighting of a part of the city of Turin.

To realise the wishes of the Municipal Council, Messrs. Gaulard and Gibbs were obliged to grant the right to represent them in Italy to capatilists to act as their substitutes as regards the municipality of Turin. At the present time, however, Messrs. Bellani Bros, instead of defending the interests of Messrs. Gaulard and Gibbs, have opposed them by supporting infringers, substituting Zipernowski, Déri, and Blathy apparatus for those of Messrs. Gaulard and Gibbs, under the pretext that the apparatus of the latter are imperfect. Under these circumstances I have requested the syndic to be good enough to instruct the Municipal Commission to verify the perfect working condition of my apparatus, insisting on this point—that the working may be verified on the spot, and without using the underground cable. I took this step in the loyal intention of relieving the municipality of all responsibility in the legal proceedings which we must necessarily take against Messrs. Bellani, but the municipality cannot lose sight of the moral and material

Digitized by Google

prejudice it would cause to the Gaulard-Gibbs system by not ordering this verification, and the consequent heavy responsibility to which it would be rendered liable.—Yours, &c.,

(Signed) L. Gaulard.

[Now that both sides have placed their version of the facts on record, we think that this correspondence should close.—Ed. *E.*]

MAGNETISM AND GRAVITATION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: My attention has been called to the *Chemical News* of June 3, which contains a paper read by Prof. Crookes at the meeting of the Royal Society, on June 1.

In his paper Mr. Crookes criticised a paper published in the *Scientific Journal* of Dax, by M. Thore, and attempted to explain, but ineffectually as he admits, the rotations of M. Thore's cylinders as owing to the influence of radiant heat.

As I have been conducting a series of experiments during the last 18 months of a somewhat similar character, and have rotated a copper and other spheres under the influence of a single magnetic pole, I shall be obliged by your finding me space in *The Electrician* for the publication of my experiments; more especially as I found that when a copper sphere was suspended and acted upon by a magnetic pole *the approach of the human body alone* was productive of a certain degree of axial rotation in the suspended sphere.

At the recent *conversazione* of the Royal Society, held on May 11th, I exhibited the axial rotation of a copper sphere as described above, but without showing the influence which the human body exerted upon the movements.

I believe this and similar experiments which prove the cause of the rotation sweep away the theory that magnetism is nothing more than a definite molecular polarisation, and demonstrate the existence of a current force, for without such a force the slow continuous rotation of the sphere could not be obtained.

I obtained the phenomenon of the rotation of the sphere as described above by a careful study of magnetism which I was induced to make owing to some physiological investigations in which I had been engaged for many years past into the nature of the force by which animal life is sustained.

For instance, I arrived at the conclusion that some physical differences existed between the arterial and venous states of the blood, which, if their full significance could be detected, would prove the nature of the vital force.

Having regard to the presence of iron in the blood of almost all animals, and to the important office it appears to fulfil, I was led to investigate the magnetic differences of the arterial and venous blood. I then proved experimentally* that the arterial blood is paramagnetic to the same blood in the venous state. But I had no sooner completed these investigations than I found they would be of little service unless the character of the magnetic force could be more clearly defined than it then was; I therefore continued my researches by making a careful investigation into the nature of magnetism.

My first experiments were conducted upon bar magnets, and I then established the fact that the equator and axis of a bar-magnet are always oblique.† This led to the inference that the same cause for obliquity existed in the bars as in terrestrial magnetism.

By a second series of experiments on bar magnets, on which a paper was read at the Physical Society of London, and subsequently published in *The Electrician*, the seat of polarity near the end of a bar magnet was found to change when two poles of the same sign were placed together, and to move to the line of contact.

My more recent investigations have been into the nature and cause of terrestrial magnetism, and I believe I have now determined the relations which subsist between magnetic force and gravitation, and further, I am able to prove that the motion of the celestial bodies, as well as the movements which germinal matter undergoes in the process of being converted into animal or vegetable cells, are equally under the influence of this force; and that the character of their motions, of their axial inclination, and of their orbits is determined by the description of resistance which the material unit, whether large or small, offers to the all-pervading current force.—Yours, &c.,

Reading, June 9th, 1887. Richard C. Shettle.

NATURALISTS AND THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Having just noticed in your influential journal of this week a paragraph of the visit of the Liverpool Biological Marine Association to the Menai Straits, I notice that you have credited Messrs. Siemens with the electrical work on board the L. S. A. ss. "Hyenæ," which was lent to them to convey the members to their destination—viz., Puffin Island. The reason for my writing you thus is to mention the fact of our fitting out the boat last autumn for the association, and perhaps it might interest you to have a few particulars of the installation. The dynamo is a "Phœnix" compound-wound E.M.F. 60-volt, C. 70 amperes, and is driven direct from the grooved fly-wheel of a Gwynne engine with a six ply cotton rope, there being four separate circuits from the machine, one for thirty 20 candle-power incandescent lamps (Edison-Swan), and one circuit each to two 3,000 candle-power Pilsen arc lamps, which are fitted with special lanterns and provided with suitable gearing for raising and lowering them from the fore and main masts. The other circuit consists of four 100 candle-power incandescent Edison-Swan lamps, in specially designed submarine lanterns, with insulated twin cable of 240 strands to obtain great flexibility, which pays out while the diver is descending with the light from a revolving drum. The switch-board has been especially designed by us to meet the requirements of a vessel engaged in salvage operations. I may add that the whole of this work has given great satisfaction to the owners, as the steamer has been busily engaged on several large ships which have been wrecked in the vicinity of the Mersey, and the electric light having proved of immense advantage in enabling the work of salving the cargo to be carried on at night as well as by day. I omitted to mention above that by means of suitable resistances on the switch-board it is possible to run either the whole of the incandescent and arc lamps at once, or by switching off the arc lamps to run only the incandescent, or *vice versâ*.

I merely mention this as there has been hitherto some difference of opinion as to the practical and successful working of arc and incandescent lamps from one machine, there being no perceptible difference in any of the lamps that are lighted, should one or more of the circuits be switched off, the speed of the machine, of course, remaining constant at 1,000 revolutions. I should like to bring before your notice that having been personally engaged in some fishing experiments by the electric light in the Menai Straits this winter, whenever we had occasion to lower the submarine lamp to the bottom of the river the raising of the lamp was invariably accompanied by shoals of fish.

Trusting that I have not encroached upon your valuable space, and feeling sure you will be kind enough to correct the statement which has appeared in this week's number in your next issue, if convenient.—Yours, &c.,

F. Hanson Perry.

F. H. Perry and Co., Limited, 36, Victoria-street, Liverpool, June 7th, 1887.

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis:—

ON THE MIGRATION OF IONS AND AN EXPERIMENTAL DETERMINATION OF ABSOLUTE IONIC VELOCITY.

BY DR. OLIVER LODGE.

(Concluded from page 62.)

Experiments on travel of both Ba *and* Cl *through jelly tubes.*

Four fresh tubes, numbered XII.–XV., each 40 centims. long, and more simply bent, were filled with the following jelly, containing sulphate of silver as a test for the presence both of Ba and of Cl. The jelly was made

by taking 40 cc. of the previous acetic acid gelatine and adding to it 10 cc. of the following solution—viz., 20 cc. of nitrate of silver sol. ($AgNO_3$ in 50 cc.) + 2 cc. sulphuric acid (H_2SO_4 in 10 cc.) + 78 cc. of water. Tube XIV. was ·562 centim. in diameter; the others were not measured. The tubes were arranged thus:—

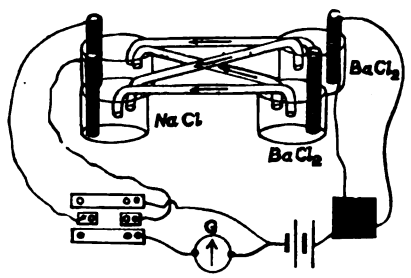

Fig. 8.

so that the current through any one of them could be measured. The anode vessels contained $BaCl_2$, the cathode vessels NaCl.

The E.M.F. of the applied battery was measured by an Ayrton and Perry voltmeter as 29 volts. (*See* Table A.)

Late on February 24 the current was stopped because the advancing ions had nearly met, and it was desired to observe whatever phenomenon might accompany their meeting. The tubes were left in position for a day or two, and by February 27 it was found that, while the precipitation boundaries due to the current still remained, three other fainter outlines had made their appearance, one, a fresh one, crawling along from the $BaCl_2$ end, the other two advancing beyond the current—formed precipitate. The three are labelled in the table *a*, *b*, *c* respectively, and their positions are indicated; but no meaning is attached to them.

The result of these experiments is to give a rough absolute determination of the rates of travel of Ba and of Cl through the jelly, and to show that the speed of Cl is pretty exactly twice that of Ba. Now, can this be assumed to be probably due to the fact that barium is a dyad, while chlorine is a monad? or is it due to the fact that the atomic weight of Ba, 137, is almost twice that of Cl_2—viz, 71? The simplest mode of examining this question is to replace the chlorine by bromine or iodine, whose atomic weight is quite different.

Similar experiments with iodine instead of chlorine.

The cathode vessels were filled with a solution of potassic iodide instead of the sodic chloride solution. An E.M.F. of 29 volts was again applied to the same four tubes, filled with the same jelly as before, and the results are subjoined. The precipitation on the advancing iodine side was, however, double; one faint outline in advance, which it was suspected might be due to a trace of chlorine impurity in the KI, and the main precipitation, which was considered to be real AgI. Successive positions of the faint advance cloudiness are recorded in the following table in parentheses. (*See* Table B.)

The cathode vessel was filled with a solution of potassic bromide containing 30 grammes of salt to 300 grammes of water. Tubes filled with same Ag_2SO_4 gelatine as before, each 40 centimetres long. (*See* Table C.)

As in the iodine experiments there was an advance cloudiness, faint but well defined, in advance of the main precipitate. The readings of the position of this are specified in the above table in parenthesis. The

meaning of it was not certainly made out, but it was provisionally set down as due to impurity.

Combined experiments on several substances.

It thus appears that Cl, Br, and I all go at about the same rate and about twice as quick as Ba. It remained to see what strontium and calcium did. Calcium is not an easy substance to experiment on; its sulphate is too soluble. But strontium is sufficiently easy, though not so sharp and well defined as the barium. To make a better comparison six tubes were taken, each 40 centimetres long, filled with the same Ag_2So_4 gelatine solution as before, and arranged in multiple arc with the same E.M.F. (about 40 volts) applied to all of them. This is the E.M.F. between the electrodes, and since gas is given off at the carbon electrodes something like three volts must be deducted for polarisation and for resistance of liquid in vessel. But it was not thought probable that absolute results could be of much use when the composition of jelly is so vaguely known. The diameter of tube XIX. was ·370 centim.

The six tubes were arranged as in Fig. 9; the two anode vessels being filled, one with $BaCl_2$, the other with $SrCl_2$, and the three anode vessels with NaCl, KBr, and KI, respectively; in each case 10 grammes of salt and 100 cc. of water. (*See* Table D.)

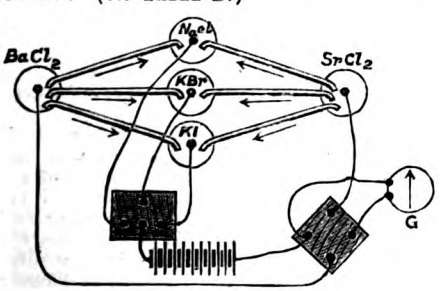

Fig. 9.

Determination of the resistance of the jelly-filled tube.

July 1.—One of the 40-centimetre tubes filled with plain gelatine gave 67,720 ohms resistance. The same tube had the jelly melted out, the tube cleared and filled with dilute acetic acid (centigramme molecule in 5 cc.), and its resistance was now 160,000.

Another determination, by Mance's method, gave for the acetic acid filled tube 142,000 ohms, at 21°C; for the jelly-filled tube at 19·5, 78,000 ohms; and for the same tube filled with dilute sulphuric acid (H_2SO_4 in 10 cc.) 730 ohms.

This jelly tube was then left to stand all night with its feet in dilute acetic acid. By the morning its resistance had increased, as the acid soaked up into it, to 84,000 ohms.

Improved experiments on the velocity of ions in free liquid.

Any siphon tube arrangement joining two open vessels cannot be free from difficulties caused by electric endosmose, whatever precautions be adopted. Hence a series of experiments were planned with one of the vessels closed and completely full, so that no more or less could be driven into or out of it, either by the action of the current or by changes of level, except such calculable changes as result from alteration of volume of electrode or solution near it, or from changes of temperature. To this end the cathode vessel was made of the shape shown in Fig. 10, and the experimental tube fitted to it by a ground joint. It was necessary to avoid evolution of gas, so the cathode vessel was filled with saturated sulphate of copper solution, and it was immersed in a constant-temperature water-bath. The tube was 40·7 centimetres long, and it was filled with dilute HCl (1 centigramme molecule in 5 cc.). The anode vessel contained a solution of baric chloride (10 grammes salt to 100 of water) and a carbon electrode.

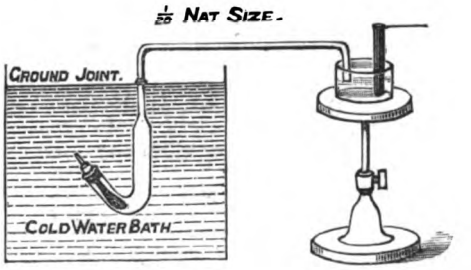

Fig. 10.

August 7.—The cathode vessel having been in the bath all night, and the temperature being 16·2°, the tube was put in at x. hrs 20 min., and the current started at x hrs. 48 min. with a difference of potential of 51·3 volts between the electrodes. A silver voltameter was included in the circuit.

By xxii. o'clock there was no ring formed in the tube, but in the bend near the cathode end of the tube there was a slight deposit. The temperature of the bath was still 16·2°. It was afterwards found that the silver plate of the voltameter had dissolved, and thereby broken contact.

Digitized by Google

August 9.—Another precisely similar experiment; except that a galvanometer was used instead of a voltameter. Current started at xii. hrs. 15 min. with E.M.F. 50 6 volts. The galvanometer readings fell gradually from 6·7° to 3·8°. At xvi. hrs. 40 min. a disc of precipitate was found in the tube, the volts being now 49 7. The thickness of the disc was ·17, and the positions of its two faces were 3·79 and 3·96 centims. from the cathode end of the tube. Result sketched here.

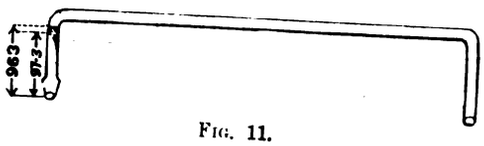

FIG. 11.

Summary of the experiment.

Time taken for ring to first form estimated at 4 hours.
Distance travelled by Ba 36 9 centims. $= b + x$.
" " SO_4 3·96 centims. $= a - x$.
Average difference of potential between electrodes, 50·15 volts.
Length of tube, 40·7 cm.
Current from 5 to 2·7 milliamperes.

The x in the above relates to a possible contraction of the contents of cathode vessel, to be determined later.

August 10.—Another similar experiment with same tube. Result sketched in Fig. 12.

Time taken for ring to form, 8 hours.
Distance travelled by Ba 37·3.
" " SO_4 3 55.
Difference of potential, 48·4.
Current from 4 to 1·5 milliamperes.

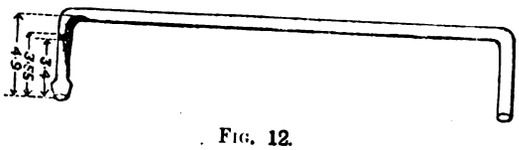

FIG. 12.

Blank experiment with no current on, to see the effect of diffusion.

August 12.—Tube connected at x. 30. No ring formed, but by August 17, xiv. 30, a slight precipitate was forming in the centre of the tube, *i.e*, after 5 days 4 hours.

(*To be continued.*)

NOVEL PHENOMENA OF ALTERNATING CURRENTS.

At the annual meeting of the American Institute of Electrical Engineers, held at New York, the following paper was read by Prof. ELIHU THOMSON:—

The actions produced and producible by the agency of alternating currents of considerable energy are assuming greater importance in the electric arts. I mean, of course, by the term alternating currents, currents of electricity reversed at frequent intervals, so that a positive flow is succeeded by a negative flow, and that again by a positive flow, such reversals occurring many times in a second, so that the curve of current or of electromotive force will, if plotted, be a wave line the amplitude of which is the arithmetical sum of the positive and negative maxima of current or electromotive force, as the case may be, while a horizontal middle line joins the zero points of current or electromotive force.

It is well known that such a current passing in a coil or conductor laid parallel with, or in inductive relation to a second coil or conductor, will induce in the second conductor, if on open circuit, alternating electromotive forces, and that if its terminals be closed or joined, alternating currents of the same rhythm, period, or pitch will circulate in the second conductor. This is the action occurring in any induction coil whose primary wire is traversed by alternating currents, and whose secondary wire is closed either upon itself directly or through a resistance. What I desire to draw attention to in the present paper are the mechanical actions of attraction and repulsion which will be exhibited between the two conductors, and the novel results which may be obtained by modifications in the relative dispositions of the two conductors.

In 1884, while preparing for the International Electrical Exhibition at Philadelphia, we had occasion to construct a large electro-magnet, the cores of which were about 6in. in diameter and about 20in. long. They were made of bundles of iron rod of about ⅝in. diameter. When complete the magnet was energised by the current of a dynamo giving continuous currents, and it exhibited the usual powerful magnetic effects. It was found also that a disc of sheet copper, of about ⅛in. thickness and 10in. in diameter, if dropped flat against a pole of the magnet, would settle down softly upon it, being retarded by the development of currents in the disc due to its movement in a strong magnetic field, and which currents were of opposite direction to those in the coils of the magnet. In fact, it was impossible to strike the magnet pole a sharp blow with the disc even when the attempt was made by holding one edge of the disc in the hand and bringing it down forcibly towards the magnet. In attempting to raise the disc quickly off the pole a similar but opposite action of resistance to movement took place, showing the development of currents in the same direction to those in the coils of the magnet, and which currents, of course, would cause attraction as a result.

The experiment was, however, varied, as in Fig. 1. The disc D was held over the magnet pole, as shown, and the current in the magnet coils cut off by shunting them. There was felt an attraction of the disc or a dip towards the pole. The current was then put on by opening the shunting switch, and a repulsive action or lift of the disc was felt. The actions just described are what would be expected in such a case, for when attraction took place currents had been induced in the disc D in the same direction as those in the magnet coils beneath it, and when repulsion took place the induced current in the disc was of opposite character or direction to that in the coils.

Now let us imagine the current in the magnet coils to be not only cut off, but reversed back and forth. For the reasons just given we will find that the disc D is attracted and repelled alternately; for whenever the currents induced in it are of the same direction with those in the inducing or magnet coil, attraction will ensue, and when they are opposite in direction repulsion will be produced. Moreover, the repulsion will be produced when the current in the magnet coil is rising to a maximum in either direction, and attraction will be the result when the current of either direction is falling to zero, since in the former case opposite currents are induced in the disc D in accordance with well known laws, and in the latter case currents of the same direction will exist in the disc D and the magnet coil. The disc might of course be replaced by a ring of copper or other good conductor, or by a closed coil of bare or insulated wire, or by a series of discs, rings, or coils superposed, and the results would be the same. Thus far, indeed, we have nothing of a particularly novel character, and doubtless other experimenters have made very similar experiments and noted similar results to those described.

The account just given of the effects produced by alternating currents, while true, is not the whole truth, and just here we may supplement it by the following statements:—

An alternating current circuit or coil repels and attracts a closed circuit or coil placed in direct or magnetic inductive relation therewith; but the repulsive effect is in excess of the attractive effect.

When the closed circuit or coil is so placed, and is of such low resistance metal that a comparatively large current can circulate as an induced current, so as to be subject to a large self-induction, the repulsive far exceeds the attractive effort.

For want of a better name I shall call this excess of repulsive effect the "electro-inductive repulsion" of the coils or circuits.

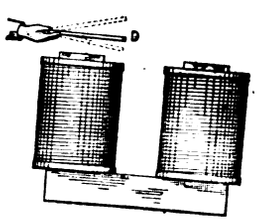

FIG. 1.

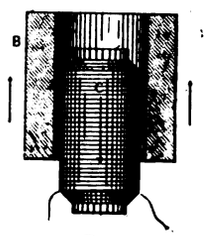

FIG. 2.

This preponderating repulsive effect may be utilised or may show its presence by producing movement or pressure in a given direction, by producing angular deflection as of a pivoted body, or by producing continuous rotation with a properly organised structure. Some of the simple devices realising the conditions I will now describe.

In Fig. 2 C is a coil traversed by alternating currents, B is a copper case or tube surrounding it, but not exactly over its centre. The copper tube B is fairly massive and is the seat of heavy induced currents. There is a preponderance of repulsive action tending to force the two conductors apart in an axial line. The part B may be replaced by concentric tubes slid one in the other, or by a pile of flat rings, or by a closed coil of coarse or fine wire insulated, or not. If the coil C, or primary coil, is provided with an iron core such as a bundle of fine iron wires, the effects are greatly increased in intensity and the repulsion with a strong primary current may become quite vigorous, many pounds of thrust being producible by apparatus of quite moderate size.

The forms and relations of the two parts C and B may be greatly modified with the general result of a preponderence of repulsive action when the alternating currents circulate.

Fig. 3 shows the part B of an internally tapered or coned form, and C of an externally coned form, wound on an iron wire bundle, I. The action in Fig. 2 may be said to be analagous to that of a plain solenoid with its core, except that repulsion, and not attraction, is produced, while that of Fig. 3 is more like the action of tapered or conically wound solenoids and taper cores. Of course it is unnecessary that both be tapered. The effect of such shaping is simply to modify the range of action and the amount of repulsive effort existing at different parts of the range.

In Fig. 4 the arrangement is modified so that the coil C is outside, and the closed band or circuit B inside and around the core I. Electro-inductive repulsion is produced as before.

It will be evident that the repulsive actions will not be mechanically manifested by axial movement or effort, when the electrical middles of the coils or circuits are co-incident. In cylindrical coils in which the current is uniformly distributed through all the parts of the conductor section, what I here term the electrical middle, or the centre of gravity of the ampere turns of the coils, will be the plane at right angles to its axis at its middle, that of B and C in Fig. 4 being indicated by a dotted line. To

Digitized by Google

repeat, then, when the centres or centre planes of the conductors, Fig. 4, coincide, no indication of electro-inductive repulsion is given, because it is mutually balanced in all directions; but when the coils are displaced a repulsion is manifested, which reaches a maximum at a position depending on the peculiarities of proportion and distribution of current at any time in the two circuits or conductors.

It is not my purpose now to discuss the ways of determining the distribution of currents and mechanical effects, as that would extend the present paper much beyond its intended limit. The forms and relative arrangement of the two conductors may be greatly varied. In Fig. 5 the parts are of equal diameter, one, B, being a closed ring, and the other, C, being an annular coil placed parallel thereto, and an iron core or wire bundle placed in the common axis of the two coils increases the repulsive action. B may be simply a disc or plate of any form, without greatly affecting the nature of the action produced. It may also be composed of a pile of copper washers or a coil of wire, as before indicated.

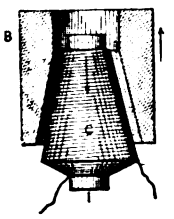

Fig. 3.

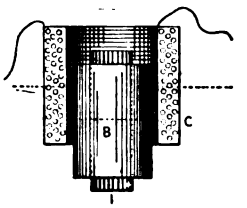

Fig. 4.

An arrangement of parts somewhat analogous to that of a horseshoe electro-magnet and armature is shown in Fig. 6. The alternating current coils C C′ are wound upon an iron wire bundle bent into U-form, and opposite its poles is placed a pair of thick copper discs, B B′, which are attracted and repelled, but with an excess of repulsion depending on their form, thickness, &c.

If the iron core takes the form of that shown by I I, Fig. 7, such as a cut ring with the coil C wound thereon, the insertion of a heavy copper plate B into the slot or divided portion of the ring will be opposed by a repulsive effort when alternating currents pass in C. This was the first form of device in which I noticed the phenomenon of repulsive preponderance in question. The tendency is to thrust the plate B out of the slot in the ring, excepting only when its centre is coincident with the magnetic axis joining the poles of the ring between which B is placed.

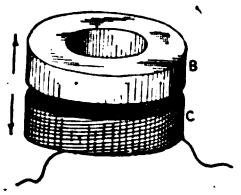

Fig. 5.

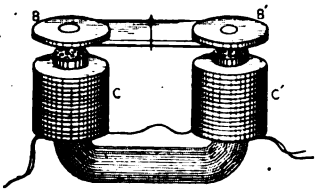

Fig. 6.

If the axes of the conductors, Fig. 5, are not coincident but displaced, as in Fig. 8, then, besides a simple repulsion apart, there is a lateral component or tendency as indicated by the arrows. Akin to this is the experiment illustrated in Fig. 9. Here the closed conductor B is placed with its plane at right angles to that of C, wound on a wire bundle. The part B tends to move towards the centre of the coil C, so that its axis will be in the middle plane of C, transverse to the core, as indicated by the dotted line. This leads us at once to another class of actions, *i.e.*, deflective actions.

When one of the conductors, as B, Fig. 10, composed of a disc, or, better, of a pile of thin copper discs, or of a closed coil of wire, is mounted on an axis X transverse to the axis of coil C, through which coil the alternating

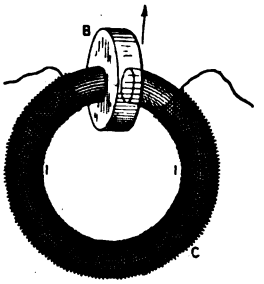

Fig. 7.

current passes, a deflection of B to the position indicated by dotted lines will take place, unless the plane of B is at the start exactly coincident with that of C. If slightly inclined at the start, deflection will be caused as stated. It matters not whether the coil C encloses the part B or be enclosed by it, or whether the coil C be pivoted and B fixed, or both be pivoted. In Fig. 11 the coil C surrounds an iron wire core and B is pivoted above it, as shown. It is deflected, as before, to the position indicated in dotted lines.

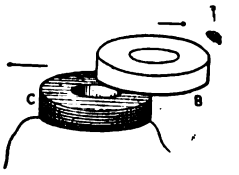

Fig. 8.

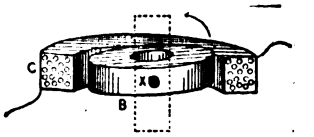

Fig. 10

It is important to remark here that, in cases where deflection is to be obtained, as in Figs. 10 and 11, B had best be made of a pile of thin washers or a closed coil of insulated wire instead of a solid ring. This avoids the lessening of effect which would come from the induction of currents in the ring B in other directions than parallel to its circumference.

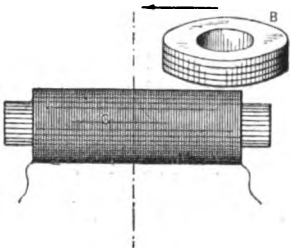

Fig. 9.

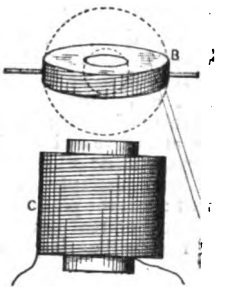

Fig. 11.

We will now turn our attention to the explanation of the actions exhibited, and afterwards refer to their possible applications. It may be stated as certainly true that were the induced currents in the closed conductor unaffected by any self-induction, the only phenomena exhibited would be alternate equal attractions and repulsions, because currents

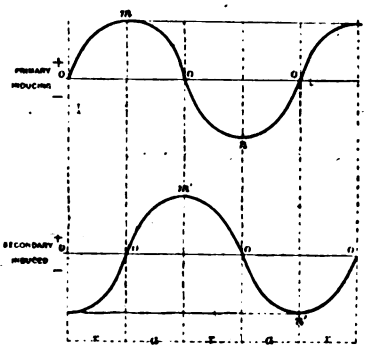

Fig. 12.

would be induced in opposite directions to that of the primary current when the latter current was changing from zero to maximum positive or negative current, so producing repulsion; and would be induced in the same direction when changing from maximum positive or negative value to zero, so producing attraction.

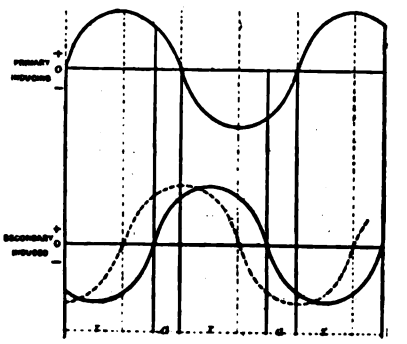

Fig. 13.

This condition can be illustrated by a diagram, Fig. 12. Here the lines of zero current are the horizontal straight lines. The wavy lines represent the variations of current strength in each conductor, the current in one direction being indicated by that portion of the curve above the zero line, and in the other direction by that portion below it. The

Digitized by Google

vertical dotted lines simply mark off corresponding portions of phase or succession of times.

Here it will be seen that in the positive primary current descending from m, its maximum, to the zero line, the secondary current has risen from its zero to m^1, its maximum. Attraction will therefore ensue, for the currents are in the same direction in the two conductors. When the primary current increases from zero to its negative maximum n, the positive current in the secondary closed circuit will be decreasing from m^1, its positive maximum, to zero; but, as the currents are in opposite directions, repulsion will occur. These actions of attraction and repulsion will be reproduced continually, there being a repulsion, then an attraction, then a repulsion, and again an attraction, during one complete wave of the primary current. The letters r, a, at the foot of the diagram, Fig. 12, indicate this succession.

In reality, however, the effects of self-induction in causing a lag, shift, or retardation of phase in the secondary current, will considerably modify the results, and especially so when the secondary conductor is constructed so as to give to such self-induction a large value. In other words, the maxima of the primary or inducing current will no longer be found coincident with the zero points of the secondary currents. The effect will be the same as if the line representing the wave of the secondary current in Fig. 12 had been shifted forward to a greater or less extent. This is indicated in diagram, Fig. 13. It gives, doubtless, an exaggerated view of the action, though from the effects of repulsion which I have produced I should say it is by no means an unrealisable condition.

It will be noticed that the period during which the currents are opposite, and during which repulsion can take place, is lengthened at the expense of the period during which the currents are in the same direction for attractive action. These differing periods are marked r, a, &c., or the period during which repulsion exists is from the zero of the primary or inducing current to the succeeding zero of the secondary or induced current; and the period during which attraction exists is from the zero of the induced current to the zero of inducing current.

But far more important still in giving prominence to the repulsive effect

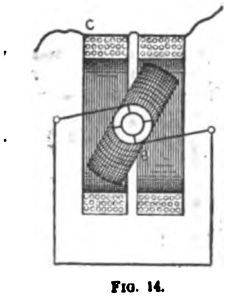

FIG. 14.

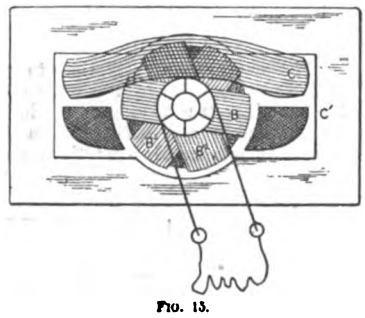

FIG. 15.

than this difference of effective period, is the fact that during the period of repulsion both the inducing and induced currents have their greatest values, while during the period of attraction the currents are of small amounts comparatively. This condition may be otherwise expressed by saying that the period during which repulsion occurs includes all the maxima of current, while the period of attraction includes no maxima. There is then a repulsion due to the summative effects of strong opposite currents for a lengthened period, against an attraction due to the summative effects of weak currents of the same direction during a shortened period, the resultant effect being a greatly preponderating repulsion.

It is now not difficult to understand all the actions before described as obtained with the varied relations of coils, magnetic fields, and closed circuits. It will be easily understood, also, that an alternating magnetic field is in all respects the same as an alternating current coil in producing repulsion on the closed conductor, because the repulsions between the two conductors are the result of magnetic repulsions arising from opposing fields produced by the coils when the currents are of opposite directions in them.

Thus far I have applied the repulsive action described in the construction of alternating current indicators, alternating current arc lamps, regulating devices for alternating currents, and to rotary motors for such currents. For current indicators a pivoted or suspended copper band or ring composed of thin washers piled together and insulated from one another and made to carry a pointer or index, has been placed in the axis of a coil conveying alternating currents whose amount or potential is to be indicated. Gravity or a spring is used to bring the index to the zero of a divided scale, at which time the plane of the copper ring or band makes an angle of, say, 15 degrees to 20 degrees with the plane of the coil. This angle is increased by deflection more or less great, according to the current traversing the coil. The instrument can be calibrated for set conditions of use. Time would not permit of a full description of these arrangements as made up to the present.

In arc lamps the magnet for forming the arc can be composed of a closed conductor, a coil for the passage of current, and an iron wire core. The repulsive action upon the closed conductor lifts and regulates the carbons in much the same manner that electro-magnets do when continuous currents are used. The electro-inductive repulsive action has also been applied to regulating devices for alternating currents, with the details of which I cannot now deal.

For the construction of an alternating current motor which can be started from a state of rest the principle has also been applied, and it may here be remarked that a number of designs of such motors is practicable.

One of the simplest is as follows:—The coils C (Fig. 14) are traversed by an alternating current, and are placed over a coil, B, mounted upon a horizontal axis, transverse to the axis of the coil C. The terminals of the coil B, which is wound with insulated wire, are carried to a commutator, the brushes being connected by a wire, as indicated. The commutator is so constructed as to keep the coil B on short circuit from the position of coincidence with the plane of C, to the position where the plane of B is at right angles to that of C; and to keep the coil B open circuited from the right angled position or thereabouts to the position of parallel or coincident planes. The deflective repulsion exhibited by B will, when its circuit is completed by the commutator and brushes, as described, act to place its plane at right angles to that of C, but being then open-circuited its momentum carries it to the position just past parallelism, at which moment it is again short-circuited, and so on. It is capable of very rapid rotation, but its energy is small. I have, however, extended the principle to the construction of more complete apparatus. One form has its revolving portion or armature composed of a number of sheet iron discs wound as usual with three coils crossing near the shaft. The commuator is arranged to short-circuit each of these coils in succession, and twice in a revolution, and for a period of 90 degrees of rotation each. The field coils surround the armature and there is a laminated iron field structure completing the magnetic circuit. I may say here that surrounding the armature of a dynamo by the field coils, though very recently put forth as a new departure, was described in various Thomson-Houston patents, and to a certain extent all Thomson-Houston machines embody this feature.

Figs. 15 and 16 will give an idea of the construction of the motor referred to. C C^1 are the field coils or inducing coils which alone are put

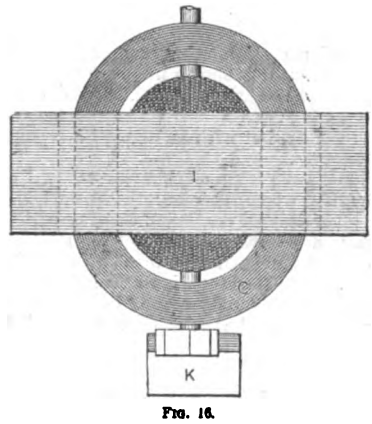

FIG. 16.

into the alternating current circuit. I I is a mass of laminated iron, in the interior of which the armature revolves, with its three coils B, B^2, B^3 wound on a core of sheet iron discs. The commutator short-circuits the armature coils in succession in the proper positions to utilise the repulsive effect set up by the currents which are induced in them by the alternations in the field coils. The motor has no dead point and will start from a state of rest and give out considerable power, but with what economy is not yet known.

A curious property of the machine is that at a certain speed, depending on the rapidity of the alternations in the coil C, a continuous current passes from one commutator brush to the other, and it will energise electro-magnets and perform other actions of direct currents. Here we have, then, a means of inducing direct currents from alternating currents. To control the speed and keep it at that required for the purpose, we have only to properly gear the motor to another of the ordinary type for alternating currents namely, an alternating current dynamo used as a motor. The charging of storage batteries would not be difficult with such a machine, even from an alternating current line, though the losses might be considerable.

In the discussion which followed—

Mr. MAILLOUX said: I might add, in corroboration of the statement made by Prof. Thomson, that I am perfectly aware myself that the ironclad dynamo, as we have heard it called very recently, is another of those things that have been done before. I remember distinctly reading one of Prof. Thomson's patents where the direct magnetising effect of the coil on the armature itself is adverted to, and I do not think there can be any dispute as to the fact that it had been brought out before; and I would also state that I myself made experiments with dynamos in which the same thing was made out as early as 1879, and I have small models now which may be of interest at some later time. There is one very interesting feature of it that is mentioned by Prof. Thomson. It think it is the phenomenon which he illustrated by means of his first figure, noting the repulsion and the attraction that takes places when the current is reversed in an ordinary electro-magnet. I could not help thinking at the time of some experiments made some years ago by Elphinstone and Vincent, and about which I once took it into my head to write something. The effect was brought out by Elphinstone and Vincent of the magnetic circuit that we now so well know and use in dynamo-electric machines. I was very much struck by the statement of Faraday in his "Experimental Researches," where he speaks of lines of force expanding during the action of the beginning of the passage of current through a circuit and of their collapse when the current is discontinued or decreased; and I remember

Digitized by Google

making a note in this article (which you will find somewhere in the London *Electrician*, several years back) of experiments or observations made by me to show that that phenomenon was observable in an ordinary electromagnet. I have been able, by means of a delicately-suspended needle, or by a very thin piece of iron wire fastened to the pole—so that it might place itself in the lines of force and follow the oscillations of the lines of force—to trace a positive motion in the lines of force which would exactly correspond to that just referred to by Prof. Thomson.

In answer to Mr. Prescott, Prof. THOMSON said:—In regard to the measuring instruments, I have used the principle in several ways. The matter has not been carried sufficiently far as yet to determine all the points on the subject, but I have used gravity and a spring in both cases. However, I find there does not seem to be any regular law, perhaps any more than there is with an electro-magnet, for the decrease of the effect by distance, except when the distances become very large. The very fact of a change of position changes the relations of the currents themselves and of the relations between the two currents, so that we can hardly regard the problem as any different from the problem of an electro magnet attracting its armature. When the armature is placed at a certain distance, there is a certain distribution of magnetism; when it is taken to another distance the distribution is so changed that we could not consider that the centre of gravity, so to speak, of the magnetism is the same in the two cases, and the re-distribution will depend on the length, the diameter of the core and the sizes of the armatures, so that the problem becomes a very complex one. But I have made a very curious application of the principle in this way: I have taken an ordinary fruit jar and put in it a disc of a certain thickness and attached to it a bulb of glass and floated it in alcohol or water until the gravitational effect was so overcome by the flotation that it was almost indifferent, but it would just settle down to the bottom of the jar. I then put an alternating current coil below it and passed a current of gradually increasing amount. Gradually the disc would begin to lift itself, and at a certain current would float to a certain height, standing in the liquid supported by the repulsion. There we have a very excellent illustration of the means of getting at probably the relational effect of repulsive effort under different conditions.

Mr. CARL HERING: I would like to ask Prof. Thomson how the magnetic attraction compares with its induction. If the closed copper disc were to be made of iron, there would be attraction. Now, how does that attraction compare with the repulsion in case it is not magnetic? I ask that in order that we may get some idea of the strength of this repelling force.

Prof. THOMSON: I have not made any determinations with that object in view—that is, to determine the relation as to, as I understand it, the attraction of the magnet coil for its core. I think we can say, however, that it compares very well, only that the copper band, of course, naturally occupies a greater space, and uses energy of current flowing in it. If we have a current flowing in a coil attracting an iron core, and the iron core is thoroughly divided so as to avoid currents in the iron itself, we would get electro-magnetic attraction pure and simple without necessary loss of energy; but in the case of the copper band there is undoubtedly, where large work is being doing, a loss of energy due to the flow of heavy currents in the conductor; but in the case of a disc which is deflected, the disc saves itself that loss by throwing itself more or less at right angles. It is only when you are resisting the motion by a counterweight that the loss amounts to a great deal. Allow the thing to move, and it relieves itself of the stress by leaving the point of greatest stress.

Mr. J. A. POWERS: I had a very interesting experience in the line of Prof. Thomson's address about the lag of heavy currents which I wish to bring to your notice. At Troy we are making an alternating current dynamo, producing direct currents from it. In other words, a simple multipolar dynamo, with this exception, that the armatures are in two layers, the neutral point on one armature corresponding with the maximum point on the other. Those two armatures are connected to a single commutator, there being two bars connected with one armature and the next two bars with the other; the positive of one and the positive of the other; the negative of one and the negative of the other; in that relation, a brush being put on of a certain width, we found some curious results. With plating machines of low tension we found we could increase the width of contact to such an extent that we seemed to collect the entire current from both sides of the armature; in other words, the current seemed to be prolonged from each side of the armature, so that we were practically collecting the current from both sides. The moment we got to high tension currents we failed. Without apparent lag of the current, or whatever that was, the minute we increased the tension of currents up to two or three or four hundred volts we failed entirely. But the point I wished to bring to your attention was that we could make that contact of considerable width and apparently get a larger power from the same amount of material in the machine in low tension work than we could when we got too high tension, and apparently there existed there this feature of lag of heavy currents which Prof. Thomson first brought up.

Prof. THOMSON: I do not think you can say that heavy currents lag any more than light currents. A heavy current is nothing more or less than the flowing around of so many light currents. In the closed circuit of a coil it is the same current going round many times, as compared, you may say, with parallel currents which represent the current that goes in the fine coil repeated side by side so many times; and the lag ought to be the same in both cases. I find, for example, that it does not matter in these experiments whether I use a copper ring or a closed coil of a finely-wound coil; I might use No. 36 wire, provided I could get as much copper into the same space with No. 36 wire that I could get with a heavy mass of copper. That, of course, I cannot do, but if I could I have not the slightest doubt that the high electromotive force closed on this would have the same lag as heavy currents closed on this. In one case it has greater length; in the other it has greater volume, which lags the current. Mr. Powers is probably working with high potentials in one case and quite low potentials in the other. Now a high potential machine is a ticklish thing to handle anyhow. You must put your brushes on and carry the coil away not a moment too late or you will have a flash and short-circuit of the commutator from one point to the other. I am speaking of the type of machine you refer to. The low potential current, however, permits you to have a considerable variation in the point of connection without provoking bad sparking and flashing; you no doubt need to put the extra overlap of brushes brought on the coils into action at the moment they are developing very low electromotive force, and take them out when they are developing nearly no electromotive force. That you could not do in a machine of that type with high potentials, because if you keep the coils in beyond their time of possessing electromotive force which could just sustain the circuit, you would have a flash; there would be an alternation at the slot in the commutator, which would cause a reverse current.

Mr. POWERS: The action I was speaking of was not flashing at the commutator, but the curious "growling" of the machine against itself; for instance, the relation between ten volts and one hundred volts on the same machine, if you choose to couple them up directly, and the same brushes would give you that slowing down and growling effect, while in the other case the brushes worked smoothly and gave good results.

THE EQUITABLE TELEPHONE COMPANY'S INSTRUMENTS.

The discovery some time since—for discovery it may be called—of the fact that good and practicable telephone receivers can be constructed upon

the lines of the so-called "English Mechanic" telephone (a type which, as is well known, is disclaimed from the Bell patents), is at length beginning to bear fruit, and we have now at least three public companies besides private individuals, who are making instruments of this class, and offering them to the public for sale outright. It will be recollected that this type of receiver consists of a membraneous diaphragm, carrying a small iron disc or amature at the centre.

The possession, however, of a receiver does not finally extricate from difficulty those who are—more or less justifiably—trying to "get round" the United Telephone Company. It is necessary also to make sure that the transmitter does not infringe the claim in the Edison patent—the solitary claim which now remains out of the original thirty. The instrument must contain no diaphragm, and the latter term must be construed according to the "legal" definition, which is well known to be of somewhat extended application. The solution of this difficulty which has been adopted by

Digitized by Google

the Equitable Telephone Company seems, however, to the lay intellect to be perfectly unassailable, while at the same time the complete demonstration of the fact that a Hughes microphone will act by direct impact of sound waves is not without scientific importance. The microphone transmitter employed by this new company (and the particular form of which has been designed by Mr. Campbell Swinton) consists of a row of carbon pencils strung upon a platinum wire, whose lower ends rest lightly upon an insulated horizontal rod of carbon. The whole of these parts are supported by a heavy rectangular frame of lead, and this again is suspended from the back board by means of two short pieces of india rubber, so that no vibratory impulse can possibly be communicated from the board—which would otherwise constitute a legal diaphragm—without passing through the india rubber cords and the heavy lead frame.

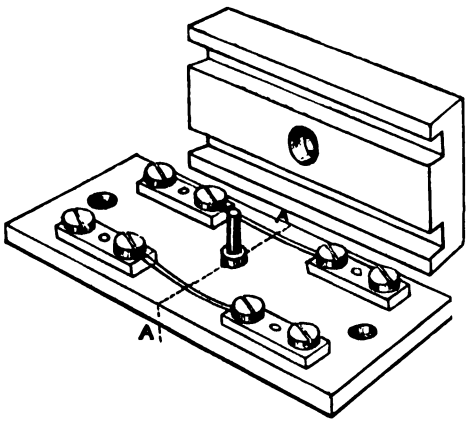
The fact that the action of the instrument does depend upon the direct impulse of the sound waves was recently demonstrated to our own satisfaction by Mr. Campbell Swinton, by taking the transmitter off the frame, and hanging it from the ceiling by means of a long piece of twine. Under this severe test we found the articulation to be just as loud as well as distinct as when the carbons were in their place upon the board.

The pressure of the carbon can be regulated with great nicety by slightly tilting the frame. The company prefers to use a direct battery current to line, dispensing altogether with induction coils, and we are informed that on long lines it has been found that the number of cells required for the transmitter in no case exceeds the number used for the call bells.

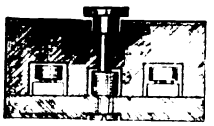
We are indebted to the company for the above engraving.

RASHLEIGH PHIPPS' SLATE-CASED CUT-OUT.

The adjoining figures illustrate the double pole fusible cut-outs made in slate or marble by Mr. Rashleigh Phipps, and to which we referred in a recent note. We may mention that cut-outs of a similar character are also supplied by the United Electric Light Company, and are made with enamelled surface having a very handsome appearance. There can be no two opinions as to the superiority of this make over the old-fashioned wood-cased type. If it were not for the fact that safety-fuses so extremely seldom come into action, there is no doubt that the wooden blocks would long ago have received emphatic condemnation.



Phipps' Slate-Cased Cut-Out.—Perspective View.



Section at A A.

THE TELEGRAPH SERVICE.

DISCUSSION IN THE HOUSE OF COMMONS.

In the House of Commons, on Monday last, on the vote of £1,500,248 for the Telegraph Service,

Dr. CAMERON urged the desirability of revising the bargain made in respect of telegraphs many years ago, and of inquiry as to the amount of waste thereby incurred, particularly with reference to the charges made by railway companies and others for the maintenance of telegraph wires.

Mr. MOLLOY inquired what progress had been made in putting telegraph wires underground, with a view to avoiding the inconvenience caused by breakdowns of overhead wires, especially when great storms occurred.

Mr. H. HEATON suggested that the twenty years' monopoly of the Submarine Cable Company, which expires next year, should not be renewed, but that the cables to the Continent should be owned by the Government.

Mr. RAIKES considered that it was practically not within the bounds of equity for the House of Commons to seek to review an arrangement legally made and entered into with the railway companies as to the maintenance of postal wires. The Government could not, without a breach of equity, attempt to interfere with the arrangement with railway companies for the maintenance of telegraph wires. He was not prepared with the actual figures of the extent of our present system of underground telegraphic communication. The Government was, however, developing that system, especially in London and in large towns. The network of wires seen in London were for the most part not telegraph wires under the control of the Government, but were the property and under the control of telephone companies. The country would hardly sanction a general extension of the underground system, the lowest estimate for which was put at £1,500,000. There were undoubtedly certain dangers from the overhead system, but there was the advantage of greater facility for repair. The question was being carefully considered, and the Department were of opinion that in the metropolis and in large towns underground wires might with advantage be substituted for overhead wires. He called attention to the wonderful celerity with which the damage to the overhead wires last winter was repaired, and expressed the acknowledgment of the Department to the Royal Engineers for so ably seconding the efforts of the Department. Negotiations had already begun as to the policy that should be adopted when the concession to the Submarine Cable Company came to a natural end. He hoped that the Committee would not press for any more positive statement of policy. There was a very full recognition of the paramount importance of the Government having control over the means of telegraphic communication with the Continent.

Dr. CAMERON complained that directors of railway companies made use of the privilege of franking telegrams for other purposes than the regulation of traffic. As the Postmaster-General did not seem to attach sufficient importance to the subject, he moved to reduce the vote by £25,000.

The Committee divided—

For the reduction	60
Against	132
Majority against	—72

Mr. S. LEFEVRE asked whether the £500,000 deficit on the introduction of sixpenny telegrams did not include £350,000 interest on the capital embarked in the purchase of the telegraph system, together with £150,000 or £200,000 for new plant. If this were so, was he not right in saying that an actual increase in revenue had followed the introduction of the sixpenny telegrams?

Sir W. HARCOURT said the net profit of the Postal and Telegraph Services was becoming less and less every year. He should be glad to learn what hope there was of the telegraph service paying its way.

Mr. RAIKES said the position was this, that they had a permanent charge against the revenue of £326,000 interest on capital, plus the actual deficit on the working of £223,000. So that, on the whole, the figures came out for last year as representing a deficit of something like £550,000. A very large portion of the expenditure last year was due to plant, using the word in its largest sense. The number of telegrams sent for some weeks past had exceeded a million per week, compared with 700,000 or 800,000 in the corresponding period of last year, when the sixpenny telegram was introduced. The figures showed that the sixpenny telegram was almost in its infancy, yet the progress which it had made was so rapid that it was almost impossible to forecast the dimensions of its growth. It was impossible to say whether the introduction of sixpenny telegrams had really paid its way or not. Last year they produced a considerable increase of revenue, but there had also been a considerable and a larger increase of expenditure. It was hoped that while in the course of the coming year the revenue would continue to increase, the expenditure would be largely diminished. That being so, he looked with some hope to the future of the sixpenny telegram. It must, however, be seen that the demand for fresh sites, accommodation, and plant must disturb any calculations which might be made.

Mr. S. LEFEVRE said the statement of the Postmaster-General was rather reassuring with regard to the future, showing that the actual number of telegrams had increased to a much greater extent than had been expected, but the average receipt was less, and the two apparently about balanced each other. He suggested that the payments of large amounts of expenditure should be spread over a period of years, so as not to disturb the averages.

The vote was then agreed to.

LEGAL INTELLIGENCE.

Gouraud v. The Consolidated Telephone Construction and Maintenance Company (Limited).

This was an action heard before Baron Pollock and a special jury in the Court of Queen's Bench on Tuesday, in which the plaintiff sued to recover certain fees which he alleged to be due to him as a director of the defendant company, in respect of the period from March 31st, 1883, to August 18th, 1884, when he resigned his seat at the Board. Mr. Fletcher Moulton, Q.C., with whom was Mr. Walter, appeared on behalf of the plaintiff, the defendant being represented by Mr. Finlay, Q.C., M.P., and Mr. Reginald Brown.

In opening the case for the plaintiff, Mr. Walter said in effect that Colonel Gouraud was one of the original directors of the company, appointed under its Articles of Association at the date of its incorporation in 1881, and for a certain time he acted in that capacity, but at a subsequent period of its history found it necessary to resign his position, and for a certain space of time after that the defendant company endeavoured to conduct its business without that gentleman's assistance. Towards the close of 1882, however, the majority

Digitized by Google

of the Board came to the conclusion that the co-operation of Colonel Gouraud was essential to the success of the company's operations which it had then in hand, and they determined to invite him to rejoin the directorate. The result of that decision was that they passed a resolution, on the 18th January, 1883, asking him to become again a director, which he did. Unfortunately, about that time the affairs of the company were not in a very prosperous state, and, in consequence of that, on the 20th of April, the directors as a body came to the resolution to relinquish their fees for the financial year from the 31st of March previously. It was from a misconstruction of this resolution on the part of the defendants that the present action arose. After that resolution had been carried in the month of May a general meeting was held, at which the chairman announced to the shareholders that until such time as the company became prosperous the directors had agreed to forego their fees, but reserved their right to recoup themselves when the company attained more flourishing circumstances. In January, 1884, the chairman of the company, Sir Julius Vogel, was abroad, and during his absence it was necessary that someone should undertake the duties of his position. Accordingly, Colonel Gouraud was invited to assume that responsibility which he did on the 5th of February, but he pointed out that owing to the great labour that it involved, the resolution pledging the directors to forego their fees should be relaxed in his favour, and it was agreed that Colonel Gouraud should be paid at the rate of £1,000 a year, as deputy chairman, during Sir Julius Vogel's absence, in addition to his fees as a director, that portion of his fees up to the 31st March, 1883, only standing, in common with the fees of the rest of the directors, in abeyance. Sometime in May, 1884, a committee of investigation was appointed to inquire into the affairs of the company, and as the result of the report of that committee Colonel Gouraud issued a circular on the 23rd of July to the shareholders, setting forth the circumstances under which he joined the Board. Subsequently, at the general meeting in the same month an attack was made upon him and several other directors, in consequence of which, on the 18th of August, he retired from the Board, and lodged a claim with the secretary for the remuneration due to him from 31st March, 1883, up to the date of his resignation. He (Mr. Walter) would submit that Colonel Gouraud never relinquished his fees for that year, the defendants' case being that he had.

Colonel Gouraud was then called, and gave evidence to the effect that with the exception of pledging himself to the resolution relinquishing his fees down to the 31st March, 1883, he had never undertaken to forego any other claim he had on the company.

Cross-examined by Mr. FINLAY, witness deposed that the part of the circular he had addressed to the shareholders in July in reply to the allegation of the report of the committee of investigation, and which stated, "The report omits to mention that no part of the £1,000 remuneration so provided was drawn by me. I have voluntarily resigned my right to it," referred only to the few weeks he was a director, from the 5th of February (when he became deputy chairman) to the 31st March, 1883. Some correspondence between the secretary and Colonel Gouraud, as well as a circular issued simultaneously to the shareholders by Messrs. Spensley and Carnegie, then directors, who said "we think it right to say that Colonel Gouraud rejoined the Board of your company in January, 1883, at the earnest and repeated solicitations of the Board, and that of the remuneration of £1,000 a year referred to in the report nothing whatever has been paid to Colonel Gouraud, and for the year in question was voluntarily relinquished by that gentleman," were then submitted, witness alleging that the latter statement had also reference to the few weeks' tenure of his office prior to the 31st March, 1883.

The Hon. Mr. Spensely was next examined in support of the plaintiff's case, and in the course of cross-examination admitted that he could not positively say that the statement quoted from the circular, of which he was the joint author with Mr. Carnegie, referred to the whole year ending 31st March, 1884, or to the portion of the previous twelve months during which Colonel Gouraud was a director.

Mr. FINLAY, on behalf of the company, contended that the statements of the circulars referred to could bear no other interpretation than that they had reference to the whole of the financial year, from the 31st March, 1883, to the 31st March, 1884, in support of which contention he emphasised the fact that neither of the circulars saw the light until July, 1884, and could only refer to that period. He further contended that at the general meeting in July Mr. Fitzgerald, who was then chairman of the company, congratulated the shareholders, in the hearing of Colonel Gouraud, that the latter, in conjunction with the rest of the Board, had waived his right to his remuneration for the period in question. It was true that his learned friend maintained that Colonel Gouraud on that occasion muttered the words "mine refers to the previous period," as appeared by the shorthand notes of the proceedings, but if Colonel Gouraud made use of that expression, it was audible only to the reporter and to the chairman, and could not be regarded as a serious argument in the plaintiff's favour, more especially as on the conclusion of the chairman's speech Colonel Gouraud himself addressed the meeting for half an hour, and made no further allusion to the circumstance, and did not openly deny in the hearing of the shareholders—which he ought to have done—that he had agreed to forego his fees for the whole of the financial year ending 31st March, 1884.

Mr. Fitzgerald, Mr. Baker, Sir William Armstrong (directors), and Mr. Curtoys (secretary to the company) were then called, and gave evidence in support of Mr. Finlay's contention, Mr. Fitzgerald alone admitting that he heard Colonel Gouraud in a subdued voice use the words "mine refers to the previous period" at the general meeting in July.

Mr. Taunton, the shorthand writer who supplied the report of the proceedings, swore to the accuracy of his notes, which concluded the evidence on both sides.

Mr. FINLAY and Mr. MOULTON having each addressed the jury,

His LORDSHIP summed up, reviewing the whole of the documentary and other evidence, and

The Jury, after a short deliberation, found for the plaintiff, allowing him £1,091. 4s. 7d., the amount claimed, minus the sum paid into court by the defendants.

Von Chauvin v. Anderson and Others.

This was an action of libel heard before Mr. Baron Pollock and a special jury, on Wednesday last, in respect of a paragraph which was published in October, 1886, in *The Electrician*, a newspaper belonging to the defendants, and which, it was alleged, imputed fraud to the plaintiff. The defence to the action was a denial that the paragraph in question bore the meaning complained of, and the defendants further pleaded that they had published an apology, and they paid 40s. into court.

Mr. R. T. Reid, Q.C., and Mr. Arbuthnot appeared for the plaintiff; Mr. Finlay, Q.C., and Mr. Pollard were for the defendants.

The plaintiff was the principal official in the United Kingdom of the Western Union Telegraph Company, who, besides possessing a network of telegraph wires on the American Continent, are also the lessees of two Atlantic cables connecting Nova Scotia with England, and the libel in question, which was headed "Telegraph Frauds," was as follows:—"Serious accusations are brought against certain of the local officials of the Western Union Cable lines as to systematic tampering with or delaying Stock Exchange messages; whereby it is believed large sums have been fraudulently obtained." The plaintiff having complained of this paragraph as being utterly false, the defendants inserted an apology in their paper, the terms of which, however, were not considered satisfactory, and it was not until after the writ was issued that they published a second apology in which they acknowledged the statement to be entirely erroneous, and repeated an expression of regret which they had previously made that it should ever have caused annoyance to the plaintiff.

Mr. REID, in opening the case, having referred to the general facts, said the plaintiff would be content if this apology, which appeared so late and had not been published as the plaintiff required in *The Times* as well as *The Electrician*, should now be made in open court.

Mr. FINLAY said the apology was ample; and he did not see that he could add anything to it.

The plaintiff was then called, but his examination had scarcely commenced when a consultation having taken place between the learned counsel at the instance of the learned judge,

Mr. FINLAY said it was agreed that a juror should be withdrawn. He desired to state at the same time that it was never intended to convey any imputation whatever on the plaintiff or any other English official of the company, nor did he believe that the paragraph was read by the public as intended to refer to the plaintiff. Several of the defendants were themselves interested in the plaintiff company and were obviously, therefore, the last people to wish to discredit it, and he might add that the paragraph would never have appeared at all but for the accident of the editor being absent at the time.

Mr. Baron POLLOCK said the course that had been taken was a good illustration that unless a real charge was intended to be made the apology should be handsome and complete. Half-hearted apologies were very poor things, and sometimes tended to aggravate the original attack. He was sure a better end had been made of this case not only for the plaintiff, but for the defendants, than by any verdict which the jury might have given.

[The above is *The Times* report of this case, with one alteration, or rather correction, "Union" for "Atlantic," in the 16th line.—ED. *E.*]

CRICKET.

SS. "ELECTRA" v. MALTA ATHLETIC CLUB.

A match was played at Valetta Parade Ground, Malta, on May 28th last, between these elevens. We append the score:—

MARRIED V. SINGLE.

A match was played at Waterville, Co. Kerry, on Whit Monday, between the Married and Single members of the three cable companies (Anglo-American, Valentia; Direct U. S., Ballinskelligs; and Commercial, Waterville). The weather, though cloudy, was fine and favourable. There being some fairly good cricketers on both sides, this match had been anxiously awaited by all parties and was looked forward to with much interest.

The married team was captained by Mr. J. Graves (Valentia), and the single team by Mr. L. Carmichael (Waterville). Mr. Graves having won the toss, and several of his men having just completed a twelve mile drive, put in his opponents first. The ground was in good order.

Digitized by Google

The single men, by careful play, put together 61 runs in their first innings, but owing to some inexplicable bad luck all the married wickets fell for only 15 runs.

In the second innings the single men added 31 to their score, and the married team had to face an apparent forlorn hope of pulling up a leeway of 77 runs Nothing daunted, and placed on their mettle with this state of affairs, the effort was commenced, but with the fall of the two first wickets not a single run had been scored in their favour. Messrs. Armstrong and Smith then succeeded in making a stand, which made the game assume a more hopeful appearance. Well supported in their efforts by those who followed them, a tie was at length reached amidst great excitement and the captain, by a fine hit for two, secured the palm for the married team with three wickets to spare.

EASTERN TELEGRAPH COMPANY v. ST. MILDRED'S.

To the Editor of the "Electrician."

SIR,—In your issue of the 3rd inst., under the heading "Cricket," The Eastern Telegraph Company v. The St. Mildred's C.C., I notice it is stated that the latter team was "mainly composed of *employés* of the Anglo-American Telegraph Company." Now there was only one man playing who is in any way connected with this company, and to the surprise of many, himself included, he made the top score for St. Mildred's. As your paper is forwarded to all the stations of our company, I feel sure you will correct the inaccuracy by inserting this in your next issue.—Yours, &c.,

R. J. EDWARDS, Captain A. A. T. C. C.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended 31st March last, and payable on the 24th inst. The books of the company will be closed from the 16th to the 23rd inst, both days inclusive.—The traffic receipts of the company for the week ended 3rd inst. amounted to £4,473.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of May was 4,040, estimated to produce £3,050, against 3,744 messages, producing £3,103, in the corresponding month of last year. The traffic receipts for the month of February, estimated at £3,000, realised £3,009.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for May amounted to £1,557, against £1,709 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—This company have declared an interim dividend for the quarter ended March 31st of 2s. 6d. per share, free of income-tax, payable on July 15th.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for May amounted to £22,000. From 1st January to 31st May they amounted to £103,520, and in the corresponding months of 1886 and 1885 to £100,960 and £118,000 respectively.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ended May 31st amounted to £4,800.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 31st May are £3,364, as compared with £2,996 in the corresponding period of 1866.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 3rd June were £3,618, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE SCHOOL OF SUBMARINE TELEGRAPHY AND ELECTRICAL ENGINEERING.

ESTABLISHED IN 1868.

12, Princes Street, Hanover Square, London, W.

Manager: Wm. LANT CARPENTER, B.A., B.Sc., F.C.S.
Secretary: LEON DRUGMAN, A.S.T.E.
Senior Instructor: H. D. WILKINSON, M.S.T.E.

THIS Establishment is now the largest and the most fully equipped School of its kind. It possesses, among recent additions, several dynamo machines and electric motors, a 6-horse boiler and steam engine, a gas engine, 42 E.P.S. accumulator cells, lathes, &c., as well as several kinds of arc and incandescence lamps and a photometer room. Both theoretical and practical training can therefore be obtained. Since its opening in 1868 more than 3,000 Pupils have passed through the School. At the end of the course of instruction, an Examination for the CERTIFICATE OF THE SCHOOL is conducted by an Examiner of high standing, unconnected with the School. New courses usually commence early in January, May, and September.

For full prospectus, terms, &c., apply to the Secretary, 12, Princes Street, Hanover Square, W.

Digitized by Google

NOTES.

SHIP LIGHTING.—All the Great Eastern Company's steamers, except the two oldest, are now lighted by incandescent lamps.

BRIGHTON.—The Brighton Corporation have decided to extend the period for receiving tenders for the lighting of the Pavilion until Monday, the 25th instant.

"A CENTURY OF ELECTRICITY."—Messrs. Macmillan and Co. send us a copy of "A Century of Electricity," by T. C. Mendenhall, of Washington, U.S.

PERSONAL.—Mr. John Rance, jun., has been nominated by the City Guilds Institute to the vacancy offered by the Anglo-American Brush Electric Light Corporation for a pupil without premium.

LEAMINGTON.—Much disappointment is felt at Leamington owing to the inability of the contractors to complete the electric lighting of the Parade by the date of the Jubilee celebrations.

BRUNSWICK.—The municipal authorities of the City of Brunswick have decided to ask for tenders for the construction of a central electric lighting station and the supply of current to the inhabitants.

NEW BOOKS.—Messrs. Whittaker and Co. will publish early next week Mr. E. C. Robins' book "On the Design and Construction of Applied Science and Art Buildings, and their Suitable Fittings and Sanitation."

THE BELL TELEPHONE SUIT IN THE UNITED STATES.—The United States Supreme Court, at its meeting on May 27th, did not announce a decision in the telephone suits, as was confidently expected by some of the parties concerned.

THE QUEEN'S JUBILEE CELEBRATION BY ENGLISH ELECTRICIANS IN AMERICA.—The electricians of English nationality or descent now living in New York have arranged to dine together on the evening of the 21st inst., in celebration of the Queen's Jubilee.

ACCUMULATOR WORK.—The North British and Mercantile Insurance Company have determined to increase their battery plant, and Messrs. Drake and Gorham inform us that they have obtained the order for the new battery, which will consist of 53 cells, type 23L, in glass boxes.

MULHOUSE.—The town of Mulhouse has recently concluded a contract with Messrs. Siemens and Halske, of Berlin. The firm will undertake the supply of electric light, the conditions being that when the profits exceed a certain amount a fixed percentage becomes payable to the local authorities.

PROF. S. P. THOMPSON'S "ELEMENTARY TEXT BOOK OF ELECTRICITY AND MAGNETISM."—Messrs. Macmillan have just completed the issue of the twenty-sixth thousand of this excellent text-book. In the last edition the chapter on Electro-Magnetics has been rewritten and considerably extended.

FORTHCOMING SALE OF ELECTRICAL PLANT.—We would call the attention of our readers to a notice which will be found in our advertising columns of an important sale of electrical plant by Messrs. Wheatley Kirk, Price and Goulty. The sale takes place at Fulham on Thursday and Friday next week.

TELEPHONE EXTENSIONS IN SPAIN.—The Madrid *Gazette* of June 13 contains instructions for the establishment of a telephone service in the towns of Alicante and Ovieds. Tenders for the establishment and working of a line are invited up to 18th July in the case of Alicante, and for the following day in the case of the northern town.

THE JUBILEE ILLUMINATIONS.—In another column will be found some account of the electric lighting arrangements for the illuminations of the 21st inst. We have taken a good deal of trouble to render the list fairly complete up to the time of going to press on Thursday evening, but we need hardly say it by no means covers the whole ground.

THE GERMAN-EDISON COMPANY.—The report of this company (to which we alluded in our last issue) states that up to the end of 1886 the company had erected 260 installations, including 70,000 incandescent and 1,000 arc lamps. The sales of incandescent lamps for the year 1886 had amounted to 90,000, against 60,000 for the preceding twelve months.

BARCELONA.—The municipality of Barcelona has concluded a contract with the Sociedad Espanola de Electricidad for lighting some of the streets of the town with arc lamps during a period of five years. There will be 33 lamps in all, of which those which burn until morning are charged for at the rate of five shillings (nearly) per night, and those which are extinguished at 1 a.m. at the rate of three shillings per night.

THE DURHAM COLLEGE OF SCIENCE.—On June 15th Sir W. Armstrong laid the foundation stone of a new building for the Durham College of Science at Newcastle-on-Tyne, to cost from £20,000 to £25,000. Sir William, speaking afterwards at a luncheon in connection with the event, said what they now wanted was a bread-winning science, and it was owing to its absence that they were experiencing the results of foreign competition in manufacturing industry.

THE TELEGRAPH IN CHINA.—HOSTILITY OF THE PEOPLE.—The recent determination of the Chinese Government to extend their lines of telegraph communication in the interior of the country is meeting with serious opposition in some of the provinces. The workmen engaged have been repeatedly attacked, and in some cases the work has been altogether suspended. The villagers plead that the wires have a bad effect upon evil spirits, and tend to keep them awake at night.

LIEGE.—The Hall of the Conservatoire of Liege will, it is said, be the first theatre or concert room in Europe to be lit entirely with arc lamps. The lamp selected is the Pieper, of which very little has yet been seen in this country. The dynamo machines have also been specially designed for this service by M. Pieper, and are driven by a gas engine supplied by MM. Fétu and Deliege. Two of these machines give each 65 volts and 300 amperes, and there are in all 29 arcs.

BRUSSELS.—In the Rue Neuve at Brussels some shops have been recently supplied with an electric light installation by Messrs. Gerard and Co. A Kortling gas engine of ten horse-power drives a Gerard dynamo of 110 volts and 50 amperes which feed 6 arcs (system Piette) of 8 amperes and seventy-one 20 candle-power incandescents. Although the engine does not obtain power at every stroke the installation runs with great steadiness owing to the dynamos being provided with a very heavy fly-wheel.

THEATRE LIGHTING IN BRUSSELS.—Immediately after the disaster at the Opera Comique a petition was presented to the Conseil Communal of Brussels praying that the Theatre de la Monnaie might be lit by electricity. We are informed, however, that it had already been decided to do this, although it will entail extensive alterations, the side rooms of the theatre being at present warmed as well as lighted by gas. The engines and dynamos will probably be placed in the cellars of the new General Post Office, which is close by.

A SHOCK FROM AN ALTERNATING CURRENT MACHINE—Our contemporary, *Electricité*, contains an account of an acci-

Digitized by Google

dent—happily without serious results—which occurred during some laboratory experiments with alternating currents. The machine was giving 300 volts at the terminals when they were accidentally touched by the experimenter with two fingers of the same hand. The shock was severe and was accompanied by an intense sensation of heat in the fingers, leaving a scar resembling a burn on the surface of the skin.

WILD GEESE KILLED BY LIGHTNING.—During a severe storm in California, on April 29th, a flash of lightning was observed to pass apparently right through a flock of geese which were flying high overhead. Six birds fell to the ground and were picked up dead, having evidently been killed by the lightning, although no mark was found upon them. This is believed to be the first instance on record of geese being struck by lightning while flying, ancient tradition asserting that this bird is safe from the destroying bolt of Jove.

MANILA.—The Philippine correspondent of a Madrid paper states that the Electric Light and Power Company have made a proposal to the municipal authorities to supply Manila with the electric light. The proposal provides for the erection of 1,000 incandescent and 100 arc lamps, extending over a length of 27 kilometres, the concession to last 40 years, and the municipality to make an annual grant of $40,000, besides allowing 6 per cent upon $145,000, the estimated total cost. The matter is under the consideration of a committee.

ELECTRIC TRAMWAYS IN NEW SOUTH WALES.—According to the *Colonies and India*, a rumour is current in New South Wales that the Government proposed to introduce into the colony a system of electric tramways, "and," says the journal above quoted, "it was asserted that a wealthy capitalist had taken time by the forelock and purchased the colonial right from the patentees for £10,000." We do not know who *the* patentees may be, but they may certainly consider themselves lucky individuals to get £10,000 for an electrical patent nowadays.

THE RECENT ILLUMINATION AT THE LAW COURTS.—We are requested to state that the coloured lamps used at the recent meeting of the Incorporated Law Society were Shippey Bros.' patent 8 and 10-volt low-resistance lamps specially made to run in series of 10 and 12 lamps on the Edison and Swan 100-volt circuit. This installation was successfully carried out by Messrs. Bailey and Grundy, and is good evidence of the value of a practical low-resistance coloured lamp for decorative and illuminating purposes in places where electric light plant is already installed.

MORE INCANDESCENT LAMP LITIGATION IN AMERICA.—We learn that Dr. Woodward, the inventor of Woodward's incandescent lamp, is at present travelling through the States obtaining special information with a view to institute proceedings against a number of firms for infringements of the Woodward patent rights, which are said to be in full force in Canada, Germany, and the United States of America, the former being granted in the year 1872, and the latter in 1874. This step has been taken in consequence of the recent decision of the Supreme Court of the United States in upholding the Nelson-Green patents.

FOREIGN TELEGRAMS.—In the House of Commons, Mr. Raikes, in answer to Mr. Montague, stated that he was in communication with the Telegraphic Administrations of some of the neighbouring Foreign States with regard to the arrangements which it would be necessary to make for the transmission of telegrams between this country and those States, when the concessions now held by the Submarine Telegraph Company from France and Belgium expired in 1889. He did not think that he could promise to submit these arrangements to the Chambers of Commerce, but he should be ready to consider any suggestion that they might desire to make.

THE LONDON TELEGRAPH CLERKS.—A meeting of the staff of the Central Telegraph Office was held on Wednesday night in the Lecture Hall of the Young Men's Christian Association in Aldersgate-street. Much dissatisfaction was expressed at the unfavourable replies given by the Postmaster-General to recent petitions. It was resolved that another petition should be presented to him drawing strong comparisons between the pay and privileges of the Telegraph Staff and those of other branches of the Civil Service, and asking for increased pay, extension of annual leave, and other benefits. A resolution was also passed asking that some equivalent should be granted to the clerks for their additional work on Jubilee Day, which in other Civil Service departments will be a general holiday.

ELECTRIC LIGHTING IN THE NAVY.—On Wednesday night, the 8th inst., some interesting experiments were made on board H.M.S. "Hero" at Chatham, the object of which was to afford the dockyard and naval officers an opportunity of comparing the respective beams of light thrown from two projectors, one being fitted with a Mangin reflector and the other with Ronald D. Scott's new mirror. At the conclusion of the trial the verdict was unanimous in favour of Scott's mirror, the beam from it being far more intense and of a purer white. The benefit of the latter feature was readily seen, the objects illuminated appearing in their natural colours. Mr. Scott was warmly congratulated on his success. This exhibition had been specially sanctioned by the Lords of the Admiralty owing to the favourable report received from the Portsmouth officers who have had Mr. Scott's mirror under trial.

STUDENTS' MEETING OF THE SOCIETY OF TELEGRAPH-ENGINEERS.—The third and last meeting (for the present session) of the students of the Society of Telegraph-Engineers and Electricians was held on Thursday, the 2nd inst., W. Lant Carpenter, Esq., B.A., B.Sc., chairman. After a few remarks with reference to the action of the Council of the Society of Telegraph-Engineers and Electricians in promoting students' meetings, the chairman called upon Mr. Wordingham to open the discussion upon Mr. Kapp's paper, "The Pre-Determination of the Characteristics of Dynamos." Mr. Wordingham briefly described Mr. Kapp's method, and then gave an account of that used by Drs. Hopkinson, showing some curves representing calculated and observed characteristics, after which Messrs. Rance, Hayne, Cooper, Healing, Dykes, and Lamb continued the discussion. The chairman then closed the proceedings, after a vote of thanks had been passed.

SOCIETY OF ARTS CONVERSAZIONE.—The annual *conversazione* of the Society of Arts was held at South Kensington Museum on Wednesday evening. Promenade concerts were given throughout the evening simultaneously in the North Court by the string band of the Royal Artillery, and in the courtyard by the band of the Royal Horse Guards (Blue). Two vocal and instrumental concerts were also given by the scholars of the Royal College of Music, and the various picture and art galleries, as well as the main corridors, were gaily illuminated. Between seven and eight thousand guests were entertained during the evening, the arrivals being received by Captain Douglas Galton, C.B., the chairman of the council, and representatives of every branch of art, literature, and science, as well as many social and political notorieties, were among the assembled company. The *conversazione* was continued until a late hour, it being long after midnight before the guests dispersed.

TEMPORARY ELECTRIC LIGHTING AT CHELMSFORD.—During the Agricultural Show at Chelmsford, on the 7th and 8th inst., Messrs. R. E. Crompton and Co. gratuitously lighted the main street of the village. The lighting consisted of a circuit of about two miles of wire, as the works are some distance off. Twelve Crompton lamps were used, the power being supplied by a small Marshall engine. The insulated wires were carried down the street on ropes fastened from chimney to chimney. The lamps were also supported by ropes, and made a very effective combination with the numerous brightly coloured flags with which Chelmsford was decorated. The whole work was done in 37 working hours, the fire escape being used for fixing the lamps. Another temporary installation was put up in the show ground itself, the dog show being artistically illuminated by six small Crompton lamps giving about 500 candle-power each. By the courtesy of Messrs. Marshall this installation was driven off one of their engines.

ELECTRICAL SIGNALLING FOR MINE SHAFTS.—Considering the fact that the number of fatal accidents occurring during the ascent or descent of mine shafts has for the last six years averaged 174 per annum, it is somewhat astonishing that an efficient means of communication between the occupants of the cage and the man in charge of the winding engine was not long ago adopted. A very simple method of effecting this has recently been devised by Mr. William Armstrong, jun., of Wingate, and is now in use at the Wingate Grange Colliery, county Durham. It consists merely in placing an insulated conductor within the winding rope and making connection with a battery and bell in the engine room and with a key fixed in the cage. The circuit is completed through the sheathing of the rope. This device will doubtless commend itself to all managers of collieries and other mines, especially as the expense is, or should be, comparatively trifling. If the signalling on the bell does not meet all requirements it may, of course, be supplemented by a telephone.

THE HASTINGS ELECTRIC LIGHT COMPANY.—The fifth annual report of the Hastings Electric Light Company, just issued, includes a statement of accounts for the year ended March last. The company has now, on three circuits, 30 arc and 704 incandescent lamps, as against 27 arc, and 576 incandescent lamps at a corresponding period last year, showing a steady increase in the company's business. The sum of £3,186, the amount given up by the liquidator of the Hammond Electric Light and Power Supply Company has been placed to the reserve account, to meet depreciation on plant and machinery. The revenue account shows a gross profit of £248 on the total receipts of £1,835. Against this, however, must be charged the amount paid for interest on bank over-draft and loan, viz., £247, thus leaving a net profit of £1. 5s. 3d. The directors consider that a determined effort should now be made to pay off the over-draft, and also raise a sufficient further sum of money to enable them to extend their operations. They suggest the raising of £5,000 by debenture bonds.

TRAMWAYS—ANIMAL VERSUS ELECTRIC POWER.—A writer in the *Age of Steel* sums up the advantages of the employment of electric traction for street tramways as follows:—"1. Not so much real estate is required for the station as for the stable; nor is the location or the character of the building so much a matter of importance and cost with the former as with the latter. 2. The annual loss in efficiency of, say, one-fifth of the live stock employed, whereby twenty animals out of every hundred are sold for a song, is avoided. 3. The cost of attendance is very materially reduced. 4. There is no liability to epizooty, costly in respect of both live stock and traffic. 5. There is no likelihood of the motive power 'eating its head off' during a strike, or while idleness is enforced by any one of a number of causes. 6. The efficiency of the horse in extremely hot or cold weather is at its lowest, though it should be at its highest—which is another and the final point in favour of electricity, if we leave speed out of account." To this may be added the reduction in working cost, which practical experience is daily showing tells heavily in favour of electricity.

SEACOMBE.—A small installation of electric light has lately been carried out by Messrs. J. F. Waddington and Co., Seacombe, near Liverpool, at the works and house of W. Mosley, Esq, Springfield, Cheadle. The installation consists of a Hill patent dynamo driven from an engine in the works and run during the day to charge a set of E P.S. accumulators in the cellar of Mr. Mosley's house, the lamps being lit during the evening from the accumulator. The electroliers and fittings have been supplied by Messrs. Verity and Sons. During the winter months, when the dynamo has finished charging the accumulators it will be used to light two arc lamps of 4,000 candle-power in the works. The dynamo measures 22½in. long over all, 12½in. wide, and 22½in. high. The armature is 6in. diameter and 3½in. long. The magnets are of Nordenfelt's patent mitis metal. It is capable of giving a current of 100 to 110 volts and 20 amperes at a speed of 1,800 revolutions per minute. When wound for an E.M.F. of 50 to 55 volts it will give a current of 55 amperes at the same speed. The installation has been designed and its erection superintended by Mr. Claude W. Hill.

BURNING OF THE NEW ZEALAND GENERAL POST OFFICE—The *Melbourne Argus* of the 2nd of May gives some particulars of the burning of the Post Office at Wellington on the 28th of April. The telegraph room, the telephone exchange, the accountants and Postmaster-General's branch, the Customs Office, and the Post and Mail Offices were in less than two hours completely destroyed. The damage is estimated at between £30,000 and £40,000. There are heavy losses in records, but the telegraph documents were mostly in the safe. About £2,000 worth of telephones were saved. Everything was cleared out of the Post Office, and the *employés* began sorting mails at once in the street. The telegraph office is now located in another building. Luckily a complete set of tables and instruments designed for Napier were in store, and ready to set up at once. The Post Office is temporarily located in a shed on the wharf. The building, which is a new one, was taken over by the Government about three years ago, and cost, with fittings, £27,000. Amongst the most valuable portions of the plant destroyed was the electric light apparatus, which recently arrived from home, and was in course of erection. There was no insurance, the Government taking their own risks.

THE VIENNA TELEPHONE EXCHANGE.—A correspondent in Vienna writes us as follows:—The Vienna Privat Telegraphen Gesellschaft, the owners of the Vienna Telephone Exchanges, have just entirely reorganised their whole system, and united all their subscribers into one single central exchange, a work of great magnitude, considering that Vienna is the only large town that has underground cables, Paris having the advantage of the wonderful system of sewers for their cables. The new switch-board they have now put up for 2,000 subscribers is undoubtedly the best board at present in use in Europe, being a multiplex somewhat like the American, but with numerous alterations and great improvements, designed by the company and their clever constructor, Mr. Otto Schaffler, who also

Digitized by Google

executed the work. The cost of this board has been very great; it is of exquisite workmanship and finish. The company succeeded in making all these alterations and putting up the new board without a single subscriber being cut off or the service interrupted even for one day, a feat very creditable to to the company's manager and engineer. Anyone interested in telephony, and desiring to see the best board, could not do better than get an introduction to the company's general manager and see the Vienna Exchange.

PROJECTED NEW SERVICE BY THE UNITED TELEPHONE COMPANY.—We understand that the directors of the United Telephone Company are taking into consideration the desirability of establishing a new service over their wires of a somewhat similar character to that at present supplied by the Exchange Telegraph Company. Those subscribers who wished to avail themselves of the service would be provided with an automatic type-writing receiver, which would at certain intervals be automatically switched on to the line wire and would deliver Stock Exchange quotations or such other information as may be arranged for. Of course the details have still to be elaborated, the United Telephone Company not having as yet finally decided to undertake the service. Provided, however, that thoroughly efficient instruments are employed, we see no reason to doubt that the service would rapidly become popular. We may add that at the offices of the company we were recently shown the instruments which were then under trial, and although it is too early to speak with confidence, there appeared much probability of their practical success. No battery or clockwork is required outside the transmitting office, and although a large number of receivers may be worked from one transmitter, yet each instrument is readily controlled and adjusted from the central station.

MAGNETISED IRON IN THE VOLTAIC CELL.—At a recent meeting of the Berlin Physical Society Dr. Gross explained his theoretical views on the heat of solution of magnetised iron, leading to the conclusion that the heat of solution of magnetised iron must be greater than that of unmagnetised. One result of these views was that a piece of magnetised and unmagnetised iron in a conducting fluid capable of dissolving the iron must give a current; this he has already demonstrated two years ago. The current in such an element as this flows across the fluid from the magnetised to the unmagnetised pole, and is independent of the nature of the magnetisation. The source of the electric current is in this case, according to the views of the speaker, to be sought for in the loss of specific magnetisation which the molecules of iron undergo as they pass from the solid to the fluid condition. Of the various solutions of salts of iron which were used in these experiments, only neutral salts of ferric oxide were found to yield a result, while the salts of ferrous oxide gave no current. The cause of this is, according to the speaker, that only the ferric salts lead to a solution of the magnets. Dr. Nichols has quite recently carried on some experiments on the heat of solution of magnetised iron, and has obtained the same experimental results, namely, that the heat of solution of magnetised iron is greater than that of unmagnetised, although he starts with theoretical views respecting the magnetic potential of solid iron and iron in solution which are diametrically opposed to those of Dr. Gross.

ELECTRIC LIGHTING BY COMPRESSED AIR-POWER.—The system of distributing power, principally for electric lighting, by compressed air, which was commenced some twelve months ago in Paris by M. Victor Popp, has met with a very fair degree of success, notwithstanding its want of economy. This has arisen in part from the fact that the motors are far less troublesome to work than gas engines, and the whole of the attendance required can readily be provided by unskilled labour. Moreover, in certain cases, for restraurant keepers more especially, the refrigeration produced by the expansion of the air is regarded as a feature of very considerable value. The total efficiency of the compressed air plant is believed, however, not to be much higher than 10 or 12 per cent. At Paris the works are established at Saint-Fargeau, and the conduits are carried to a total distance of 10 kilometres. It is estimated that, after allowing for the loss of power due to the heating of the air during compression, at least 50 per cent. of the available pressure is lost by leakage by the time the extremity of the line is reached. After this we have to allow for the efficiency of the air engine, and of the dynamo. However, as the cost of producing one horse-power at Saint Fargeau does not exceed 6 to 7 centimes per hour, and as M. Popp receives as much as 70 centimes per horse-power hour in the Chausée d'Antrim, a margin of profit would be left, even with a 10 per cent. efficiency. We understand that the offices of the journal *Le Figaro* will shortly be lit with 400 lamps by this system.

ELECTRO-MAGNETIC TERMINOLOGY.—We would call attention to the fact—which will no doubt be welcome to the majority of our readers—that in the present instalment of Mr. Oliver Heaviside's remarkable investigations on "Electro-Magnetic Induction and its Propagation," he repeats and classifies the new terminology which he has been employing in this series of papers. This terminology will no doubt gradually win its way into general acceptance, and has, indeed, already been adopted by several of the leaders of the scientific world. The want of an adequate and settled form of nomenclature to express certain electrical phenomena whose importance has only of late received recognition has been forcibly demonstrated by the fact that scarcely any two writers have made use of the same word to express even the more practically important of these phenomena. For instance, the effect produced in a circuit traversed by an alternating current which tends to reduce the current, and which is a function of the resistance, the inductance (self-induction) and the periodic time of the alternations, has been called by various writers "apparent resistance," "virtual resistance," "choking effect," "induced resistance," "effective resistance," and half a dozen other names, all more or less objectionable. This Mr. Heaviside appropriately terms the "impedance," and he incidentally throws out a hint to Messrs. Sharp and Kent, and others of our practical men, to make use of the term "impeder" (accented on the second syllable). Then, again, the inductive capacity of a conductor is termed the "permittance"—a word which carries its own recommendation upon the face of it. We may also call attention to Mr. Heaviside's disapproval of the use of the term "magnetic resistance."

COST OF ELECTRIC LIGHTING AT DRESDEN.—The experimental electric lighting installation at the old town Municipal Buildings, at Dresden, has now been in operation long enough to give reliable data with regard to its cost and general efficiency. The installation has been carried out and maintained under the supervision of the manager of the gasworks, who has recently drawn up a report and enumerated his principal conclusions to the *Journal für Gasheleachtung*. The requisite power has been obtained from a constant current dynamo made by Messrs. Siemens and Halske, driven by a gas engine and placed in a ground floor room at the back of the buildings. The light was obtained from 93 incandescent lamps, afterwards increased to 94, and consisting partly of 16 candle-power Edison lamps, and partly of 25 candle-power Siemens lamps. During the first three months, from the 1st of October

Digitized by Google

to the 31st of December, 1885, 55 lamps on an average were in use for 77 days; from the 1st of January to the 31st March, 1886, 59 lamps for 74 days; and from the 27th of September to the 31st of December, 1886, 77 lamps for 81 days. The cost of maintenance per lamp was found to be for the first period £3. 6s. 10½d., for the second £2. 3s. 3½d., for the third £1. 15s. 1d., and, allowing for the rental value of the machine room, and 8 per cent. for interest on capital and for depreciation, the amounts were estimated at £5. 6s. 4½d., £4. 6s. 3d., £2. 19s. 9d. respectively. The relatively high cost during the first three months was chiefly due to the various alterations and improvements which were found to be desirable, and also to the almost exclusive use in the first place of Edison lamps, which were found to require a relatively high expenditure of energy entailing a correspondingly high cost. The municipal council of Dresden are thoroughly satisfied with the results already obtained, and they have resolved on a further extension of the installation.

THE FRENCH TELEGRAPH SERVICE.—Some singular allegations have recently been made with reference to the French Telegraph Department, which, if true, would show that the *employés* have far more serious grounds for dissatisfaction than have ever existed in the English service. However, we are unwilling to believe, without further evidence, that the internal administration of any department of the French Republic can be so rotten as here represented. We quote the following from the *Evening Standard*:—"The *employés* of the Posts and Telegraph Department in France have a grievance against the late Minister of that Department, M. Granet, to which they venture to give utterance now that he is no longer their superior. It appears that M. Granet had a large number of personal supporters and *protégés* to oblige—and in this he in no way differed from the majority of French politicians who take office. To oblige them, however, and to provide them with snug berths he utterly disregarded—so it is complained—the most elementary rules of promotion; and whilst old clerks were unable to obtain a modest rise of a hundred francs on the score that there were no funds disposable, thirty-seven, or more, supernumeraries were made permanent clerks, with good salaries, and without passing the necessary examinations. It is related of M. Granet that being anxious to be civil to a Radical journalist, and there being no vacant post for him, he created one of chemist, though the man of the press admitted he knew nothing whatever about chemistry, and could not even study that branch after his appointment, because it would interfere with his newspaper occupation. He could, however, and did, draw his salary—as this did not interfere with what he had to do on the press. Nearly a thousand signatures of postal and telegraph clerks are affixed to the petition that has been presented to the new Minister of their department, begging that an investigation into the matter may be made. If, as is asserted, salaries to the amount of 70,000fr. have been irregularly bestowed by M. Granet on his *protégés*, that gentlemen will await, we should think, with some misgivings the result of the inquiry—should one be held."

BOSTON, U.S.—The following description of a new central lighting station in this town is given in the New York *Electrical World*:—"The Citizens' Electric Light Company, of East Boston, on Monday, May 16, occupied its new station on the site of the one burned March 4. The new building is of brick, only one story in height, but, owing to the conformation of the ground, is nearly 30 feet from floor to roof inside. The floor is of massive timbers, the spaces between which are filled solid with coal ashes, planked with 2 inches of spruce, and crossplanked on top with narrow, hard pine flooring. The roof is supported by heavy trusses of hard pine, and is covered with the best of Easton slate. The boiler room is completely isolated from the engine and dynamo room by brick walls running to the roof, the only communication between the rooms being through a doorway closed by an iron door. The circuits are led into the building through hard pine timbers built into the wall, glass floor insulators being set into the hard pine, and heavy Clark wire running from the outside of the building to the switch-board directly beneath the point of entrance. The plant consists of three American dynamos, two of 50 lights capacity each, and one of 25 lights, belted direct to the engines—one New York Safety Steam Power Company's 60 horse-power, and one Armington and Sims' 50 horse-power—with Charles L. Ivison's patent adjustable link belts. The boiler is of 100 horse-power, made by E. Hodge and Co., of East Boston, and is fed by a Davidson steam pump, through a National feed-water heater. It is set with the Jarvis patent furnace, and a mixture of Cumberland coal and screenings is used for fuel. All the appliances are of the most approved modern design, and no finer or more convenient station for the capacity can be found. The switch-board—furnished, as is all the electrical plant, by the American Electric Manufacturing Company, of New York—is a model of compactness and simplicity, and enables the man in charge to handle the circuits with great ease, and to make any desired change or combination without stopping the dynamos. This company has a large and prosperous business in East Boston and Chelsea."

THEATRE LIGHTING IN PARIS.—The terrible disaster at the Opera Comique has led in France to a very wide-spread feeling that gas should be at once and finally excluded from the interior lighting of theatres and places of public amusement. This feeling found expression at the last meeting of the Municipal Council in a resolution proposed by M. Emile Richard, and for which urgency was immediately voted. The resolution was couched in the following terms:—"Considering that the employment of gas in the lighting of theatres and concert rooms constitutes a permanent danger to the public, the Council determines that a delay of three months is allowed during which the theatres and places of public amusement of Paris are to substitute throughout their establishments the electric light instead of gas light. At the end of the aforesaid period the public will be forbidden to enter all buildings of this description which have not complied with the terms of this order." In the meantime, the regulations drawn up by the Prefecture of Police for the installation of electric light are allowed to remain in all their original crudity. Our readers will find a transcript of this extraordinary edict in our issue for March 25, 1887, and it will be a matter of some interest to see how the Paris theatres are to be extricated from the predicament in which they are undeniably placed. The Municipal Council will almost certainly confirm the resolution for the compulsory adoption of the electric light, while the unquestionably impracticable character of the police regulations amounts to little short of a prohibition of its use. No doubt the electrical industries in Paris will make the strongest possible protest against the continuance of these absurd restrictions; but in the meantime the police are evidently determined to enforce the edict in all its rigour. The little theatre of Chatelet was closed last week by order of the police for non-compliance with the regulations in the matter of the Jablochkoff candles, with which it has been lit for the past two years. We do not know in what precise point the Chatelet installation was in fault; but it is scarcely probable that the actual risk from the use of electricity could in any case have been comparable with that which exists in any theatre lit by gas.

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 28.)

In the curve given in the preceding chapter a certain value for h was indicated at which maximum work would be performed by the machine, and this was stated to be applicable to one size only.

Although the above restriction is actually imposed by the mathematical facts, the necessities of the designer, who must have some rule in fixing the value of h, and the many simplifications attending its removal, well justify us in treating the depth of winding as a simple linear function.

The best average ratio, β, may be found by calculating such a curve as was given in Fig. 9 for the most usual sizes. We then have in the expression for E,

$$E = Z_1 \,.\, n \,.\, N \,.\, 10^{-6}$$

Taking the radius of the armature R as representing the linear dimensions of the machine, we have $Z_1 \propto R^2$ when the density σ is constant, also under like conditions the magnetic resistance of the system $\propto \frac{1}{R}$.

$$p_1 = Z_1 (K_1 R_A + R\alpha).$$

$$\therefore\ p_1 \propto R.$$

In a similar manner $z = \frac{p_1}{\rho} \propto R^2$.

$$\therefore\ Z_1 + z \propto R^2.$$

But $$Z_1 + z = \frac{p_2}{K_2 R_F};$$

$$\therefore\ \frac{p_2}{K_2 R_F} \propto R^2;\ \text{also } K_2 R_F \propto \frac{1}{R}$$

$$\therefore\ p_2 \propto R; \qquad \text{thus } p_1 + p_2 \propto R.$$

The total exciting power is thus a simple linear function; but this would not be the case unless h were expressed simply as inversely proportional to R.

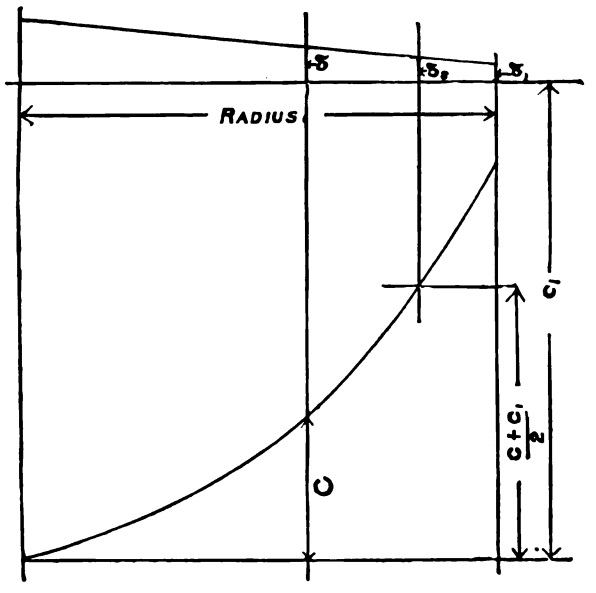

FIG. 10.

The original variation for the output with the linear dimensions may also here be incidentally verified.

Keeping N constant, and expanding the machine in all parts whilst maintaining a constant peripheral velocity, $n \propto \frac{1}{R}$ and $Z_1 \propto R^2$, thus $E \propto R$; under these same conditions it was shown in the previous chapter that $C \propto R^{\frac{3}{2}}$, thus $E\,C \propto R^{\frac{5}{2}}$.

Similarly, keeping n constant, $E\,C \propto R^{\frac{7}{2}}$, which were the two results obtained from the original equations.

Since P, the exciting power, $\propto R$, and the current, $C \propto R^{\frac{3}{2}}$, it is obvious that the length of the magnet cores must vary as $R^{\frac{2}{3}}$; the product $C\,l$, to which P is proportional, where l is the length, will then vary as R.

The fact that this variation in the length of the cores will destroy the equation for the magnetic resistance introduces a differentiation into this problem, but one so unimportant that it may be safely neglected.

It is frequently found convenient to make the depth of winding at the inner radius of the armature considerably greater than on the outside. In those machines in which the sides of the armature are embraced by the pole-shoe it then becomes somewhat troublesome to calculate the mean value for δ.

The following simple geometrical construction will be found very useful in making this determination. The radius R is first set out horizontally; on this the two verticals δ and δ_1 are known, and the line joining their extremities is accordingly drawn and produced to the origin. Then, since the magnetic conductivity of an air space is proportional to the ratio

$$\frac{\text{cross section}}{\text{length}}$$

the elementary conductivity will be represented by

$$\frac{R}{\delta}$$

the values of which are plotted on the lower curve. The point of mean conductivity between the values c and c_1 is projected to the upper figure which gives the corresponding value δ_s, which may be taken as the mean length of *side* air space. The true mean is then found at once from the relative areas of the top and side surfaces of the shoe.

Hitherto it has been assumed that the full E.M.F. calculated from the speed and strength of field could be obtained. This, however, is not strictly true, excepting under ideal conditions.

In the first place an error, which, however, is really infinitesimal in ordinary machines, is made in the assumption that the E.M.F. is expressed by such an equation as

$$E = Z \,.\, n \,.\, N \,.\, 10^{-6}$$

which does not give any indication of the integration which would be required to express the sum of the different velocities of line cutting of the various coils. The reason that such simple treatment is justifiable is because in ordinary machines the coils are so close together, side by side, around the armature, that practically the E.M.F. in each half of the armature is the automatic integral of every different velocity of line cutting, and the error is in reality only that which results from treating the field as uniform throughout the angular space occupied by a single wire. Although practically correct for ordinary dynamos, this equation could not be used for such machines as the Brush arc light dynamo.

There is, however, a real modification in the E.M.F. due to self-induction. Self-induction generates an E.M.F. in a circuit by the magnetic disturbances due to fluctuations of current within itself, that is to the increase or decrease in the number of its own lines of force. Since every circuit contains at least one closed loop, it is evident that the magnetic lines sheathing the conductor must in their formation or extinction produce a corresponding increase or decrease in the number of lines contained therein. The E.M.F. thus generated is, by Lenz's law, counter to the impressed E.M.F., and is measured at any instant by the rate at which the lines are increased or diminished, and the mean E.M.F. during the time T, in which the total number of lines are enclosed or extinguished, is the surface integral of all the values taken at each element of the time T, divided by T.

The above integration can only be made when the curve of the velocity of change is known, and this depends entirely upon the conditions of the circuit.

The reversal of current at the collecting points on the commutator is accompanied by (1) an extinction of the lines due to the exciting power of the particular coil, or section of coils, under reversal, and (2) by the birth of a new set of lines in the opposite direction; both these changes oppose the flow of the impressed lines, and may therefore be looked upon as actual lines flowing in the opposite direction.

Digitized by Google

Viewing the matter in that light and neglecting the effect of hysteresis, it would seem that the same exciting power would be necessary to cancel a line of force as was required for its production. The fact, however, that a large proportion of these lines must close through the air space just over the collecting point would vitiate the above reasoning, and we are therefore unable to state in numerical terms the magnetic resistance offered to the passage of the back lines. The same difficulty is confronted on endeavouring to express the numerical value of the average current which excites these lines, because the logarithmic function which gives the curve of the stability of a current in terms of the resistance and time also involves the coefficient of self-induction of the circuit. This coefficient is merely the number of lines which would pass through the circuit with unit current, but, with our present knowledge, it cannot be determined direct from calculation.* We know, however, that Z_L, the back lines, can be expressed as the product of the average current into the number of coils through which it is passing, divided by the magnetic resistance of the system. Now the number of coils engaged in reversal is proportional to $\frac{N}{S}$, where S is the number of parts in the commutator; thus with constant speed the counter E.M.F. $\propto \frac{N C_a}{S R_L}$, where C_a = the average current, and R_L = the magnetic resistance to the back lines. It will be seen at once that the above expression vanishes at saturation point of the armature core, as R_L would then be infinite; the importance of making the commutator with a great number of segments is also apparent.

(To be continued.)

INCANDESCENT LAMP MANUFACTURE.—XVII.

BY J. SWINBURNE.

Exhausting Continued.

The lamps to be exhausted are sealed to a branch tube, so that three or four are pumped at the same time. The sealing-on tubes left on the lamps by the glass blowers should have thick walls, otherwise it will be difficult to seal the lamps on. To make a good joint the lamp is held in a slanting position, so that the end of the sealing-on tube touches the end of the branch tube at one side. The tip of the flame of the blowpipe is then directed so as to play on the whole of the edges of both tubes till the glass begins to fuse. The lamp is then moved into a vertical position so that the two tubes are sealed together; the lamp is then raised so as to draw the joint out a little. This is necessary, otherwise the joint would probably crack. It requires some little practice to seal on nicely. A beginner may blow into the joint by means of a piece of rubber tube from his mouth to the branch tube. There is always an extra branch left, and when all the lamps are sealed on this is drawn out to a fine point. When the lamps are finished this fine point is broken off. If the vacuum in the pump were broken roughly by breaking off one of the ends of the branch tubes, for instance, the rush of air would take the phosphoric anhydride round into the pump. This extra tube can then be used for a rubber mouth tube. Before starting the pumps care should be taken that the joints are good. If they leak much it will of course be noticed at once, but if there is a small crack it may be found out by the pump taking a long time and not finishing the lamps properly even then. If a small crack is discovered after the pump has been running for some time it may be touched with the finger wet with silicate of soda. If the joints are clumsy the lamp may crack off, and if this happens when the pump is working the phosphoric anhydride will be taken round into the pump, and the whole will have to be dismounted and cleaned. Between the branch tube and the pump one or two phosphoric tubes are inserted to dry the air from the lamps. The blowpipe used for sealing on is the cause of much moisture, and blowing into the branch tube in sealing causes more. The bulbs are also generally wet inside when they come from the glassblowers. When the lamps are sealed on and the pump started, the air taken down by the pump shafts greatly diminishes, till there is a rattling noise. If the pumps are now allowed to run for a long time it will be found that the vacuum after a certain point does not seem to improve. This is because the inside of the bulbs still contain a great deal of air and moisture which is condensed on the glass and in the carbon. This comes off gradually, and will, in fact, continue to come off even after the pump has been running for a week. This difficulty is overcome by heating the lamps or running them on the pumps. Leads are arranged so that the lamps can be run a little brighter than their normal power. The writer has used a water resistance for each lamp, so that each could be brought to the right temperature. The water resistance consists of a tin bottle with movable wires through the cork dipping into a solution of caustic soda. In order to heat the glass thoroughly the heat is kept in as much as possible by means of asbestos caps put over the lamps. The lamps and the branch tubes may be placed inside a sort of oven of asbestos or some such non-conducting material. It will be found that on heating the lamps the pumps will at once begin to take down air again, and the rattling will cease for some time. After a little it will again commence, but soon the pump will take down no more air. The lamps are then finished and may be sealed off.

The practice of running the lamps on the pumps is almost universal among lamp makers; but the writer thinks it is a mistake, and has long ago abandoned it. It is generally supposed that the gas which appears when the lamps are run on the pump comes out of the carbon; but it seems probable that practically the whole of it comes off the glass which is heated by the carbon. Carbon, when it has been well flashed, has, as already stated, very little power of occluding gases, this power having been destroyed at the high temperature needed for depositing hard grey carbon. It is, of course, well known that glass condenses considerable quantities of gas on its surface. The writer has made numerous experiments, and finds that if the lamps are heated enough by external means it is quite unnecessary to run them on the pumps. If the vacuum of one of these lamps is tested after it is sealed on the pumps it will not be found to alter when the lamp is run. If the joints are made by deposition of carbon under benzole, or of merely carbonised cement, they may contain some hydro-carbon, or may occlude gas, and it may then be advisable to run the lamps on the pumps. In the writer's lamps the joints are made by deposition from gas, so that there are no such troubles.

Though the Sprengel pump is generally regarded as infinitely superior to the Geissler for high vacua, the writer believes this to be a mistake. Nevertheless if a Geissler pump is badly designed or badly worked, its results are not nearly so good as the Sprengel pump. Before arriving at this conclusion, the writer tried many experiments. He made an experimental pump, consisting of a Sprengel and a Geissler connected to the same lamps. In all cases the Geissler gave the best vacuum. The Sprengel could be worked till it took no more air down, and the Geissler would always continue to take out air. Many different Sprengel shafts, with jets of different sizes, were tried to make sure, but the result was always the same.

To get such results from a Geissler pump two things are necessary. The bulb of the pump must be kept perfectly dry, and the valve must be so designed that it is opened with the least pressure. Figure 16 is a diagram of the writer's pump. It consists of a bulb, A, on a long stalk, G, which passes through an airtight stopper nearly to the bottom of the bottle B. The bulb is drawn to a point at the top, and the tube is enlarged into the little bulb at C. It is again contracted where it joins the valve tube D. From the top of D there is a tube to the globe E, which communicates with the vacuum tube F; H leads to the phosphoric tube I, and J leads to the branch tube on which the lamps are sealed.

* Recently Profs. Ayrton and Perry have constructed a most interesting instrument, called by them secohmmeter, for measuring co-efficients of self-induction. There would be some difficulty in using it in connection with dynamos, however, on account of the necessity of obtaining the proper working condition of saturation.

Digitized by Google

Ten or twelve pumps are mounted on each table. The pump tables are long and narrow, and of a convenient height for the operator. The tables are away from the walls, and the pumps are fixed to the backs. This is to make them easy of access for repair. The pumps are worked by girls, but, though it is easy to train girls to work the pumps well, it is impossible to get them to understand the principle enough to repair their own pumps. The repairing and replacing is therefore done by men, or preferably boys, but each pump must be accessible without interfering with the working of the other pumps. Each girl looks after five or six pumps. A careful lad can keep twenty or so in order. A set of pipes runs along the front of the table for gas, compressed air for raising the mercury, compressed air for the blowpipes, and vacuum for starting the pumps. The operator has then the whole under control from the front. When the lamps are sealed on, the pump is started by opening the tap L, which is connected with the vacuum pipe F. Communication with

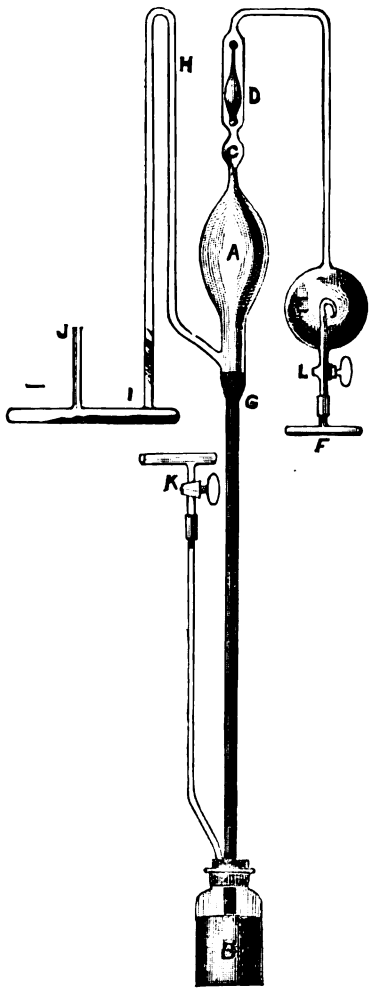

Fig. 16

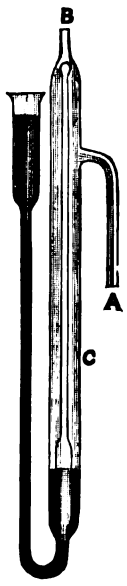

Fig. 17.

E is made through a bent tube drawn fine. This is bent so that any globules of mercury that are drawn over into E may not be taken into F. It is small, so that there is not a sudden rush of air through the phosphoric tube, and so that the vacuum in F is not too much reduced, as if the vacuum in F were broken and some other pump on which the lamps were nearly finished were at the moment connected to F, the vacuum might be spoilt, as the valve in D will not always hold against pressure. Though the tap L is shown diagramatically just under E, it is really at the front of the table. When the vacuum in the pump and lamps is about half an inch the tap L is shut and K is opened. This communicates with the intermittent air pressure. When A is exhausted the mercury rises to the level shown in the diagram. When the pressure comes on it rises quickly past the mouth of the tube H till it comes to the first contraction. The pressure is enough to raise it about half-way up D. It therefore rises slowly to this point and the valve floats in it. The pressure is then removed, and the mercury falls; but the valve closes before the mercury has all run out of D, so that the valve is sealed by mercury. When the mercury uncovers the end of H air from the lamps runs into A. When the mercury rises again this air is accumulated in the little bulb C till it has enough pressure to lift the valve and bubble through. It takes little to lift the valve, as it is exhausted on both sides. The little bulb C is to prevent the mercury rising and hitting the valve with a sharp tap when the exhaustion is nearly complete. If it were allowed to do so, any air that there might be would be compressed into a small volume at the moment the valve was opening, and would then stick against the glass instead of being carried through. As it is, the contraction below C breaks the shock due to the inertia of the rising mercury, and it then rises slowly as there is little available pressure. The whole success of the pump depends on the valve arrangement. The great thing is to avoid water vapour; it condenses against the walls of the little bulb C, and remains there till the valve is closed. It then expands again and fills A. If the vacuum in E is kept very good, water vapour will always have enough tension to lift the valve. When the vacuum in the lamps is nearly complete the pump will only take out a very small bubble of air each time. When the valve rises it does not rise straight, and the lower end follows the curved side of the valve tube a little way and then leaves it, and it leaves the air sticking against the side. Thus the air taken out by each stroke can be seen. The pump never shows a perfect vacuum—that is to say, it always takes out some air every stroke.

When a Sprengel pump stops this pump shows a vacuum of about one in a million, and if worked for some days it still shows a pressure of about one in five millions, according to the usual determinations of vacua. In starting a new pump it is often necessary to heat the shank G by means of a Bunsen burner, as bubbles are otherwise apt to come off the glass, and rise and spoil the vacuum. The phosphoric tube I is made long at one end for ease in refilling. When the phosphoric anhydride is used the tube is replaced. The long end is opened, and the tube washed out, dried, refilled, and sealed again. This is repeated till it gets too short.

A little cotton wool may be put in the tube H, so that if the lamp breaks off the air does not carry the phosphoric anhydride round into the pump with a rush. The compressed air is supplied by a small air compressor, which delivers into a reservoir. This reservoir is connected with the various pumps through a three-way tap, which is worked by a sort of adjustable cam arrangement, driven by any convenient shaft. The tube K is thus alternately supplied with compressed air, and connected with the atmosphere. The time the pressure is on is regulated by the cam arrangement, and the pressure is regulated by a sort of blow-off valve, which is shown in Fig. 17. The vertical chamber C is connected by the tube A, with the pressure reservoir in the engine room. The pressure is balanced by the head of mercury in the other limb. If the pressure is too great, a glass float connected with the glass rod and valve falls and opens the outlet B. The compressor is made to give rather more air than is needed, so that the pressure is controlled by the valve. This arrangement is placed in the pump room, so as to be accessible. The pressure is regulated by the amount of mercury.

The writer's pumps have the advantage of extreme simplicity. They are easy to make; in fact, they can be made by lads, no part demanding skilled labour. They are easily worked, and the mercury is kept clean; in fact, it never seems to get the least tarnished, and a pump goes on for months without needing cleaning. The lamps are not run on the pumps, but are strongly heated externally. The branch tube and the lamp are placed inside a sort of oven. This consists of a cover made like a large tin top hat. The walls of this are double, the space between being packed with slag wool. Each cover is suspended from the ceiling, a counterweight and pulley being arranged so that when the lamps are sealed on the cover is drawn down over them. It then sits on a tin base, which is

Digitized by Google

made in the same way. The cover has three short legs, which keep it half an inch off the plate. The tube J is led so as to come in under the cover and rest on the plate; it then rises to the lamps. There is a hole in the centre of the plate, through which a Bunsen burner passes, the plate being raised from the table so that the top of the burner is a little above the top plate. There is a small hole in the top of the cover. A very small flame heats the lamps strongly enough, and so even and gradual is the rise of temperature that exhausted lamps will sometimes collapse gradually without breaking. The writer has seen lamps in which not only the thin parts of the globe were folded into contact, but even the thick ends where the stems were sealed in were flattened. Generally, however, lamps inplode, or burst inwards, when too strongly heated on the pumps.

LITERATURE.

Factory Accounts: Their Principles and Practice. A Handbook for Accountants and Manufacturers. By EMILE GARCKE and J. M. FELLS. [Crosby Lockwood and Co., 1887.]

Writing with some amount of experience with regard to accounts, we must confess that this work of Messrs. Garcke and Fells seems to us to be one of the most important ever published dealing with these matters. These gentlemen have treated the subject from the standpoint of the factory, as practical men speaking to practical men, and not, as has been too often the case, as schoolmasters to schoolboys. The authors give us valuable information relating to business accounts. The schoolmasters give information to enable the schoolboy to pass an examination, the examiner generally knowing about as much of the practical work as the schoolboy himself. It will obviously be impossible without writing a mongraph on the subject to deal at length with a work of this kind. We presume the text of the author would be to show that in all factory accounts there must be independent checks for every transaction, and that these checks must be such as cannot be tampered with to the detriment of the owners. The sermon they have preached upon this text is an admirable one, and the lessons to be derived are valuable. Specimen headings for the various books are given. Each point as it arises is clearly considered, and its bearings upon the main question shown. We are quite sure that there is scarcely a limited liability company in existence which keeps its accounts satisfactorily. The temptation to add to capital and to minimise depreciation is a phase of human nature that so long as companies exist will not be found wanting. Messrs. Garcke and Fells very clearly lay down the features of business which determine depreciation, and they insist on periodic valuations. We could wish that every manager or managing director of every company would carefully consider all that has been said by the authors, and as their views seem adapted to promote financial soundness, we trust they will be more extensively followed in the future. Whatever influence this book may have, the commercial community is under a heavy obligation to the authors for having so carefully analysed the system of factory accounts and so clearly put the analysis before the public.

ELECTRIC LIGHT ILLUMINATIONS FOR THE JUBILEE.

Although the electric light will make a fairly conspicuous show in London on the night of the Jubilee, yet, owing in large measure to the comparatively short notice which has been given, many firms have already had to close their books, having exhausted their available stock. The following account will, we believe, be found to include the most important of the installations which are to be carried out within the metropolitan area:—

Conspicuous among the illuminations in the City will be that of the Stock Exchange, which has been entrusted to Messrs. Woodhouse and Rawson. The front of the building facing Broad-street will be brilliantly lighted up by rows of incandescent electric lamps following the outline of the structure. Above these will be placed a couple of devices forming the letters "V. R.," composed of lamps of variegated colours, the whole being crowned by two arc lights of intense brilliancy. The same firm have also undertaken to illuminate the outside of the warehouse of Messrs. Fred. Huth and Co., of Tokenhouse-yard. A similar idea will be carried out here, the outline of the building and portico being followed by rows of incandescent lamps, while each side of the doorway will be flanked by the letters "V. R," formed of coloured lights. Messrs. Woodhouse and Rawson have in hand several other installations of smaller dimensions at private residences in the West End.

Messrs. Laing, Wharton and Down will testify to their own loyalty on the occasion by an illumination of arc lamps in front of their offices on the Holborn Viaduct. In consequence of the drain upon their plant by the requirements of the American Exhibition, which this firm are now lighting by electricity—they have been obliged to refuse many orders for installations in different parts of the City. This firm are making arrangements for illuminating the *façade* of the Temperance Provident Insurance Offices at London Bridge, on which twelve powerful arc lamps will be displayed. They have likewise contracted to supply the new premises of Messrs. Pears, soap manufacturers, in Oxford-street, with ten lamps of the same kind.

Messrs. R. E. Crompton and Co., of Queen Victoria-street, have secured some orders for minor installations in the City and elsewhere. They have also supplied the following orders in connection with the illuminations:—One dynamo and six arc lamps for use at Dorking; one dynamo and six arc lamps for use at Hampstead; 25 arc lamps to Messrs. Verity for use on a triumphal arch at High-street, Kensington; 10 arc lamps to the Edison-Swan Company; and 50 incandescent lamps for Messrs. Barclay's bank. The majority of the arc lamps will be of large size, giving from 5,000 to 11,000 candle-power. We understand that Messrs. Crompton have found that the demand for arc lighting has far exceeded their expectations, and it has not been possible to accept all the orders received.

It will, perhaps, be in the region of clubland, however, that sightseers will find most to gratify the eye in the matter of outdoor lighting. There the most extensive preparations are being made to give unstinted expression by electric and other illuminants to the depth of the national attachment to the Throne. The members of the Junior Carlton Club, who of recent years have claimed an almost exclusive monopoly of this particular virtue, are determined for once to out-distance their neighbours in point of light and leading, for they promise to have one of the largest, if not absoletely the largest, individual electric light installation in the metropolis. Messrs. Verity and Sons, of Covent Garden, have been commissioned to carry out the work, which will consist, among other attractions, of no less than 28 arc lamps of 2,000 candle-power each, distributed artistically over the side and front elevation of the building. The same firm have also the contract for lighting the Grand Hotel at Charing Cross, for which they have designed some pretty and appropriate devices in incandescent lamps. They have besides booked a number of smaller orders for private houses in and near London.

The new Gülcher Electric Light and Power Company have had an accretion to their ordinary business on account of the Jubilee celebration; but they have chiefly confined their attention to the execution of provincial orders, amongst others being installations for Southampton, Herne Bay, and Ashford. Besides supplying the Crystal Palace Company with thirty arc lamps of 2,000 candle-power for lighting up the grounds, the Gülcher Company are responsible for the electrical apparatus which is to be used for the firing off of a salute of twenty-one guns from the band stand in front of the Palace on the arrival of the Prince of Wales, who has promised to attend the rejoicings there. The company have also the contract for the illumination of Winchester Cathedral with a 10,000 candle-power Gülcher projector.

The Anglo-American Brush Corporation are providing the following:—At the Institution of Civil Engineers, Great George-street, an inscription covering the whole front of the building, formed by over 500 ten candle-power glow lamps. This will be a complete temporary installation, there being no available engine or dynamo on the premises. At the Drapers' Hall, Throgmorton-street, an illuminated inscription and tracing of some of the lines of the building in lines of light will be shown, some 160 glow lamps being used. These will be taken from the permanent installation supplied to the Drapers' Company by the the Anglo-American Brush Electric Light Corporation last year. Lord Thurlow's house in Chesham-place will be similarly illuminated with about 120 glow lamps, and Mr. Lampson's house in Pont-street, Chelsea, with about the same number, the current in both these cases being supplied from permanent installations supplied by the Anglo-American Brush Electric Light Corporation.

Messrs. Faraday have been for some time busy in responding to the many demands made upon them for electric light decorations for a number of important buildings in the West End. Messrs. Collinson and Lock's establishment in Oxford-street, as well as the Royal Institution, Albemarle-street, have been each fitted with electric lighting apparatus, and the latter especially promises to give a display worthy of its name and traditions.

THE JUBILEE OF THE TELEGRAPH.

PRESENTATION PORTRAIT OF FARADAY.

Our readers know that the present year of grace is not only the Jubilee of the accession of the Queen, but also of the introduction of the Electric Telegraph. The most prominent Electrician of the period—we might say of the century—was Michael Faraday, and we purpose giving with our next issue (as a Supplement) a Steel Portrait Engraving of this illustrious representative of English electrical science.

OUR AMERICAN COUSINS.

The meeting of the British Association on the American continent in 1884, and more particularly the visit which many of the members paid to the States on that occasion, have been not merely conducive to good relations between kindred races but productive of fruitful results to the community of science. In May of that year the American Institute of Electrical Engineers came into existence, and it was honourably represented at the Association's gathering at Montreal in the following August. A month later the Association furnished representatives to attend the Electrical Exhibition at Philadelphia. There is little doubt that from one of these points the society which in America corresponds nearest to our Society of Telegraph-Engineers and Electricians practically dates its active career; and equally probable is it that the English visitors contributed to make its beginning a hopeful one. At all events, the two societies are working on similar lines and for the same ends; and we may confidently assure the younger society of the sympathetic good wishes of its elder cousin in England. A more substantial proof of goodwill would, we have no doubt, be forthcoming should the American Institute find it necessary to ask for it in the shape of subscriptions to their building fund—or to speak in the American manner, their "Permanent Quarters'" fund. If we hope that no such appeal may be necessary it is simply because we should prefer to see the money subscribed on American soil in proof of America's sincerity in patronising—to quote the native language again—"the development of Electric Arts."

The position of the British and American societies is identical in respect to their indebtedness to an external society—that of the Civil Engineers in both cases—for their places of meeting. The former, it is true, possesses a separate establishment liberally endowed, and already possessed of offices and reading room, with probably the finest electrical library in the world. At these premises, too, are held the Students' meetings, which have been only recently started, although the admission of students to the privileges of the Society dates many years back. We incidentally mention this fact for the benefit of our American friends, some of whom seem to have been much exercised on a point of dignity by a proposal to add to their roll a class of "Juniors." These juniors are spoken of disparagingly as boys who have no serious interest in the objects of the Society. We are naturally diffident in offering a common-sense suggestion to our hard-headed transatlantic relations, but it does seem to us that were they to call these "boys" *Students*, and take steps to make them live up to it, the question of dignity would be satisfactorily disposed of, as it has been here.

Except for the purposes above named, however, the English Society of Telegraph-Engineers and Electricians has been dependent during the whole of its lifetime, dating from 1878, upon the generosity of the Institution of Civil Engineers for the use of their splendid theatre, in which the Society's fortnightly meetings during the spring and winter months of the year are held. The American Society, on the other hand, although only three years old, aspires already to own a separate "house" all to itself, and the cost of which is to be $30,000. The sum is not extravagant, and the charge for maintenance, exclusive of personal service, is estimated at only $2,000. Of the prime outlay it is thought that a third can be collected, the remaining two-thirds being borrowed at 4 per cent. interest, which is included in the figure mentioned for maintenance. The scheme is a bold one, considering the present numerical strength of the Society; but the Council are confident of largely augmenting its members, and more especially when it enjoys the advantage of possessing an establishment of its own "where men engaged in the same pursuits could freely interchange ideas and afford each other mutual encouragement." A library is also in contemplation, the general plan being "to establish an institute of such repute that it will become the natural custodian of valuable collections of books and apparatus which are now so frequently scattered when their owners pass away."

In commending this scheme to the favourable attention of our readers we cannot abstain from noticing the eminently sound and practical character of the American Institute of Electrical Engineers. Casting a glance over the list of papers brought under its notice between May, 1884, and the corresponding month of the present year we are struck by the invariable utility of the subjects dealt with; and this impression is confirmed by such of the discussions as have been reported in American journals coming into our hands. But we have also been struck by the long-windedness of the speakers. It seems to

Digitized by Google

be the custom of American electricians to invigorate their bodies during the session by frequent social gatherings, which take the form of dinners, and, if we may judge by what happened at the Philadelphia Electrical Exhibition, to obtain relaxation for the mind by indulging in infinite jest when the serious business is ended. These customs now recur to our memory in this relation, as explanatory of national traits which we had never been able to account for before. In one of the grotesquely humorous primers published at the fag-end of the Exhibition there occurred the following description of electric lights, which, it was said, were of two kinds, namely, "Our kind, and the other fellow's kind. Our light is much brighter than the other fellow's light. The other fellow's light is surrounded by a cloud of non-luminous verbosity." Now, irreverant and unseemly as this sort of caricature may appear, it is not wholly useless or impertinent. For simple verbosity our American fellow-workers—or, more correctly, speakers—incontestibly carry off the palm. When we take up an American technical paper we have always first to wade through or skip an exhausting oration. This we now very gladly attribute to the dinners. But for English verbosity of the "non-luminous" kind we have only one explanation to offer, namely, the absence of that humorous faculty which is ever alert in the native born American. On this side of the water we should be saved from many a non-luminous infliction if we were equally endowed with the sense of the ridiculous; and it is probably the Americans' superiority in this respect that has kept their Electrical Engineers strictly to the practical aspect of their profession, so soon as the preliminary orating has been got over. We have not obtained, and we hardly expect to receive from America any supremely valuable contributions to our stock of mathematical and scientific knowledge; but she has supplied us with much that is in the highest degree valuable in the domain of practical and applied science; and we are the more thankful for it, because its diffusion here may counteract our tendency to wander into fields of abstract speculation. The American Institute of Electrical Engineers has a very useful career before it; and the venture on which it is just now embarked deserves, and will receive, the best help we can give it.

CORRESPONDENCE.

"EDWARD DAVY."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of June 10th Mr. J. J. Fahie inquires if I am a debtor to E. Davy, with reference to my automatic accumulator switch. I beg to say that, never having seen a copy of the "History of Electric Telegraph," I never heard of E. Davy until this day. I hope Mr. Fahie will forgive my ignorance, which is due, no doubt, to my not having read his work.—Yours, &c., W. E. WILSON.

Daramona, Streete, Co. Westmeath, June 12th.

THE REGULATION OF SERIES TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Rankin Kennedy, in your last issue, says that the notices you have given of our work do not contain any actual practical results of careful tests to ascertain the losses in the induction coils. This is so; but we are at present, and have been for some time, engaged on these and similar tests, the results of which we shall shortly make public. But it would seem from Mr. Kennedy's letter that there really is no need of any such tests, for he goes on to say our figures are no doubt nearly correct. We may take it, therefore, that the error is not 100 per cent. But, Sir, we say that the loss in a coil is ·6 per cent., therefore Mr. Kennedy will admit the true loss is not double this, or 1·2 per cent.; and if he admits this, what need is there for elaborate experiments? Here, however, he falls into the most extraordinary error, for he says that the error is no doubt negligible when one coil is used, but if 1,000 coils were used the economy would be effected. Surely if the error is ·6 per cent. (an outside figure according to his showing) for one coil it is ·6 per cent. for a thousand. He might as well say that a large dynamo is less economic than a small one because more power is absorbed in the armature of the larger machine!

Mr. Kennedy also says that the core in all coils becomes hot. We have found that ours never get hot, and some never even warm.—Yours, &c., SHARP AND KENT.

Connaught Mansions, Victoria-street, S.W.

ARC LAMPS AT THE NEWCASTLE EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Sayer writes in your issue of the 3d inst. as if the report that the "Diamond" arc lamps at the Newcastle Exhibition were unsteady because they could not be regulated prior to the opening night in consequence of the contractors being late for the work was a correct one. To let this pass would not be fair to Messrs. Woodhouse and Rawson. On account of the contract having been undertaken a long time after the other contracts were settled there was but little time left to manufacture and put the lamps up. These are run four in series, and grouped four in parallel with each other, and distributed over 31 acres of ground; consequently, as there was no time to run the lamps before the opening night, in several instances the lamps were coupled up wrongly, hence the unsteadiness. After the first night the connections were properly made, and only six lamps had to be at all adjusted, notwithstanding they were made in a great hurry and sent up to Newcastle in pieces. Since then the lamps have been absolutely steady.—Yours, &c., J. E. STEWART.

Industrial Exhibition, Newcastle on-Tyne,
June 9th, 1887.

ELECTRIC LIGHTING ON SALVAGE STEAMER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sure your readers will agree with me when I say that letters sent for insertion in *The Electrician* should at least lay claim to be fairly accurate, especially when written by those offering information on the subject of electric light installations.

The letter in your last issue signed "F. Hanson Perry" is in every particular so very far wide of the actual facts that I feel compelled to write this letter, and to ask you, with your usual impartiality, for its insertion.

The salvage steamer "Hyæna" was not fitted by either Messrs. Siemens and Co. or Perry and Company (Limited), but by the late firm of Perry and Cox, and the work having been done under my supervision and instructions in every detail from drawing up the tenders to lighting the first lamp, is my excuse for trespassing on your valuable space.

The dynamo is not a 4,200-watt machine, but a 6-unit (65 volts 92 amperes) compound; built by Messrs. Paterson and Cooper to run within 1,000 revolutions, it does its work effectually at 870. This machine is driven by a Gwynne invincible engine, and both engine and dynamo have worked admirably since being started last year. Instead of being 30 incandescent lamps there are only 10, no more being required.

The two Pilsen arc lamps take 28·26 amperes each, their resistance including the resistance in outer circuit to help them to feed being 2·3 ohms each. Your readers will see that 3,000 candle-power is below the usual estimate for such a current.

Regarding the specially designed switch-board (?) this is simply the ordinary one requisite for the installation, including the necessary cut-outs. As to the alleged difficulty of working arc and glow lamps in parallel, I will leave electricians to judge

Digitized by Google

if there exist any. The burning of the arc lamps is simply perfect; but I regret to say the 100 candle-power diver's lamps have not proved the success anticipated, mainly owing to the frequent breakages of lamps and glasses.

In conclusion, I may say that this small installation has again proved the vast utility of the electric light on board ship.—Yours, &c., CHAS. W. COX.

50, Bedford-street, Liverpool.

THE ELECTRIC LIGHT FOR FISHING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having been with Mr. Perry during the fishing experiments he mentions, I think his statement calculated to mislead my fellow readers.

I should therefore like to say that the shoals of fish spoken of as swarming round the lamp resolved themselves into a solitary eel. No doubt fish, when near, would be attracted by a light, but exaggeration will do no good to the electric light or those interested in it.—Yours, &c.,

FREDERICK G. ROBINSON.

83, Spencer-street, Liverpool, June 13th, 1887.

THE LIGHTING OF THE GLASGOW TUNNELS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My letter to you of June 3rd seems somehow to have annoyed Mr. Carswell, of the North British Railway Company. If that company gave no preference to people who offered them valuable plans they are not singular in that respect, else there would have been some faint appearance of reason in Mr. Carswell's opinion, that the latter part of my letter had nothing to do with estimates; and if Mr. Carswell invented and patented one of my proposals, the fact illustrates another trade trouble, that as it is impossible to patent all the working methods which occur to those engaged in a new business like electrical engineering, the monopoly of each speciality becomes in the end the property of the man who first gets, or knows that he can get, an order for it.

The prices given in "A. and M.'s" letter to the railway company were only intended to give a general idea of the comparative cost of the various methods of lighting which they proposed, and I was quite prepared to have taken measurements and given exact prices and mechanical details if asked. I was not asked.

"A. and M.'s" letter to the company, however, seems to my mind to be fairly capable of conveying to the average practical mind that they proposed to supply current from a stationary engine and dynamo to the fitted trains as they passed through the tunnels. I suppose that Mr. Carswell had not at that time conceived his plan, or surely he would have at least suspected that they were on the same track, and would not have allowed some weeks—or was it days?—to elapse between receipt of "A. and M.'s" letter and his visit to his patent agent. The fact that accumulators were also named as an alternative method should have made it evident that they did not propose to use them in this method. The £800 was a rough guess at the cost of dynamos, conductors, contact rails, &c., for all the local tunnels, and I still doubt if these could be supplied and fitted in such a manner as to have little loss through leakage and none of that wavering of light which is at present complained of for very much less money. As to the £4 being sufficient for fitting carriages. The North British Railway Company, it seems, have had 64 carriages fitted by one man in a "gradual" manner in six months, or at the rate of about 2½ carriages of four to five compartments each per week. From the list of articles which "A. and M." do not make supplied by Mr. Carswell—some of which articles they do make, by the way—I infer that the company bought their material in a highly disconnected form, so that this "only one man employed in the work" must have made up the lanterns, the broken lamp shunts, fusible cut-outs, contact roller arms, &c., &c., and, indeed, I would not be the least astonished to learn that he had laid the permanent rail also, and made the switches, measuring instruments, and other appliances, which ought to be there if they are not, and which were not included in Mr. Carswell's list of material. Railway engineers are famous for enterprise; but I never can understand how it is that when they undertake a little electric lighting they are always able to pick up an idle workman or find some one among their linesmen who can do the work in a fourth of the time which would be required by workmen who are constantly engaged in such work, and who have all suitable appliances at hand. But suppose £1 per carriage was spent in wages and only one pair of contact rollers was used for a train and only one lamp for each compartment, as I would prefer to do, or perhaps one good lamp between two compartments, then the £4 would not be so very far out, although it would be easy to do the work more handsomely if the railway company could be persuaded to authorise the expense. But these details are of no public interest, and I will not trespass further on your space.—Yours, &c., J. M. M. MUNRO.

136, Bothwell-street, Glasgow.
June, 1887.

[This correspondence must now close.—ED. *E.*]

THE TELPHER LINE AT GLYNDE.

The telpher line at Glynde has now been in operation for a period of over two years, and the time has certainly arrived when the question as to the success or non-success of this system of transport should receive a final answer. The question is admittedly one of no slight importance. If telpherage can be demonstrated to be both technically and commercially practicable under the conditions of everyday service, it is not too much to assert that "the resources of civilisation" will have been appreciably widened, while the electrical industries will be materially benefited to an extent which no one can at present foresee.

But is the Glynde line a success? So little definite information having appeared in the public prints on the subject it is natural that remarks of an unfavourable character have not been altogether wanting. When, therefore, we received an invitation from the Telpherage Company to "come and see for yourselves what we are doing at Glynde," we did not hesitate—notwithstanding the torrid heat of the season—to undertake the expedition. Arriving at Glynde after two hours' stewing on the London, Brighton, and South Coast Railway, we found the genial engineer of the Telpherage Company (Mr. C. S. E. Crakanthorp), who accompanied us upon our tour of inspection. That the Telpher line is by no means in a state of inanition was soon apparent. Scarcely had we crossed the fence by the side of the railway when a gentle rumbling announced the approach of a telpher train. On it came at a perfectly uniform speed over the river, round by the bend at the end of the first field, and on to the loop which brings the skips over the railway trucks, into which their contents are tilted.* To one who has not seen it before, the first sight of a telpher train presents a very singular appearance. The peculiar cat-like way in which the skip in front climbs over the top of the poles and walks steadily over the inclines, while the wire rope sags beneath the weight of the train, is very striking. What is actually being done at Glynde may be summarised as follows:—Three trains are running continuously, each consisting of ten skips, and making on the average about 15 journeys daily. Each train carries rather over one ton of clay, so that the total weight moved is about 270 tons per week. The engine plant and the capacity of the line itself are equal to a service of four trains, so that 360 tons per week could be carried with very little increase on the present working cost. That cost is at present £6 per week, a figure which enables the Telpherage Company to carry out their contract with the Sussex Portland Cement Company, of Newhaven, under remunerative conditions, even at the low contract rate of 7½d. per ton.

We have incidentally alluded to the fact that the trains run

* This part of the line has been completely illustrated and described in previous volumes of this journal.

Digitized by Google

upon wire ropes; it will probably be remembered that the original plans (or more strictly *one* of the original plans) of the inventors of the system (the late Prof. Jenkin and Profs. Ayrton and Perry) contemplated the use of steel rods stretching from span to span. Until experiment had actually been made upon a working scale it was confessedly difficult to determine which of these two methods would prove the better. On the one hand the employment of rods on the "cross-over parallel" system necessitated the use of spans all of the same length, or at least not exceeding a certain length, and there was also the difficulty of jointing and insulation. On the other hand, that system of connection did not readily lend itself to the employment of wire rope owing to the difficulty of securing it to the post-heads. It was therefore determined in the first instance to employ steel rods. The details of the construction of the line, together with the wonderfully ingenious devices for ensuring the safety and regularity of the service, were fully described by Prof. Perry in a lecture delivered at the London Institution, and reported in this journal in February, 1886.

The "cross over parallel" system, beautiful in conception as it is, has, however, one defect, which was pointed out by Prof. Perry in this lecture. Each time that the collecting wheels of the motor passed from one conductor to the other—that is to say at every post—the current through the motor is reversed, a reversal which necessarily entails sparking at the brushes. It remained to be seen how far this drawback would in practice counterbalance the advantages of the system in the matter of economy arising from the fact that only two (inter-crossed) conductors are required for both up and down lines.

After some experience, it became apparent that the motors at first adopted were unsuited to this particular class of work under the then existing conditions, and it unfortunately happened that the gentleman by whom the motors were originally designed was unable at the time to give his personal attention to the matter. We think it right to mention this fact because we are anxious not to give an unnecessarily unfavourable impression as to the merits of this particular motor, which, as Mr. Crakanthorp was himself careful to point out to us, has scarcely been able under the circumstances to receive a fair trial.

At this juncture, however, an Immisch motor was placed upon the line in parallel with one of the older type, and it at once became apparent that the former did the same work with exactly one half the energy supplied—that is, one half the number of amperes at the same volts. It is not, therefore, surprising that the Immisch motor has been finally adopted by the Telpherage Company. The type at present in use has a 4in. armature, weighs 105lb., and develops 1 horse-power running at 1,700 revolutions.

Concurrently with the change of motors it was decided to make such alterations to the line itself as would allow a simple parallel system to be adopted, principally in order that steel wire ropes might be substituted for rods, which were found to have a very much shorter life than had been anticipated. This has been carried out with great success; the steel ropes are $2\frac{5}{8}$in. in circumference, and are anchored to cross-beams buried in the soil, with tightening screws for straining up when required. The alteration necessitated, however, the employment of a second wire on both up and down lines in order to convey the current. This wire, which also takes the form of a steel wire rope of $1\frac{1}{2}$in. circumference, is insulated throughout its length. The current is taken off by a jockey pulley made in copper with wide flanges, and the wire upon which the train runs is earthed throughout, as also is the negative terminal of the dynamo. The system, in fact, has now reverted very nearly to that described in one of the earlier patents of Profs. Ayrton and Perry.

The conditions under which a motor running upon a telpher line is worked are necessarily such as to submit the apparatus to an extremely severe test. The protection which can be given against the weather is very slender at the best.

It is under such conditions that the Immisch motors at Glynde are now working with complete success. This satisfactory result has not, however, been attained without a good deal of painstaking attention to matters of detail both on the part of the Immisch Company and of Mr. Crakanthorp. The Immisch Company at one time sent one of their representatives (Mr. A. Snell) to stay for some time upon the spot in order to study the working conditions as completely as possible. The results now attained will be appreciated from the statement that the motors frequently run for a fortnight without even having their brushes readjusted. The commutators receive a touch of vaseline from the switch man at the end of every journey.

The average E.M.F. along the whole line is 170 volts, there being only a volt or two difference between the engine house and the extremities of the line. The total current taken by the three trains amounts to 20 amperes; but owing to the admirable action of the automatic circuit-closers governing the speed of the trains (a feature which is due to the late Prof. Fleeming Jenkin) it is comparatively seldom that the full current is taken for more than a very short interval. The variations of current between 8, 14, and 20 amperes, as shown in the engine-room ammeter, follow one another in rapid succession. The loss by leakage is two amperes. The governors, it will perhaps be remembered, act by centrifugal force, entirely cutting off the current when the speed of the armature exceeds a certain point. The break is made first on carbon and afterwards on copper contacts. Although the gradients on the line are very slight, the trains sometimes run over 100 yards without taking current. The speed of the trains, as judged by the eye, is remarkably uniform, a velocity of about 4 miles per hour being maintained throughout the whole line, both by empty and by full loads. The trains are started at either end, through a set of resistances, which are cut out in four sections, so that the start is effected with great smoothness.

In the engine house the Ruston and Proctor semi-portable engine and the Crompton compound-wound dynamo both look good for many years to come, although, owing to the continuous variations of the load (through the action of the motor governors), it may be assumed that the work is of a somewhat trying character.

We will only add, in conclusion, that the result of our visit has been to impress forcibly upon our minds the fact that, upon the technical side, telpherage must no longer be looked upon as a scientific toy, but has become a thoroughly practical and efficient system of transport, combining the qualifications of cheapness, simplicity, and certainty—a system which, while not intended to compete with steam for heavy traffic, is yet capable of affording a complete solution of an important class of problems in the industrial development of old countries as well as of new colonies and of semi-civilised lands. We do not, however, anticipate, nor is it on the whole desirable, to see "a boom" in telpherage; but that, under capable management, the business of the Telpherage Company will steadily grow into industrial importance we regard as a certainty.

LE MANS.—The gas light company at Le Mans are preparing to supply electric light from a central station.

THE EQUIVALENT OF ZINC.—At a recent meeting of the Chemical Society a note was read by Lieut.-Colonel Reynolds, late R.E., and Prof. W. Ramsey on the equivalent of zinc. The determination has been made by measuring the hydrogen evolved on dissolving zinc in acid, every precaution being taken to ensure accuracy; the weight of the hydrogen obtained was deduced from Regnault's determination of the density of hydrogen. The zinc used was separated by electrolysis from zinc sulphate purified to the utmost possible extent. The last sample prepared was so nearly pure that dilute acid would scarcely act on it. In all 29 experiments were made. Four experiments had to be rejected; nine were not fully corrected, and therefore were also rejected; the next 11 were considered preliminary, the mean atomic weight deduced from them being 65·2430; finally, five experiments were completed, and the results—free from all known sources of error—obtained as the mean yielded the figure $65{\cdot}4787 + 0{\cdot}016135$.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XLI.

BY OLIVER HEAVISIDE.

Nomenclature Scheme. Simple Properties of the Ideally Perfect Telegraph Circuit.

To explain the word "permittance" that I used in the last Section, I may remark that in stating my views in 1885 in several communications to this journal on the subject of a systematic and convenient electrical nomenclature based upon the explicit recognition of the three fluxes, conduction current, magnetic induction, and electric displacement, proposing several new words, some of which have found partial acceptance, I remarked upon the unadaptable character of the word "capacity." It must be the capacity of something or other, as of permitting displacement. I did not then go further in connection with the flux displacement than to use "elastance," for the reciprocal of electrostatic capacity. The following shows the scheme so far as it is at present developed :—

Flux.	Force/Flux.	Flux/Force.	Force.
Conduction Current	Resistance. / Resistivity.	Conductance. / Conductivity	Electric.
Induction	? / ?	Inductance. / Inductivity.	Magnetic.
Displacement	Elastance. / Elastivity.	Permittance. / Permittivity.	Electric.

Why elastivity? Maxwell called the reciprocal of the permittance of a unit cube "the electric elasticity." By making it simply elastivity, we first get rid of the qualifying adjective; next, we avoid confusion with any other sort of elasticity; and, thirdly, we produce harmony with the rest of the scheme. There are now only two gaps. "Resistance to lines of force," or "magnetic resistance," now used, will not do for permanent employment. Besides the above, there is impedance, to express the ratio force/flux in the very important case of sinusoidal current. Impedance is at present known by various names that seem to be founded upon entirely false ideas. The impedance (which, derived from impede, need not be mispronounced) of a coil is the ratio of the amplitude of the impressed force to that of the current. A coil used for impeding may be called an impeder. The same definition obviously applies in any case that admits of reduction to *one circuit* (even though parts of it may be multiple), *e.g.*, any number of coils in sequence, in sequence with any number in parallel (to be regarded as one), in sequence with a condenser, or arrangement reducible to a condenser. The impedance is always reducible to $(R^2+L^2n^2)^{\frac{1}{2}}$, where R is the effective *resistance*, which is real, and L the effective inductance, or sometimes *quasi*-inductance. It is not necessary to exclude inductive action on *other* circuits, although the heat corresponding to R may be partly in them. As for resistance, it is very desirable to confine its use to the established meaning in connection with Joule's law.

Now let R, L, S and K be the resistance, inductance, permittance and leakage conductance per unit length of a circuit; and let V and C be the potential difference (an awkward term) and current at distance x. We have the following fundamental equations of connection :—

$$-\frac{dV}{dx}=(R+Lp)C, \qquad -\frac{dC}{dx}=(K+Sp)V, \quad . \quad (1d)$$

p standing for d/dt. Observe that the space-variation of C is related to V in the same manner (formally) as the space variation of V is related to C, so that we can translate solutions in an obvious manner by exchanging V and C, R and K, L and S, which are reciprocally related, in a manner.

To fix ideas, the circuit may be the common pair of parallel wires. There is one case in which the four constants are all finite that is characterised by such extreme simplicity that it is desirable to begin with it, especially as it casts a flood of light upon all the other cases, which may be simpler in appearance, and yet are immensely more complex in results. Let

$$R/L=K/S=s, \quad \text{and} \quad LSv^2=1 \quad . \quad . \quad . \quad . \quad . \quad (2d)$$

The number of circuit constants is now virtually three, owing to the fixing of the fourth constant. The equation of V is now

$$v^2\frac{d^2V}{dx^2}=(s+p)^2V \quad . \quad . \quad . \quad . \quad . \quad (3d)$$

or, which is equivalent,

$$v^2\frac{d^2u}{dx^2}=p^2u, \quad . \quad . \quad . \quad . \quad . \quad . \quad (4d)$$

if $V=ue^{-st}$. Since (4d) is the equation of undissipated waves, with constant speed v, whose solution consists of two oppositely travelling arbitary waves, the complete solution of (3d) consists of such waves attenuated as they progress at the rate s (logarithmic). Thus,

$$V=f(x-vt)e^{-st} \quad . \quad . \quad . \quad . \quad . \quad (5d)$$

is the complete expression of the positive wave, if $f(x)$ be the state when $t=0$. Shift the wave bodily a distance vt to the right, and attenuate it from 1 to e^{-st}, and we obtain the state at time t. The corresponding current is

$$C=V/Lv=SvV. \quad . \quad . \quad . \quad . \quad . \quad (6d)$$

in every part of the wave. To express a negative wave, change the sign of v in (5d) and (6d). The second form of (6d) says that a charge Q moving at speed v is equivalent to a current Qv.

Since V is an E.M.F., it is convenient to reckon Lv in ohms, as was done before; v is 30 ohms, in air, when it has its greatest value (speed of light, 30 earth quadrants per second) and L is a convenient numeric. L = 20 is a common value (copper suspended wires); in this case our "resistance" is 600 ohms. But it is not "ohmic" or "joulic" resistance; the current and E.M.F. are perpendicular. V is the line-integral of the electric force across the dielectric from wire to wire, and C is the line-integral ($\div 4\pi$) of the magnetic force round either wire. The electric and magnetic forces are perpendicular, and so are V and C regarded as vectors. The product VC is the energy current; their ratio is the important quantity Lv.

In a positive wave V and C are similarly signed, and in a negative wave are oppositely signed. Thus, if the electrification be positive, the direction of the current is the direction of motion of the wave; whilst if it be negative, the current is against the motion of the wave.

When oppositely travelling waves meet, the resultant V is the sum of the two V's, and the resultant C the sum of the two C's.

Thus, if the waves be so shaped as to fit, then, on coincidence, V is doubled and C is annulled. The energy is then all electric. But if the electrifications be opposite, V is annulled and C is doubled, on coincidence. The energy is then all magnetic. On emergence, however, the two waves are unaltered, save in the attenuation that is always going on.

The electric energy is $\frac{1}{2}SV^2$ per unit length of circuit, and the magnetic energy is $\frac{1}{2}LC^2$. From this, by (6d) and the second of (2d) we see that the electric and magnetic energies are equal in a solitary wave, either positive or negative. The dissipativity in the wires is RC^2 and outside them KV^2 per unit length of circuit. These are also equal, for the same reason.

Should the disturbance be given arbitrary, *i.e.*, V and C any function of x, the division into the positive wave V_1 and the negative wave V_2 is effected thus :—

$$V_1=\tfrac{1}{2}(V+LvC), \qquad V_2=\tfrac{1}{2}(V-LvC). \quad . \quad (7d)$$

Notice that $SV_1V_2=-LC_1C_2$, so that the total energy per unit length is always

$$S(V_1^2+V_2^2)=L(C_1^2+C_2^2). \quad . \quad . \quad . \quad (8d)$$

Similarly, the total dissipativity is always

$$R(C_1^2+C_2^2)=K(V_1^2+V_2^2) \quad . \quad . \quad . \quad (9d)$$

Similarly, the total energy current is always

$$V_1C_1+V_2C_2, \quad . \quad . \quad . \quad . \quad . \quad (10d)$$

since $V_1C_2=-V_2C_1$.

If at a given moment $V=V_0$ through unit distance anywhere, with no C, this immediately breaks into two equally big waves, one positive, the other negative, which at once separate. If initially there be no V, but only C, the same is true for the

current waves; *i.e.*, the result is two equal but oppositely signed V waves, which at once separate.

What happens when disturbances reach the end of the circuit depends upon the nature of the terminal connections there. At present only one case—the simplest—will be noticed. Let there be a resistance of amount Lv at the distant end B of the circuit. The terminal condition is then $V = LvC$. But this is the property of a positive wave. Hence all waves travelling towards B are immediately *absorbed* on reaching B. The electricity is all gobbled up at once, so to speak. Similarly, if there be a resistance Lv at the end A (where $x = 0$) it imposes the condition $V = -LvC$, which is the property of a negative wave, so that all disturbances on arrival at A are absorbed immediately. Thus, given the circuit in any state of electrification and current, without impressed force, it is wholly cleared in the time l/v at the most, l being the length of the circuit.

Now, let the circuit be short-circuited at A, and have a resistance Lv at B. Insert an impressed force e at A momentarily, producing $V = e$ through unit distance, say. This will travel towards B at speed v, attenuating as it goes, and on arrival at B what is left will be at once absorbed. This being true for every momentary impressed force, we see that if it be put on at time $t = 0$, and kept steadily on thereafter, the full solution is

$$V = e.\epsilon^{Rx/Lv} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11d)$$

from $x = 0$ to $x = vt$, and zero beyond. Thus the steady state at a given point is instantly assumed the moment the wave front reaches it. After that, there is still transfer of energy going on there, viz., to supply the waste in the part of the wave that has passed the spot under consideration, and to increase the energy at the front of the wave. The current is V/Lv, as before. On reaching B, the current is

$$C = \frac{e}{Lv}\epsilon^{-Rl/Lv} = \frac{e}{Rl} \times \frac{Rl}{Lv}\epsilon^{-Rl/Lv} \quad . \quad . \quad . \quad (12d)$$

If we let Rl the resistance of the circuit be 3,000 ohms, which is 5 times the before assumed value of Lv, then the received current is

$$C = \frac{e}{150Lv} = \frac{e}{90{,}000} = \frac{e}{30Rl} \quad . \quad . \quad (13d)$$

The attenuation is such that the current is one-thirtieth part of the full steady current with perfect insulation.

The electrostatic time-constant of the circuit is

$$RSl^2 = \frac{l}{v} \times \frac{Rl}{Lv} \quad . \quad . \quad . \quad . \quad (14d)$$

or, in our example, five times the time of a journey from A to B. It may have any value we please. If we want it to be ·1 second, l/v must be ·02 second, and therefore $l = 6{,}000$ kilometres, which requires $R = ·5$ ohm per kilom. This is lower than that of any telephone line yet erected. But to make the electrostatic time-constant ·05 second, with the same attenuation, it must be 3,000 kilom. at 1 ohm per kilom.

If e vary in any manner at A, the current at B is given by (12d), in which e varies in the same way at a time l/v later. As there is no distortion it becomes a question of suitable instruments. With proper instruments no doubt the permissible attenuation could be much greater, and the circuit much longer. Again, if we raise the insulation we lessen the attenuation. We bring on distortion, but a good deal is allowable, so that again we can work further. The insulation resistance should be ·36 megohm per kilom. in the 3,000 kilom. example; the product of the resistance of any portion of the circuit (wires) into the insulation resistance of the corresponding part is $(Lv)^2$. In the 6,000 kilom. example it should be ·72 megohm per kilom. But if it be not arbitrary waves, but only waves of high frequency that are in question then we may approximate to the nondistortional transmission without attending to the exactly required leakage.

(To be continued.)

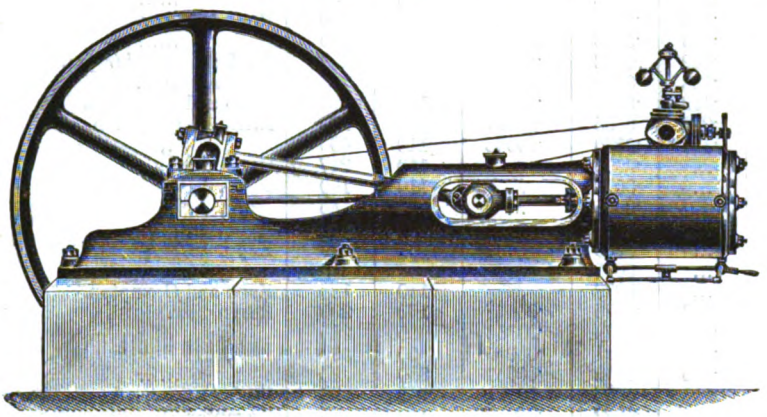
QUICK-SPEED STEAM ENGINE BY RANSOMES, SIMS, AND JEFFERIES.

The accompanying figure represents a new design of Messrs. Ransomes, Sims and Jefferies for a quick-speed engine specially suited for electric lighting work. The makers supply the following details of the design :—In this engine the bed plate, cross head guides and plummer blocks for crank-shaft are all cast in one piece, the cylinder, with its valve chest, being bolted to the end of the engine frame. This design is very strong, neat and compact. The foundation plate is planed on the underneath side for facility of fixing. The fly-wheel is of ample width for giving off the full power



Ransomes, Sims, and Jefferies' Quick-Speed Engine.

of the engine. A force pump, with brass valves and seatings, worked by an excentric from crankshaft, is supplied when desired.

THE NEWTON PRIMARY BATTERY.

The advantages of electric lighting by means of the primary battery are so numerous and so obvious that it is scarcely to be wondered at if, in spite of the long record of past failures, determined and persevering attempts are still being made to overcome the difficulties which have hitherto proved an insuperable barrier to any extensive employment of the method. It is a little unfortunate that these difficulties are chiefly of a character which do not impress themselves forcibly upon the inexperienced and non-technical mind. Results of an apparently economical and satisfactory kind are very readily obtained with many different cells so long as the scale of working is confined within narrow limits ; but the margin of commercial profit only too often diminishes to the vanishing point as soon as the problem is fairly faced upon an extended scale of working.

If we are somewhat unhopeful in the tone of these remarks, it is not because we think that the Newton cell stands any worse chance of success than certain others which we could name, whose failure has resulted as much, or more, from lack of business capacity in the management as from any inherent defects in the system. We take it that a primary battery which is capable of doing service at a fairly economical rate, and also (this is of the first importance) without entailing annoyance or inconvenience upon the user, has a distinct field open to it, in which an extensive business might in time be done, notwithstanding the fact that the cost of electric lighting by this means does not admit of comparison on equal terms with gas. On this point we have often stated our firm conviction, which we have never yet found occasion to alter, and which is shared by all who are really qualified to form an opinion, that a battery consuming zinc as fuel is not able, and until the cost of zinc is vastly lower never will be able, to compete with gas on anything like equal terms.

But, while maintaining this opinion unchanged, we have to recognise the existence of a type of cell—Mr. Newton's among the number—for which the claim is made that, although zinc is consumed in the cell, yet it is recovered in a saleable form—as oxide or as sulphide. The formation of bye-products, which shall cover or materially reduce the cost of working a battery has always, and naturally, had a fascination for electro-chemists, and numberless efforts have been made to solve the problem in a commercial sense. If these efforts have hitherto been without success, it does not by any means follow, nor should we be disposed to predict, that all future attempts of a similar character will remain equally barren of result.

We have already hinted that in the Newton cell the zinc is recovered in a saleable form, but we are unable to express an opinion as to the value of the process, inasmuch as the patents not having been completed at the time of our inspection of the cell, it was reasonably preferred not to disclose the secret. Our readers will, however, easily be able to understand the general drift of the method of the working which is to be adopted, if we state that the Newton is a single-fluid cell, and, like the Lalande, consists of a plate of zinc in a solution of caustic potash ; the negative plate, which may be either iron or copper, being surrounded by a layer of peroxide of lead packed in a parchment bag of narrow width. The peroxide acts, of course, as a depolariser ; oxide of zinc is formed and is dissolved in the caustic potash. The purely electrical properties of the cell were reported on some time ago by Dr. Walmlsey. The following is an extract from his report :—

"Three of the above cells were joined up in series and discharged through a small resistance with the intention of testing them under a current of rather more than three amperes. The E.M.F. on open circuit immediately after pouring in the liquid was 0·75 volt per cell ; but some preliminary tests extending over a few hours having been made in order to gain some idea of the possible behaviour of the cells, the E.M.F. on starting the above-named current was only 0·69 volt per cell. An abstract of the results is given in Table A.

"During the whole of these experiments the external resistance was not altered. The rise of the current during the earlier part of the test is due to the decrease in the internal resistance, and its more rapid fall in comparison with the fall of E.M.F. was due to an increase of internal resistance. These phenomena were observed in the previous cells. The actual internal resistance was 0·87 ohm per cell at starting in the preliminary tests, 0·133 ohm at the 103rd hour, and much higher when the circuit was broken. The above results speak for themselves.

"The fourth cell was tested for the effect of local action. It was short-circuited through a few inches of No. 18 copper wire for 9½ hours. The zinc plate was then carefully weighed and replaced in the cell. At the end of eight days it was again weighed, and was found to have lost only 3·80 grammes, showing that the local action is practically negligible. No tests were made of the composition or probable value of the bye-products or of other points that are important from a commercial point of view for lighting purposes, my instructions being to report only on the electrical behaviour. My tests show that currents of the order required for the above purposes may be taken from the cells for many successive hours."

TABLE A.

Time in hours from commencement of experiment.	Current in amperes.	Average electromotive force per cell in volts.
0	3·45	0·69
11	3·45	—
33	3·57	0 69
50	3·45	—
60	3·30	—
84	3·30	0·68
111	3·17	—
122·5	3·13	0·63
130	2·98	0·61
155	2·27	—
165	1·99	0·59

From this report it will appear that although the E.M.F. is very low, yet the cell possesses undoubted merit. While, however, we have pleasure in recognising this, and are anxious that the battery should have fair play, we feel it all the more strongly to be our duty to appeal to the syndicate in its own interests to take warning by the fate of similar ventures, some of them quite as promising at first sight, which have been wrecked by injudicious (we might use a much stronger term) and extravagant predictions.

Our appeal is not by any means superfluous in this case, as a glance at the printed statements made by the New Electric Light Syndicate will show. The first line reads "Electricity as cheap as gas," and, to make only one other quotation, we read "A brilliant and steady light is maintained for 120 hours without attention. Most other batteries last only a few hours." This kind of thing is certainly a tactical mistake, and we take it to be the truest kindness to say so. The appearance of the Newton cell is *not* an era-marking event, even though it should prove, as we hope it may, a serviceable type of battery.

THE MEASUREMENT OF SELF-INDUCTION, MUTUAL INDUCTION, AND CAPACITY.*

BY W. E SUMPNER, B.SC.

It has long been known in a general way that the effects of self-induction and capacity are opposite in kind. Self-induction in a relay produces sparking, but if a condenser be shunted to the relay sparking is prevented. Condensers are used in induction coils to prevent sparking and to hasten change of magnetisation. Mr. Preece told us while discussing Prof. Hughes's paper that a resistance shunted by a condenser is placed in a telegraph circuit to overcome the effects of self-induction. Prof. Silvanus Thompson told us (*Journal*, May 13th, 1886) that Mr. Black, in 1878, "showed that one difficulty in long-distance telephoning could be effectually got over by putting a condenser in the circuit as a bridge to any electro-magnet in the line." The reason of this is possibly that the condenser diminishes the effective self-induction of the line. Mr. Blakesley remarked on the same occasion that the working of a telephone circuit completed through a condenser could be improved by adding self-induction to the circuit up to a certain amount. After that maximum had been reached, an increase of the self-induction of the circuit or a diminution of its capacity would be a disadvantage. Now possibly the reason of this is to be found in the fact that capacity is like a negative self-induction. Capacity in a circuit helps change of current. Self-induction in a circuit hinders change of current. Just as self-induction in a telephone circuit retards some of the waves of current more than others, and thereby renders impure the sounds given out, so capacity in a telephone circuit accelerates some of the waves more than others, and produces a similar result. The ideal telephone circuit should have no effective self-induction. What the resistance of it is does not matter so much. When Mr. Blakesley added self-induction to his telephone circuit, the improvement he noticed in the working was probably not because the mere addition of self-induction was an improvement, but because the effect of the capacity was diminished more and more as self-induction was added, until a point was reached when the effect of the latter counterbalanced that of the former. It was then that the line worked at its best. It was then that the waves of current travelled along the line without changing much in form.

In working with the secohmmeter it is possible to make the resistance of the coil having self-induction appear either to increase or to decrease, according to the way in which the commutator is turned. It is even possible by turning the secohmmeter at a particular speed to reduce the apparent resistance of the coil to zero. The reason is that self-induction when currents are increasing acts like an increase of resistance, and when currents are diminishing like a diminution of resistance. Exactly the reverse holds good of capacity. In the armature of a dynamo self-induction acts like an increase of resistance because the current has to be started in each coil as it passes the commutator. If it were practicable to shunt each coil of the armature by a condenser, the effect of capacity would be that of a diminution of resistance each time the coil passed the commutator. Just as the resistance of an armature is effectively increased by its self-induction, and increased by an amount proportional to its speed, so the result of capacity would be to diminish the effective resistance by an amount proportional to the speed. If, therefore, it were practicable to use condensers of suitable capacity, it would be possible not only to get rid of the effect of self-induction, but actually for a particular speed to diminish the effective resistance of the armature to zero.

It is important to consider whether the opposite natures of self-induction and capacity can be utilised practically in diminishing the self-induction of transformer circuits.

In the appendix of the paper of Profs. Ayrton and Perry will be found two or three methods which I devised for measuring self induction. In each of those methods a condenser, shunted to the coil, was used to prevent sparking at the intervals between the reversals; and although the condenser was afterwards dispensed with because a short circuit was allowed to occur, yet the formula was first worked out in each case on the supposition that the condenser was used. The result came out in every instance just as if the condenser had been absent, and as if the self-induction of the coil had been diminished by the product of the capacity of the condenser and the square of the resistance of the coil shunted to the condenser.

Now, this not only showed that each of the methods for measuring self-induction was also a method for measuring capacity, but it seemed to indicate that there was some law regulating the external action of a condenser shunted by a wire.

The law was easily found to be as follows:—In any network of conductors, if one of the branches be composed of a condenser whose terminals are shunted by a wire, with or without self-induction, and if the currents in the network vary from any cause from one steady set of values to another, the extra quantity of electricity which will pass through a galvanometer placed in any arm of the network, in consequence of the capacity, will be exactly as if the condenser were altogether removed and the self-induction of the wire were diminished by the product of the capacity of the condenser and the square of the resistance of the wire shunting it.

Let E be the electromotive force, constant or variable, applied to the terminals of a condenser through a resistance R; let K be the capacity of the condenser, r the resistance, and L the coefficient of self-induction of the wire shunting the condenser; let x be the current through the wire r, and y the current through the condenser, and let V be the potential difference of the condenser terminals at any moment; then

$$E - V = R\,(x+y),\quad V = r\,x + L\frac{dx}{dt},\quad y = K\frac{dV}{dt};$$

whence $$E = (R+r)(x+y) + (L - K r^2)\frac{dx}{dt} - K L r \frac{d^2x}{dt^2}.$$

The extra current due to K and L will be that caused by the extra electromotive force

$$(L - K r^2)\frac{dx}{dt} - K L r \frac{d^2x}{dt^2},$$

and the total quantity of electricity passing through a galvanometer placed in any other branch of the network will be proportional to the integral of this extra electromotive force. If the currents in the network vary from one steady state to another, the integral is

$$(L - K r^2)(x_1 - x_2),$$

where x_1 and x_2 are the two steady currents through the wire. Now, as these are not affected by K, the effect on the galvanometer is exactly as if the condenser were removed and the self-induction of the wire were diminished to

$$L - K r^2.$$

The effect of the capacity is that of a negative self-induction. It may be said to be due to this cause that it is possible to compare self-induction with capacity in the way described by Clerk-Maxwell.

It seems very strange that Clerk-Maxwell, who devised a method for measuring self-induction absolutely, and who also gave methods for comparing self-induction, mutual induction, and capacity, failed to observe that his absolute method was equally applicable to the measurement of all these quantities. If a galvanometer be placed in one of the branches of any network of conductors, such as the Wheatstone bridge, the effect on the galvanometer due to different electromotive forces acting in different branches of the network is well known to be the sum of the effects produced by each electromotive force acting separately. Now the effect of self-induction in a wire through which a varying current is passing is to generate an electromotive force in the wire proportional to the rate at which the current varies. Mutual induction and capacity produce similar effects. So that, while currents are being established in a Wheatstone bridge in and between the branches of which exist induction and capacity, the extra current through the galvanometer will be that caused by the extra electromotive forces in the network, and will be the sum of the extra currents produced by each of these electromotive forces taken separately. The total quantity of electricity going through the galvanometer in consequence of the induction and capacity will be a simple linear function of the coefficients of those quantities.

Indeed, Maxwell has shown that if self-induction exists in one of the arms of a Wheatstone bridge which is balanced for steady currents, the fling of the galvanometer when the galvanometer circuit is closed before the battery circuit, is directly proportional to the self-induction. He has, moreover, shown that it is possible to balance the bridge for both steady and variable currents, provided a certain relation holds between the resistances of the arms and the coefficients of induction or capacity that are being compared. If, for example, as in Fig 5, we are comparing self-induction with the capacity, suppose L is the self-induction of the branch r, and K is the capacity shunted to the branch q, then if $p\,s = q\,r$ and $K\,q\,r = L$, Clerk Maxwell has shown that the bridge will be balanced for both steady and variable currents. Now this shows that the effect of K is equal and opposite to that of L; and since the swing of the galvanometer when K is removed is proportional to L, it follows that the swing of the galvanometer when L is removed is proportional to K. The same remark applies to mutual induction. It at once follows that Clerk-Maxwell's method of determining self-induction in absolute measure is also a method of determining mutual induction and capacity in absolute measure. We have merely to proceed in exactly the same way as when determining self-induction, and to divide the result we obtain by a simple ratio or a simple product of the resistances in the arms of the bridge.

Perhaps Clerk-Maxwell missed seeing this because he foresaw the existence of null methods and did not consider the meaning of the galvanometer swing when the bridge, although balanced for steady currents, was not balanced for variable currents. However this may have been, the null methods of Clerk-Maxwell form an example of how very tedious and difficult to work null methods may sometimes become. It is not only necessary to have a very delicate galvanometer and an extremely delicate adjustment of the bridge, but only one particular adjustment of the bridge will give any result at all, and for this reason these double null methods are quite unsuited to those to whom time is any object.

Once, however, the fact is grasped that the swing of the galvanometer in a bridge balanced for steady currents is a linear function of the inductions and capacities in the bridge, it is easy to see a much more rapid way of comparing the coefficients than by the methods of Clerk-Maxwell.

Let L_x be the self-induction of the branch x; let K_x be the capacity of the condenser shunted to the branch x; let M_{xy} be the mutual induction of the branches x and y.

If we are comparing L with M, as in Fig. 6, we have

$$L_s + \frac{p+r}{p} M_{sb} = k D_1,$$

where p and r are the resistances of the branches as indicated in the figure, D_1 is the first swing of the galvanometer when the bridge being balanced for steady currents has an electromotive force suddenly put in the battery circuit, and where k is some constant.

Now reverse the connections of either of the coils possessing mutual induction. The bridge is not altered except that the sign of M_{sb} is

* Paper read before the Society of Telegraph-Engineers and Electricians, on May 12th.

Digitized by Google

charged. If we now take another swing, we get

$$L_s - \frac{p+r}{p} M_{sb} = k D_2 ;$$

whence

$$L_s : M_{sb} = \frac{p+r}{p} \frac{D_1 + D_2}{D_1 - D_2}.$$

If we are comparing two self-inductions, as in Fig. 1, we get in the same way, after balancing the bridge,

$$p L_s - r L_q = k D_1.$$

Now remove the branch q and substitute resistances till the bridge is again balanced. We then have

$$p L_s = k D_2 ;$$

whence

$$\frac{L_s}{L_q} = \frac{r}{p} \frac{D_2}{D_2 - D_1}.$$

If we are comparing two capacities, as in Fig. 3, which represents a generalised form of De Sauty's method, we have in the same way (if the bridge is balanced for steady currents)

$$s K_s - q K_q = k D_1 ;$$

by removing the connections of the condenser q we have

$$s K_s = k D_2,$$

or

$$\frac{K_q}{K_s} = \frac{s}{q} \frac{D_2 - D_1}{D_2} = \frac{r}{p} \frac{D_2 - D_1}{D_2}.$$

This must hold when the resistances s and q are infinite—*i.e.*, in De Sauty's method. In this case, however, as well as in the case represented in Fig. 2, the swing method is needless, as a single null method is applicable.

If we are comparing capacity with mutual induction, as in Fig. 4, we get in the same way

$$\frac{q+s}{q} M_{rb} - q r K_q = k D_1 ;$$

and by disconnecting the condenser we get

$$\frac{q+s}{q} M_{rb} = k D_2,$$

or

$$M_{rb} : K_q = \frac{q^2 r}{q+s} \frac{D_2}{D_2 - D_1}.$$

If we are comparing self-induction and capacity, as in Fig. 5, we get

$$L_r - q r K_q = k D_1 ;$$

and by removing the condenser,

$$L_r = k D_2,$$

$$L_r = \frac{D_2}{D_2 - D_1} q r K_q .$$

q r must generally be large, and it is better to make q larger than r.

The following table gives the results of a set of experiments made on an induction coil the ratio between whose coefficients of self and mutual induction was required. The ratio $r : p$ of the arms of the bridge was varied from 50 to 200, the ratio of the coefficients being about midway between these numbers.

MUTUAL INDUCTION AND SELF-INDUCTION.

Ratio of arms r/p.	Induction measurement.	Mean swing.	Sum of swings.	Ratio, L·M.	Error from mean.
57·10	L+58·1M	565	774	126·3	0·9
	L−58·1M	209			
71·77	L+72·8M	601	765	127·4	0·2
	L−72·8M	164			
82·15	L+83·1M	595	720	127·4	0·2
	L−83·1M	125			
100·77	L+101·8M	594	659	126·8	0·4
	L−101·8M	·65			
127·07	L+128·1M	545	542	126·7	0·5
	L−128·1M	−3			
206·99	L+208M	531	406	128·5	1·3
	L−208M	−125			
			Mean = 127·2		0·6

On looking at the column headed "Sum of Swings," we see that the numbers gradually diminish to the null position. Now, these numbers in each case correspond with the constant amount of induction 2 L, and must therefore be a measure of the sensibility of the arrangement of the bridge. The striking fact comes out that in this particular case the double null arrangement was that of least sensibility. The reason of this is not far to seek. In measuring resistance by the Wheatstone bridge the sensibility, for the same galvanometer and battery, depends upon the way in which the bridge is arranged. Now the effect of induction or capacity for variable currents is exactly comparable with that of a variable resistance, so that the bridge, although balanced for steady currents, may be regarded as deranged for variable currents, and the effect on the galvanometer will be greatest when the bridge is joined up for the measurement of resistance in the most sensitive way. It by no means follows that the most sensitive arrangement of the bridge will be the particular arrangement necessary for the null position.

It therefore becomes questionable whether the double null arrangement is worth the trouble of getting. Those who invariably perfer null methods make an assumption which is not true. They assume no less than the possession of a galvanometer of infinite sensibility. All they really have is one galvanometer which is the most sensitive at their disposal, and the best arrangement they can have is that which will, with that particular galvanometer, yield the most sensitive results. However, those who have an extremely sensitive galvanometer or an extremely unreliable battery can use this method of swings merely as an approximation to indicate the null position, and may thereby save much time.

There is a more important consequence of the fact that the extra current through the galvanometer is a linear function of the coefficients of induction and capacity. All Maxwell's comparative methods may be turned into absolute methods, and either Maxwell's absolute method, or, still better, the absolute method of Profs. Ayrton and Perry, can be applied to each one of them. Figs. 1 to 12 illustrate this.

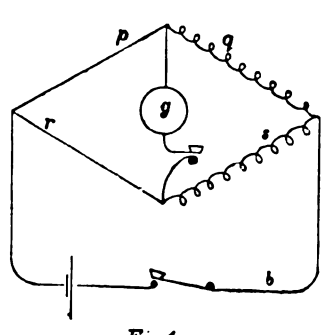

Fig. 1.

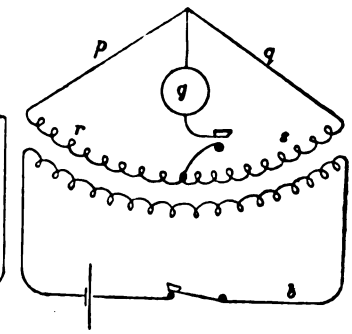

Fig. 2

Fig. 1 represents Maxwell's method of comparing two self-inductions, but we may regard the self-induction in the branch q as removed, provided we suppose that of the branch s to be

$$L_s - \frac{r}{p} L_q.$$

Fig. 2 represents Maxwell's method of comparing two mutual inductions. Fig. 11 represents the same method when the current runs through the bridge. For mere comparison it is better to use the arrangement of Fig. 2. For absolute measurement it is better to use the arrangement of Fig. 11. In the latter case we may regard the effective self-induction of the branch p as being

$$\frac{s+q}{s} M_{pb} \pm \frac{r+p}{s} M_{qb},$$

and we may regard the mutual induction as being altogether removed.

(To be continued.)

STORAGE BATTERIES IN PRACTICE.*

BY EDWARD P. ROBERTS.

Since I had the honour of reading a paper on storage batteries at the annual meeting of 1885, we have discarded storage batteries distributed in various localities as the source of supply of current to our incandescent lamps, and have now all lamps connected with our incandescent dynamos. Having, however, a large number of cells we have placed in position at our station about 1,200 of the same, charging them at night and using the stored current for day lighting and power, both of which are small in amount. In case of an accident to our machinery at night we could use our storage plant to tide over the time required for repairs, or until the majority of lights could be turned off. We have not yet had call, however, for such service, although we always have the batteries charged to a considerable extent before dark.

Since 1885 we have tried crockery and glass cells, with plates *suspended* in the same from glass rods and separated by glass rods from each other. This was a great improvement. The cells are placed on beams of a triangular cross-section, having a four-inch base, which, in turn, rest on glass insulators, Western Union pattern, screwed on pins fastened on cross pieces. The beams are first painted and then given a coat of paraffin. The insulation from cell to cell is much improved thereby. When lead cells are used they are placed on porcelain insulators on the beams; flat places being cut on the vertical angle of the beam.

I am informed, with what degree of correctness I do not know, that storage batteries have been much improved lately, over those with which I have had experience, but, even if such should be the case, I should hesitate to use them where gas lighting is cheap and where it might be desired to use only a *few lights* in *each* of a *large* number of localities separated by considerable distances. For special cases, however, I have no doubt the storage batteries can be used advantageously, particularly when the advantages of incandescent electric lighting are considered as being of financial value.

A few of the disadvantages arising from the conditions in the first part of the above paragraph are:—

1st. A large plant in each locality is needed because of possible drain on same. The ordinary use in a residence may be 15 lamp hours and the possible use 100 lamp hours. This is an extreme example, but is not exaggerated, as it was the necessary margin we had to provide when we had storage plants in each house requiring light for from 15 to 20 per cent. of our customers. If several customers can be supplied from one battery plant the margin of extra supply can be reduced. In such case

* Paper read at the meeting of the American Institute of Electrical Engineers, May 18th, 1887.

Digitized by Google

it will be necessary *either* to connect all the customers on all the batteries connected in multiple arc, and then disconnect the batteries and charge same in series, or, if it is desired to use a meter system in which discharge bears a certain proportion to charge, an attendant must be ready to throw extra batteries on circuit needing same, and note name of customer using extra supply.

2nd. A large number of plants means a number of small stations to maintain and at which to keep supplies—distilled water, acid, &c.

3rd. With a number of small stations it is difficult to regulate E.M.F. to current desired. However small the percentage of E.M.F. lost in the discharging wires the E.M.F. of the batteries should rise as lamps are turned on, or the lamps will be below candle-power, when a number are used, if for one or two the proper E.M.F. is used ; or it will be necessary to strain the lamps when a few are used, in order to have normal brilliancy when a number are desired. To still further complicate matters, the E.M.F. is higher at the start, particularly if only a few lamps are "on," than it is later in the evening. These differences in E.M.F. are small, but are sufficient to vary the candle-power of the lamps.

If, therefore, each customer is connected with one or more batteries for his sole use the following takes place :—As darkness approaches one or two lights are turned on and are raised to abnormal candle-power straining lamps and making consumers di satisfied with any less light later on, and as the customer's eyes become tired the light drops, possibly not below the normal candle-power, but the *comparison* is bad, and it requires considerable power of persuasion on the part of the company's "talker" and loss of his time as a "worker" to make the customer believe that his eyes are at fault and not the light. It may be that an entertainment is given in the house, and then the drop of candle-power is more noticeable, although it may not fall much below the normal.

Of course it is possible to design mechanism to overcome all such troubles, to throw in extra cells and extra batteries as required, &c. To design mechanism to accomplish such work with reliability, and which will not be too costly for maintenance or prohibitory on account of excessive first cost, is undoubtedly a problem. Matters are further complicated by the necessary use of charging mechanism. Also, it is desirable to have switches so arranged that it will be impossible to have charging current "on" when lights are being used *from* a battery. The writer has run 1,000 lights in such a manner (with charge on) for over a year, but does not advise it from any standpoint except necessity.

If a few large stations are used the E.M.F. at same can be readily shown at main station, and regulated from same if desired, or an attendant can be sent to any station needing regulation.

My experience teaches me that if batteries can be charged under inspection and allowed to have a discharge without excessive variation in amount of same, that the batteries will give *much more reliable* results than in any other way. The nearer this can be approached the more satisfactory will be the service.

If, therefore, it seems to be advisable in any city to erect a storage battery system for general distribution, I believe it will be found best to erect a very few large battery stations at the various centres, and that the interest on the extra cost of the wire leading from the same to the lamps, over what would be necessary if each light were close to a battery, will be far more than saved in the lessening of attendance alone, and that the avoidance of other evils I have mentioned will thus be clear gain.

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subject. connected with Electrolysis :—

ON THE MIGRATION OF IONS AND AN EXPERIMENTAL DETERMINATION OF ABSOLUTE IONIC VELOCITY.

BY DR. OLIVER LODGE.

(Concluded from page 104.)

Experiment on the travelling of hydrogen.

August 17.—The same apparatus as in Fig. 10 was again used, but the solutions arranged as follows :—In cathode vessel, sat. solution of $CuSO_4$ as before ; in anode vessel, dilute sulphuric acid ; in tube, the following : 49 cc. of sodic chloride sol. (5 grammes salt in 100 water) with 1 cc. of baric chloride sol. ($BaCl_2$, 2Ag centigrammes, or 2·44 of the crystallised salt, in 100 cc. water) ; add to this a little phenol-phthallein, and just enough NaHO to make it red. The destroying of the colour is the thing observed. No measurements made till the liquid is discoloured round the bends of the tube. At xvii. 43 the current was started, with an E.M.F. of 45 volts between terminals. The galvanometer deflection increased from 41·1° to 44·2° in the first half hour, and then increased further to 46° in the next hour. By xvii. 51 the decolorisation had got round the bends, and the first or starting mark was made. The progress of the whole experiment was rapid.

In the preceding summary the column headed 'Progress of SO_4' gives the position of the marks made near cathode end of the tube. The column headed 'Progress of H' gives the position of the marks made near the anode end. By these headings it is not intended to insist that the full theoretical meaning of the observations is the same as the obvious and apparent meaning. All distances are specified in centimetres.

The progress of the experiment is represented pictorially in Fig. 13.

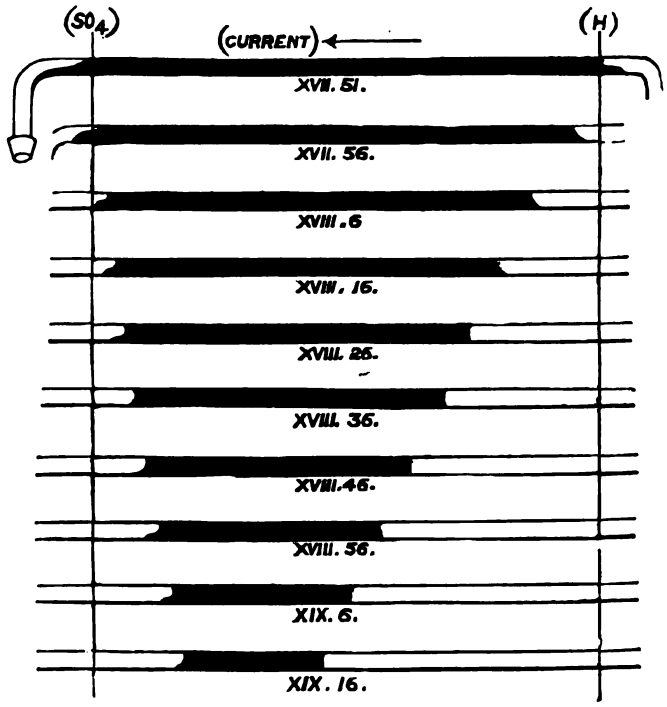

FIG. 13.

August 18.—Another similar experiment, but with a little more NaHO added to liquid in tube to make colour more distinct. No good observation could be obtained of the SO_4 progress this time, as it did not get up to the bend, but the H progress was read. The tube was graduated in millimetres for this experiment. 45 volts applied.

	Boundary getting indistinct.	

* It would seem probable that there was some unknown misreading here; probably 7 for 9.

The double number in the middle column represents the two ends of a slope into which the boundary threw itself as soon as the current was stopped; indicating convection. A galvanometer deflection of 45° means a current of ·009 ampere.

In the last experiment the tube was not perfectly horizontal, and this may have caused some disturbance. In future experiments the tube was carefully levelled to begin with.

Experiment on velocity of copper.

August 24.—Started an experiment with $CuSO_4$ in both vessels, and in tube some NaCl with a little K_4FeCy_6. But the indicator did not form a sharp boundary across the tube, and the experiment was not very satisfactory. 65 volts applied.

		Current in milliamperes.

Experiment on the velocity of hydroxyl.

August 25.—Made an experiment on the rate of travel of the hydroxl radicle of NaHO, by using the closed $CuSO_4$ vessel with copper electrode as *anode* vessels and putting a solution of soda in the open (now) cathode vessel. The tube contained NaCl (5 grammes in 100 cc.) with a little phenol-phthallein not coloured as yet with alkali. The appearance of colour was the thing to be observed as the HO travelled against the current and attacked the NaCl. 65 volts applied to electrodes. Tube 40·7 cm. long. For diagram of results see Fig. 16.

Experiment on the velocity of ammonium.

August 26.—Made several attempts to get the speed of NH_4 using Nessler solution. The indicator is not very distinct: no precipitates seem to work well as indicators; they introduce disturbances. Fluid detectors answer better.

Ammonic sulphate was put in anode open vessel.

The tube contained NaCl + Nessler solution. 65 volts supplied.

Current stopped because boundary was getting indistinct. This did not seem a very good experiment, but it is better than some here unrecorded which preceded it.

August 26.—A similar experiment with a drop of phenol-phthallien added to liquid in tube, because its indication is sharper. Boundary, however, still sloping, and therefore unsatisfactory to read.

Further experiments on the meeting of Ba *and* SO_4 *in jelly tubes.*

It may be remembered that, whereas in free liquid, Ba appeared to travel about three times as fast as SO_4, the precipitated plug of $BaSO_4$ nearly always appearing much nearer the Na_2SO_4 or cathode end of the tube than near the $BaCl_2$ end, yet in jelly tubes they appeared to travel at about the same rate, the plug of precipitate forming near the middle of the tube. To make sure that there was no error of observation here, and to see if constitution of jelly affected the matter, a few experiments with jelly tubes were repeated, and different strengths of jelly were used.

August 24.—Two tubes, each 40 centimetres long, were filled with jelly made by dissolving 40 grammes of gelatine in 150 cc. of dilute acetic acid, of strength one centigramme molecule in 5 cc.

Another pair of similar tubes were filled with jelly made with 40 grammes of gelatine dissolved in 150 cc. of four times weaker acetic acid, viz , a centigramme molecule in 20 cc.

58 volts were applied to the carbon electrodes of all four tubes. The anode and cathode vessels contained $BaCl_2$ and $CuSO_4$ respectively.

In the tubes with weak acid, $BaSO_4$ began to form in 28½ hours after starting the current, and its position was 19·3 in one tube, and 19·2 in the other, from the $BaCl_2$ end, and therefore 19·7 and 19·8 from the Na_2SO_4 end.

In the tubes with stronger acid the precipitate took some hours longer to form, and its position was 19·2 in one tube, and 18·3 in the other, from the barium end. The relative speed of travel of Ba in the two pairs of tubes was taken by making simultaneous marks on each tube as the Ba proceeded ; and the ratio of these rates was in the weak acid tubes 1 21 times that in the stronger acid tube.

Thus, although the absolute speed is less in the stronger acetic acid jelly (as is quite right, because its conductivity is less ; see above), the ratio of speeds of Ba and SO_4 remains practically unity in both.

August 27.—To confirm, the four tubes were started again in just the same way, except that, while one pair contained jelly with $C_2H_3O_2$ centigramma molecules in 5 cc. as before, the other pair contained jelly with $C_2H_3O_2$ centigramme molecules in 40 cc. The distance travelled by Ba in the weak acid jelly tubes was 15·3 cm., and in the strong acid jelly tubes was 12 4 in the same time ; giving a ratio 1·20 as before.

So far as it is wise to draw a moral from unfinished experiments it may be said that, while there are some divergencies, yet they are in the main confirmatory of the theory of Professor F. Kohlrausch, especially in the case of the velocity of hydrogen ; and I think it may be regarded as a noteworthy instance of scientific prediction if numbers calculated theoretically from conductivity data be found to agree at all closely with the results of direct experiment.

In conclusion I wish to record my best thanks to my assistant, Mr. Edward Robinson, for the care and assiduity he has bestowed upon these experiments. As I have had occasion to remark in the course of the paper, he has not only carried out my proposals with ingenuity and skill, but he has in several cases modified details and devised fresh combinations.

CHEMICAL SOCIETY.

ON A NEW CLASS OF VOLTAIC COMBINATIONS IN WHICH OXIDISABLE METALS ARE REPLACED BY ALTERABLE SOLUTIONS.

The following is an abstract of an interesting paper read at a recent meeting of the above society by Dr. C. R. Alder Wright and Mr. C. Thompson :—

It appeared to the authors probable that just as a liquid capable of parting with oxygen, chlorine, &c., can be used in conjunction with an electrode of unchangeable material at one side of a voltaic cell (as in Grove's nitric acid battery and analogous combinations), or may be replaced by a solid conducting electrode, itself capable of losing oxygen (*e.g.*, a plate of strongly compressed peroxide of lead), so conversely might a conducting plate of oxidisable material (*e.g.*, zinc) at the other side be replaced by an unchangeable electrode in conjunction with a liquid capable of taking up oxygen, chlorine, &c., without producing any fundamental change in the character of the actions taking place in the cell whilst generating a current. The electrode immersed in this oxidisable substance, like the zinc of an ordinary cell, would acquire the lower potential, and the opposed plate the higher potential ; *i.e.*, the wire connected with the latter would be the "positive pole" of the construction in reference to the external circuit.

On trial, it has been found that such is the case, and that in consequence a large variety of novel forms of cell becomes easy of construction. For example, sodium sulphite or potassium ferrocyanide solution opposed to chromic-sulphuric acid solution ; preferably with an intermediate layer of some neutral salt solution, such as sodium sulphate, to prevent the direct action of the two fluids on one another. During the passage of a current, sodium sulphate or potassium ferricyanide is formed in quantity proportionate to the electricity passing, *i.e.*, to the amount of silver thrown down in a silver voltameter included in the circuit ; whilst chromium sulphate is produced at the other side. Various analogous cells are described, in particular one where lead oxide dissolved in caustic soda is opposed to alkaline hypobromite. In this case lead dioxide is produced and separates out in the solid form ; and one where chromium sesquioxide dissolved in caustic soda is opposed to chromium trioxide dissolved in sulphuric acid. Here sodium chromate and chromium sulphate are formed, an E.M.F. about equal to that of a Daniell cell being set up.

In the discussion which followed,

Mr. PAGE said that after listening to Dr. Wright he was able for the first time to understand how electric currents might arise in the animal body.

Dr. ALDER WRIGHT said in reply to Mr. Page that the experiment suggested of opposing venous and arterial blood had not been actually tried by him as yet, but he thought it quite probable that a weak current might be produced. [The PRESIDENT subsequently said that he had been told—he believed by Mr. Peter Squire—that a current was produced on opposing venous and arterial blood.] By opposing alkaline pyrogallol solution to oxidising agents, notable currents could be developed ; and various other organic compounds might be used instead of pyrogallol. With certain organic bodies, however (*e.g.*, chloral hydrate), attempts to produce oxidation in cells had hitherto failed. The opposition of acid and alkaline fluids alone would not necessarily produce more than infinitessimal currents ; Becquerel's "*pile à oxygène*" (nitric acid opposed to caustic potash solution) gave rise to decomposition of nitric acid and evolution of oxygen from the electrode immersed in the alkali ; other authors had found that analogous cells with chromic-sulphuric acid instead of nitric acid would behave in the same way and develop a continuous current capable of doing external electrolytic work such as deposition of silver in a voltmeter ; on the other hand, a cell in which caustic soda and sulphuric acid only were opposed (so that chemical action other than neutralisation could not take place) would only develop an infinitesimal current through a silver voltameter, capable of depositing only traces of silver even after some days, although its E.M.F. measured by an electrometer was considerable.

With regard to the observations of Dr. Armstrong, he would say that whilst without doubt Grove's gas battery was the prototype of the class of cells discussed, inasmuch as that combination was virtually an oxidisable solution of hydrogen opposed to an oxidising solution of free oxygen still the examination of cells in which other oxidisable fluids were used instead of hydrogen solution, and other oxidising substances besides solution of oxygen, was a branch of experiment in which hardly anything had hitherto been done, and which seemed to merit some little attention. The authors desired to study in detail the general behaviour of certain typical classes of cells in which actions of the kind take place, especially from the point of view of elucidating the precise chemical changes going on and their relations to the amounts of electrical (or current) energy developed. Whilst there was not exactly a probability of any very startling discovery being made, there were still a number of points of interest connected with the subject worth examining ; and although the hope of an improved primary battery based on actions of this kind for commercial use, as suggested by the President, was perhaps not yet within measurable distance, yet the problem of economically obtaining current energy by direct chemical action (and especially by oxidation) was one now attracting considerable attention, and it was impossible to predict what might or might not be the result of systematic experiments tending in that direction. The importance of obtaining practically usable currents from coal direct without the use of the steam engine and dynamo could hardly be over-rated should it hereafter be found practicable so to do ; and in view of the compactness of the animal machinery, whereby the oxidation of fuel in the form of food gave rise by muscular action to mechanical energy, it did not seem to be of necessity hopeless to attempt to solve such a problem.

PHYSICAL SOCIETY.—June 11.

Mr. SHELFORD BIDWELL, F.R.S., Vice-President, in the chair.

A number of Puluj and other vacuum tubes were exhibited by Dr. Warren De la Rue. The Puluj tubes consisted of a phosphorescent lamp, and radiometers with phosphorescent vanes and mica discs painted with phosphorescent substances. The other tubes contained different phosphorescent minerals, such as magnesium carbonate, calcium silicate, and Iceland spar. When illumined by a large induction coil beautiful colour effects were produced.

The following papers were then read :—*Note on Beams Fixed at the Ends*, by Profs. AYRTON and PERRY. This paper was not of an electrical character.

Note on Messrs. Vaschy and Torranne's Method of Comparing Mutual Induction with Capacity, by Prof. G. C. FOSTER. In November last the

Digitized by Google

author described a method of comparing the mutual induction of two coils with the capacity of a condenser. Since then he has found that a very similar method was used by Messrs. Vaschy and Torranne in July, 1886, and published in *The Electrician* the following month. The formulæ are identical, and the difference consists in interchanging the galvanometer and the variable resistance *p*. Messrs. Vaschy and Torranne's arrangement has the advantage that the resistance of the secondary coil need not be known. Prof. Foster's method had been used by one of his students (Mr. Draper) about two years ago, but priority in publication belongs to Messrs. Vaschy and Torranne.

Prof. PERRY asked the meeting for suggestions to explain why a strip of steel twisted about its longitudinal axis at a red heat and allowed to cool tends to untwist when under tension? and for a formula to calculate the amount.

A Note on Magnetic Resistance, by Profs. AYRTON and PERRY, was postponed.

COMPANIES' MEETINGS.

The Northern District Telephone Company.

The fifth annual general meeting of the shareholders of the Northern District Telephone Company was held at the offices of the Company, Arcade-chambers, on 13th inst.

After the report of the Directors and statement of accounts had been read and adopted,

The CHAIRMAN (Mr. R. T. Wilkinson) pointed out the very satisfactory progress which the Company had made since the beginning of the present year. In view of the great dulness in trade, and the consequent reluctance on the part of firms to increase their expenditure even by so small an item as an annual telephone rental, he considered the number of subscribers to the company's exchanges to have increased with a rapidity which was extremely satisfactory, the total number at the end of 1886 showing the increase for the 12 months to have been at the rate of no less than 71 per cent. Adverting to the recent increase in the Company's capital from £100,000 to £2.0,000, the Chairman pointed out, as an instance of the confidence shown in the Company, that the whole of the new capital had been taken up immediately it was issued. This he considered to be extremely gratifying. He was also glad to see that a very considerable extension of the system had been carried out, and he had every reason to believe that it would soon make them a very remunerative return. He felt certain that the year 1887 would prove equally as satisfactory to the shareholders, in the matter of increased business, as the last year had, and that notwithstanding the continued depression in trade. The payment of the preference dividends having been confirmed, and the usual vote of thanks to the Chairman passed, the meeting terminated.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 10th June amounted to £4,151.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 10th June were £3,4?4, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE EASTERN TELEGRAPH COMPANY (LIMITED).—According to an advertisement which appears elsewhere, the directors of this company are prepared to issue £4 per Cent. Perpetual Debenture Stock for debentures falling due 1st August, 1887 (bearing interest from 1st May, 1887), in exchange for equal amounts of the company's Five per Cent. Debentures falling due 1st August, 1887, with the coupon due that day attached, and to pay £1 in cash in respect of the said coupon if the debentures are deposited at the company's office on or before 1st of July, 1887. Debentures not so deposited will be paid off at par on 1st of August at the company's bankers, Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, London. The Mortgage Debenture Stock constitutes a first charge on the undertaking and revenues of the company. The amount issuable is by the special resolution creating the same restricted to one-third of the share capital from time to time issued and paid up. The stock is at present quoted on the London Stock Exchange at the price of 101 to 103 per cent.

UNITED TELEPHONE COMPANY'S DIVIDEND.—The directors of this company recommend a dividend for the second half-year ending the 30th April last at the rate of 8s. per fully paid share (part paid shares receiving in proportion), making, with the interim dividend paid on the 26th November last, a total dividend for the twelve months ending 30th April last of 13 per cent. For the second half year ended 30th April, 1886, the dividend was 9s. per share, making a total distribution for the year of 13 per cent.

NOTICES OF REMOVAL.—Notice is hereby given that on and after Monday, the 20th inst, the offices of the Brazilian Submarine Telegraph Company and those of the African Direct Telegraph Company will be removed to Winchester House, 50, Old Broad-street, E.C.

PERSONAL.—Mr. W. Brooks Sayers has commenced business as a consulting and electrical engineer at Birmingham. This gentleman is well-known in electric lighting circles in London his connection with this industry being of long standing.

NOTES.

ALFORD.—Tenders are asked for lighting the town of Alford "with gas or other light." Particulars may be obtained from the town clerk.

OUR AMERICAN COUSINS.—CORRECTION.—In our last week's leading article the date of the foundation of the Society of Telegraph-Engineers was given as 1878. It should have been 1871.

SOFT STEEL FOR COMMUTATOR BARS.—In the description of an electro-motor designed in the United States by Mr. F. Baxter, we find that the commutator bars are made of soft steel instead of copper.

THE MONTMARTRE CENTRAL STATION.—The central station of the Compagnie Francaise d'Eclairage Electrique, in the Faubourg Montmartre, Paris, commenced operations at 9:30 p.m. on the 21st inst.

PROJECTED TELEPHONE LINE BETWEEN HAVRE AND ANTWERP.—Suggestions for long distance and international telephone lines continue to multiply across the Channel. The latest proposal is for a line between Havre and Antwerp.

EXETER.—It is stated that an electric lighting company is about to make a start at Exeter. Water power is to be used, and the company proposes to light a number of main streets gratis for several months. We presume that the Thomson-Houston system is the one alluded to.

TENDERS WANTED.—Tenders are asked for the supply of telegraph material and apparatus, including galvanised wire, by the Highland Railway Company. Forms of tender may be obtained on application to Mr. J. G. Bulmer, storekeeper, Inverness, and must be returned by the 25th inst.

TRANSFORMERS IN THE STATES.—The Westinghouse Electric Light Company, Pittsburgh, Pa., has received the contract for a large transformer plant to be erected at Denver, Col., and to consist of 6,500 lights. The station will be supplied with five dynamos, with a capacity of 1,300 lights each.

SCIENCE AND THE JUBILEE HONOURS.—This is a chapter of "Snakes in Iceland." The Royal Society received six tickets for the service at the Abbey, and this is all that can be said—so far, at least—for the recognition which has been accorded to the representatives of Physical Science on the Jubilee of Queen Victoria.

OBITUARY.—We regret to record the death, at the age of 76, of Colonel Alexander Agnus Croll, of Beechwood, Reigate, who was one of the pioneers of cheap telegraphy. At the time of the transfer of telegraphic business to the Post Office, Colonel Croll occupied the position of chairman of the United Kingdom Electric Telegraph Company.

DAMASCUS.—The Governor-General of Damascus is busy with plans for laying tram lines through the streets of that ancient city. It has afforded us pleasure, therefore, to send His Excellency certain copies of this journal, which set forth the advantages of electricity over other forms of locomotion for the purpose in view. The population of Damascus at the present time exceeds 200,000.

ROTTERDAM.—Messrs. R. E. Crompton and Co., on behalf of their agents, Messrs. J. Van Zwieten and Co., have contracted with the Dutch Government to deliver a complete search light plant for the torpedo launch "Batak." We are also informed that the plant supplied by the same firm for lighting the brewery of Messrs. Boartz and Sons at Rotterdam is to be extended so as to light the whole range of buildings.

THE PATENT LAWS.—In a paper read before the Institute of Patent Agents, on the "Compulsory Working of Patents," Mr. A. V. Newton, Fel. Inst. P.A., argues "that the provision for the compulsory working of patents is a mistake, because it discourages inventors from rather than urges them towards the establishment of new branches of manufacture, by destroying the incentive to foreign inventors to create a demand for imported inventions."

ASBESTOS DEPOSITS IN RUSSIA.—It is stated that extensive deposits of asbestos have recently been discovered in the neighbourhood of Orenburg, while near the Verkni Tagil ironworks is a hill called the "Sholkovaya Gora," or Hill of Silk, which is stated to be largely composed of asbestos. The mineral is said to be of the best white quality, and adapted for all important purposes to which asbestos is applied. In the Goroblagsdat district of Perm, similar deposits, it is said, crop above the surface.

THE PROPOSED ELECTRIC LIGHTING OF BUCHAREST.—A Bucharest correspondent of a daily paper says that the negotiations carried on for some time between the gas company there and the municipal authorities have fallen through. The municipality favours the idea of introducing electric lighting, for the production of which a fall of water near Cotroceni would afford motive power. Before coming to a definite decision, however, the authorities have consulted a German engineer, and at present they are awaiting his report.

THE JULIEN TRAM CARS AT HAMBURGH.—In another column will be found an extract from an interesting and encouraging report of the cost of working the Hamburgh tram lines by means of Julien storage cars. This report is based upon a careful record of the expense during the eight months ending in December last. But according to a statement which we recently quoted from the *La Lumière Electrique* the system has now been or is about to be abandoned altogether. We should be glad to learn the truth upon this point.

MENDING INCANDESCENT LAMP FILAMENTS.—M. Pauthonnier has succeeded in repairing the filament of a large number of incandescent lamps, at a cost which is said not to exceed 2f. per lamp. His method is to open the lamp with great care, so as to prevent a too sudden rush of air, which would shatter the glass, and then to displace the air by a dense hydro-carbon. The broken ends of the filament are brought into contact, and a current is sent through which causes a deposition of carbon sealing up the joint and strengthening the filament throughout its length. It would, however, seem that the process must necessarily tend to lower the voltage of the lamp.

A NEW RELAY.—A very simple and sensitive relay has been designed by M. Lahmayer, the construction of which will easily be understood from the following description:—A glass tube closed at both ends is about half filled with mercury, and contains a piece of iron rod nearly the full width of the tube, which floats in the mercury. A pair of platinum wires enter the glass just above the normal level of the mercury, and are connected with the circuit to be closed by the action of the relay. The glass tube is placed within a solenoid traversed by the current in the first circuit. The iron float is sucked down by the solenoid; the mercury rises and closes the circuit through the platinum wires. To avoid the oxidation of the surface of the mercury by the spark on breaking contact, the upper part of the tube is filled with nitrogen.

THE ELECTRIC LIGHT FOR THE FRENCH ARMY.—A portable electric light apparatus has been for some time in use in the German army. For the field equipment the dynamo, engine, and projector are mounted upon a carriage drawn by several horses, and a stationary apparatus of the same character has been

Digitized by Google

supplied to most of the fortresses on the frontier. It is announced, however, that the French Government has decided to adopt a far more powerful light, and the optical arrangements of the projector are designed especially to produce the most dazzling effect upon the eyes of the troops upon whom the beam is directed. The carriage upon which the apparatus is mounted is also provided with a gun whose special function will be to fire at the lamps of the enemy while their light is overpowered by the more brilliant beams of the new projector.

THE COST OF ELECTRIC LIGHT AT SALZBURG. — The *Electricitätswerke* of this town have issued the following scale of prices for the supply of the electric light :—For 16 candle-power incandescent lamps about ·94d. per hour; 25 ditto, 1·47d.; 35 ditto, 2·00d.; on which a discount will be allowed varying from 5 to 25 per cent., according to the number of hours per day that they are in use. For arc lamps the prices are :—From 400 to 500 candle-power, 2·82d. per hour; 600 to 700 ditto, 4·23d.; 800 to 900 ditto, 5 64d.; 1,400 to 1,600 ditto, 8·46d. It is intended to supply arc lamps in pairs only, and if a single lamp be required, double the ordinary price will be charged for it. The carbons will be supplied by the company, and will cost about ·705d. per lamp per hour. The current supplied is to be measured by a current meter, to be approved by a committee appointed by the magistrates, and the yearly rent charged for these meters will be :—Up to 10 or 16 candle-power incandescent lamps, £1. 9s. 4½d.; 25 ditto, £1. 19s. 2d.; 50 ditto, £2. 18s. 9d.; 100 ditto, £3. 18s. 4d.—*Journal für Gasbelenchtung.*

THE NEW AUSTRIAN CUSTOMS TARIFF AND THE IMPORTATION OF DYNAMOS.—Owing to the operation of the new Austrian tariff, which came into force on the 1st inst., special precautions will be necessary, says *Industries*, in the importation of dynamos. As the tariff now stands, these machines, if imported complete and ready for work, will have to pay a duty of £24 per ton, the duty being calculated as if the whole of the weight were made up by cotton-covered wire. Such a duty would evidently be prohibitive, and, to avoid it, foreign manufacturers are permitted to import dynamo machines in parts, when each component part will be charged the duty according to the material preponderating in its construction. Machinery and apparatus containing by weight 75 per cent. of wood pay £5 per ton; machinery and apparatus containing over 50 per cent. of base metals other than iron or copper wire pay £15 per ton; other portions of machinery not containing wire pay £8. 10s. per ton. If machinery is imported in parts which require to be finished before being fitted up, it is taxed at a slightly reduced rate as compared to the above.

GLOBE LIGHTNING IN FRANCE.—In a note communicated to the Academy by the Minister of Posts and Telegraphs, some extraordinary events are described which happened in connection with a thunderstorm in the neighbourhood of Mortrée (Orne), on April 24th. A cow was being milked in a stable when the animal suddenly stood on its hind legs, jamming its fore-feet between the bars of the rack, and at the same instant the affrighted peasant saw a ball of fire enter the open door, pass between the legs of the cow, and disappear without explosion, and without damage. In the street outside the ground was at the same time thickly covered with fragments of a soft, greyish-white mineral substance, varying in size from that of a pea to a walnut. No analysis of the substance is given. During the same storm a length of 150m. of telegraph wire was destroyed, the wire being broken up in numerous short fragments. The discharge entered the telegraph office at Mortrée, and passed to earth through the lightning protector with a tremendous detonation, but without doing any damage whatever. At the same time a portion of the discharge seems to have passed through the brick wall of the house, perforating several holes, and hurling a quantity of plaster to the other side of the road.

THE "ECLIPSE" PORTABLE ELECTRIC BATTERY.—The following paragraph has been sent us for insertion, but as we have had no opportunity of inspecting the battery for ourselves we are not in a position to endorse the superlatives made use of:—"On Saturday last a number of gentlemen interested in electric lighting met at the offices of Mr. J. J. Walsh, White House, Telegraph-street, to witness the capabilities of this new and valuable battery, which, with its low-resistance lamp, has already been tested with the most gratifying results on the Great Western Railway and elsewhere. The lamp is suitable for domestic illumination, and is the safest and most economical electric light in existence. It is also adapted for railway signals, private carriages, omnibuses, &c. The battery will also provide motive power to drive a sewing machine, or to do any little service of the kind. Above all, the apparatus is conspicuous as a miner's safety lamp, and only weighs 4lb. or 5lb. The battery is charged with the simplest ingredients, viz., sulphuric acid and common soda, and while the battery and lamp may be obtained for a few shillings, the cost of the charge is only 2d., and it will last for 24 hours. For simplicity and cheapness it is unapproachable."

AN ELECTROMETER DESIGNED FOR INDUSTRIAL APPLICATIONS.—A note by M. J. Carpentier, in the *Comptes Rendus*, describes a form of electrometer specially designed for industrial application. We may, however, premise that one of the types of the instrument bears some resemblance to the form designed by Mr. Arthur Wright, and which has been in use for some years at the Brighton central lighting station. The advantages claimed by M. Carpentier, and which are also strikingly apparent in Mr. Wright's instrument, are extreme sensitiveness combined with a remarkable dead beat action. M. Carpentier takes a pair of metallic concentric cylinders, divided into four quadrants, which are connected oppositely by pairs in the usual manner. Between the two split cylinders hangs the "needle," which also takes the form of a pair of opposed cylinder quadrants, and is made of thin brass delicately suspended by a fine wire. In another form the cylinder quadrants are placed horizontally, and the "needle" is balanced on knife edges. The couple acting upon the needle is then opposed by the force of gravity. It is this form which resembles Wright's instrument. Quadrant cylinders, in lieu of discs, were introduced for electromoters by Dr. Edelmann, of Berlin; but M. Carpentier is, we believe, the first to employ the device of a pair of concentric cylinders. In order, however, to obtain a still more dead-beat effect M. Carpentier has carried the idea a step farther. He employs quadrants of soft iron, and places them between the poles of a strong permanent magnet. By this means the "needle" moves in a strong magnetic field, which so rapidly checks its tendency to vibrate that almost perfect aperiodicity is attained. It may be anticipated that with the increasing employment of alternating currents instruments of this kind will come into extended use.

THE EDISON-SWAN COMPANY'S MINING LAMP.—At the usual monthly meeting of the members of the Manchester Geological Society last week Mr. John S. Burrows (hon. sec.) showed a portable electric lamp for mining purposes, which has just been introduced by the Edison Electric Light Company, and which had been tried with what was described as the most satisfactory results at the Atherton Collieries. The

Digitized by Google

lamp consists of a small strong wooden case, suspended by a strap which contains an accumulator and an incandescent lamp combined, the whole weighing about 7lb.; the cell is said to be capable of maintaining a light of 2½ candle-power for about fourteen or fifteen hours. The lamp is arranged in front of the accumulator with a concave enamelled reflector behind it, and a thick plate of glass in front to protect it. The whole apparatus is kept within a sufficiently small compass, about 7in. by 5in. by about 4in. Mr. Burrows stated that the lamp gave a better light than four Marsaut lamps, and he did not find the weight any inconvenience, as the electric lamp could be carried in any position as found convenient. Mr. J. R. Williamson (representing the Edison Company), in reply to questions, said the cost of working the lamps would be very little, as the dynamo for charging the accumulators could be driven by the colliery fan engines, and the lamps charged in the night time ready for use the next day; he did not think, however, that the lamps could be produced under 40s. each. With regard to the filaments in the lamps, they were liable to be shattered by a heavy blow on the lamp, but provision had been made to prevent the possibility of this as far as possible. The filaments were reckoned to last 500 hours before they required renewal, which was half the time allowed for lamps in ordinary use; but they had taken into consideration the rough wear and constant use in a colliery. During the discussion which followed, the general opinion was that the cost of the lamp would be a serious drawback to the general adoption throughout a colliery; but it was suggested that stations might be fitted up with them in various parts of a colliery, where they would be available in the case of an accident which had put out the men's ordinary safety lamps, whilst for exploration purposes after an explosion they would be very valuable.

Méserolé's Three-Volt Accumulators.—We mentioned recently the rumour that the electrical world would before long be astonished by the advent of a secondary battery possessing an E.M.F. of three volts per cell. We find some further information as to this important event in the *Bulletin des Société Electrique*. One naturally feels sceptical as to the validity of a claim of this character, although we should hesitate as yet to pronounce a definite opinion. The plates of this remarkable cell are now said to consist of zinc and of lead, and the solution is made up of sulphate of mercury, sulphate of zinc, and free sulphuric acid. When the battery is charged by sending a current from the lead to the zinc an amalgam of zinc and mercury is deposited upon the latter plate in the form of a thick though porus layer. The lead plate is, of course, oxidised: On discharge, according to the inventor, an E.M.F. of three volts. per cell is obtained. M. Méserolé explains the reaction as follows:—"During the charge the amalgam which is deposited upon the zinc plate carries with it nearly the whole of the liberated hydrogen, for when the cell is in good order no hydrogen is given off either in charge or discharge. In the discharge a portion of the occluded hydrogen combines directly with the excess of oxygen upon the negative plate, as in a Planté cell. But a more complex action also takes place. The deposit of zinc and mercury is re-dissolved, and the zinc displaces a part of the mercury in the sulphate which has remained in solution. The mercury in its turn displaces hydrogen from the free acid, and the hydrogen deoxidises the lead peroxide. A part of the mercury set free also probably combines with the oxygen on the negative plate. The E.M.F. will thus be equal to that developed by the zinc in replacing the mercury in the sulphate, plus that due to the action of the free acid on the liberated mercury, plus that of the combination of hydrogen with the oxygen on the negative plate." Considering, however, that the chemistry of a simple Planté cell is still a matter of hot dispute, it is too much to expect that M. Méserolé's theory of the action of his cell will meet with universal acceptance. We are more concerned at present with the practical question whether the three volts per cell can be substantiated, and, if so, whether the cell is reasonably good in other respects. The latter question is one which only actual experience of some duration can finally answer; but if the cell can bear the test of practice, we need hardly say that the invention is one of very considerable importance.

The Incandescent Gaslight Company.—Some of our readers will be interested in the following comments on the affairs of the above-named company, which we reproduce from our contemporary the *Gas World*:—"The first statutory meeting of the Incandescent Gaslight Company (Limited) was held in London on Thursday last. The chairman, Mr. H. W. Blake, gave a *resumé* of the position of affairs, but he carefully abstained from any reference to the disruption in the directorate shortly after the company was formed, and before shares had been allocated to shareholders. It is evident, however, that the chairman and his co-directors are sanguine about doing a considerable business. They have started two manufactories in London for the production of burners; they have obtained a large number of burners from Vienna, and they have placed orders in England for 30,000 more. All this looks hopeful, and we wish the company every success, because the lines on which it proceeds are those which must eventually lead to the more extensive use of gas, not necessarily of high illuminating power, for domestic and public lighting. While we say this, however, we must guard ourselves against any appearance of pronouncing unqualifiedly in favour of the Welsback light. That it is pretty goes without saying, and that it reduces the vitiation of the atmosphere to the minimum is equally true; but there are certain considerations connected with the use of this lamp which destroy, for the present at any rate, any hope that it will be universally adopted. The price, for instance, must militate against its general use, and the annual charge for maintenance is more than most people will care to pay. Toy lights are all very well in their place, but what the users of artificial light desiderate is a cheap burner, or some other economical mode of using gas. The Welsbach light costs somewhere about 15s. to begin with; a further charge of 6s. a year is insisted on to keep the mantles in order; and then, after all, the best results in the way of incandescence of the mantle are not got with ordinary pressures; and doubts are entertained regarding the power of the mantle to steadily emit the same amount of light from the beginning to the end of its existence. The fragility of the mantles was referred to at the meeting on Monday, and Mr. Mactear, one of the directors, and, if we mistake not, a co-patentee, admitted that they were delicate. He did not in the least help his case when he made reference to the incandescent filament and the glow lamp. That filament is enclosed in a globe from which the air has been exhausted; no finger need ever touch it, and if it is destroyed, then this is due to the electrical currents and not to any other physical effect. Mr. Mactear gave instances of the durability of the mantle, but these were where they were under the control of the servants of the company. The public will not, we think, have much to do with a burner which is not only expensive to begin with, but which requires so much skilled manipulation."

The Influence of Magnetism upon Chemical Reactions.—This interesting subject is receiving a good deal of

Digitized by Google

attention at the present time, both in France and in Germany. In our last week's notes we called attention to observations of Dr. Gross, of Berlin, showing that a difference of potential is set up between plates of magnetised and unmagnetised iron immersed in dilute sulphuric acid. In the current number of the *Journal de Physique* there is an interesting paper on the same subject by M. Paul Janet. A simple theoretical explanation of this phenomenon is developed by M. Janet in the following manner: Suppose that we have a permanent magnet and a piece of soft iron, and imagine that the following cycle of operations is carried out while the magnet remains at rest:—(1) The piece of soft iron being supposed to be at an infinite distance, it is allowed to approach the magnet; let T be the work produced. (2) The soft iron is now allowed to enter into chemical combination with some other substance, sulphuric acid for example; let Q be the quantity of heat liberated. (3) The sulphate of iron thus found is removed to an infinite distance. If we neglect the magnetisation of the sulphate compared with the metallic iron, the work done upon the salt by this transfer is negligible compared with T. (4) We decompose the sulphate, so as to reconstitute sulphuric acid and metallic iron, and let Q′ be the quantity of heat absorbed. The cycle is therefore closed, and we can apply the principle of conservation of energy, so that we must have

$$T - E(Q' - Q) = 0$$

whence

$$Q' - Q = \frac{T}{E},$$

and as T is positive, $Q' > Q$, or, in other words, the heat of combination of iron is less in the magnetic field than beyond it. This explanation may be applied to the interesting experiments of M. Colardeau on the deposition of copper upon iron in the magnetic field. (See *The Electrician*, May 13th, 1887, p. 3.) The fact that the heat of combination of non-magnetised iron with sulphuric acid is greater than that of magnetised iron will tend to protect the latter from the attack of the acid in presence of the former. [It must, however, be remarked that the generalisation according to which that particular chemical reaction which evolves the most heat *always* takes place in preference to any other possible reaction is no longer admitted by many chemists, and has even been given up by M. Berthelot himself.] M. Janet concludes his paper with the remark that it results from these considerations that the E.M.F. of a cell of which iron is one of the elements should be diminished in a magnetic field, and he proposes to try to verify this conclusion by direct experiment.

GERMAN SILVER WIRE.—During the recent meeting of the American Institute of Electrical Engineers, among other incidental matter which our space will not permit us to report in full, a discussion of some interest took place on the qualities of different samples of German silver. The question arose out of a short paper by Prof. Anthony, who had found that the coils of a large resistance box had differing temperature coefficients. This particular set of resistances had been constructed some years before, by an eminent firm in this country, to a specification which required that the coils should check among themselves to ·01 per cent.; but owing to the above-named source of error it was found that the specification was only complied with for one particular temperature; almost every coil, in fact, had a distinct temperature coefficient of its own. Prof. Anthony thought that the error might have arisen in part from the wire not having all been taken from the same sample of the alloy, and also from the different degrees of strain in winding upon wires of different diameter, which would alter their molecular condition. He suggested that for fine instruments all the coils should be made of the finest wire required for the coils of highest resistance, and the lower resistances should be obtained by winding two or more of the same wires in multiple arc. Mr. Prescott said that while engaged on some experiments with Mr. E. Weston he had sought everywhere for information as to the exact proportions of German silver alloy as understood by the standard writers on electrical science. He had not, however, been able to discover a single textbook which gave the information—it was not even to be found in Matthiessen. He next made inquiries as to the practice of the various American makers, and found very little agreement amongst them. Mr. Prescott went on to say that together with Mr. Weston he had made experiments upon the alloy known as platinoid, which consists of German silver, with a little tungsten added. The resistance of this alloy is usually supposed to be higher and its temperature coefficient lower than that of German silver. But their experiments had led them to believe that the presence of tungsten had no real influence. They "made up some ordinary German silver, and put some tungsten into it, and kept on adding it up to 10 per cent., but it did not make any difference." They came eventually to the conclusion that the specific resistance of such alloy is almost directly proportionate to the amount of nickel present. By increasing the proportion of nickel and diminishing the zinc a resistance much higher than that claimed for platinoid could easily be obtained. But as the proportion of zinc was diminished the alloy lost its ductility, and the temperature coefficient decreased at the same time. With 30 per cent. of nickel the specific resistance exceeded three times that of the German silver of commerce, while the temperature coefficient was too small to be determined by the means their disposal. Mr. Wallace added that he had made large quantities of German silver and found it extremely difficult to get two samples exactly alike in their electrical properties; it depended not only on the composition of the alloy, but also on the temperature at which it was worked, and the way in which it was rolled, drawn, and annealed.

PHOTOGRAPHS OF LIGHTNING.—Last week we referred to the fact that the Council of the Meteorological Society are anxious to obtain photographs of flashes of lightning. The *Photographic News*, dealing with the conditions under which such photographs should be taken, notes the following points as important:—"First, the exact position of the camera. In many countries ordnance maps can be obtained on such a scale that a minute dot will indicate the position of the camera within a foot or two, and it will often be easy to record the position of the apparatus with far greater exactness, as, for example, when the camera is placed at a window. A thread with a plummet should be allowed to range from the optical centre (say the diaphragm in case of a doublet) to the floor, where a mark should be made. Second, the time at which the exposure was made. Third, the aspect of the camera. When the locality is exactly recorded this datum may be approximate, as there will generally be the means of exactly determining it upon the plate itself. Fourth, the equivalent focus of the lens, but the determination of this may well be left until it is found that something valuable may be deduced from the photograph. Fifth, the distance of the flash. The recording of this is a very important matter, as, when the focus of the lens is known, it will be easy to determine the actual distance between cloud and earth, and also the horizontal angle subtended to the observer at the camera. To determine the distance the observer should note as accurately as possible the time elapsing between the flash and the report, and in doing this even such a chronograph watch as may now be had for five or six pounds will be found of great service."

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 117.)

In Fig. 11 a diagram, made from experiment, is given, in which the diminution of self-induced E.M.F. towards saturation point of the armature core is clearly seen. The highest curve is drawn through points obtained by noting the E.M.F. with various exciting powers whilst running on open circuit, the lowest curve shows the E.M.F. when working with the full load of current on the armature for various exciting powers, and the intermediate curve is constructed by adding the constant Cr_a, where r_a is the resistance of the armature, to the experimental values depicted in the lowest curve; thus this intermediate diagram shows the total E.M.F. minus the counter self-induced E.M.F., and it can be easily seen that its horizontal tendency points to the same elevation as that of the highest curve in the values of which self-induction has no part.

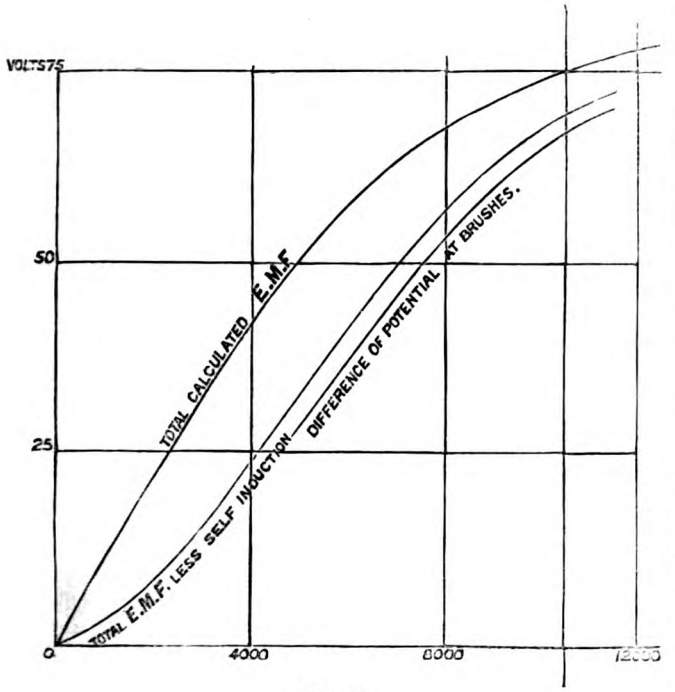

FIG. 11.

It is sometimes thought that the cross magnetisation, due to the static effect of the current in the armature, has some direct influence on the E.M.F., but this is not the case.

The effect of this cross polarity is simply to produce a distortion of the impressed field, which is driven round by it in the direction of rotation when the machine is working as a generator, and in the contrary direction when working as a motor. Fig. 12 is a diagrammatic illustration of the actions

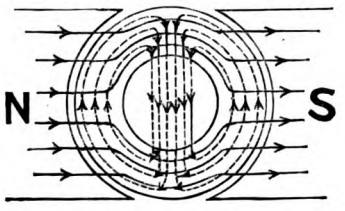

FIG. 12.

involved. Here it will be seen that the cross excitation due to the armature current would produce lines in the same direction as the impressed lines throughout one half of their path on each side of the collecting diameter, and in a contrary direction for the other half—thus the resultant effect of this excitation on the impressed field is *nil*. Also the E.M.F. induced by cutting these lines, were they actually to exist, would be *nil*, owing to the fact that they are cut in both a positive and negative sense on the same side of the collecting points.

Although it is only the E.M.F. induced by the cutting of those back lines which attend the reversal of current in coils on passing the neutral line, which is counter to the calculated E.M.F., yet the distortion of the field just mentioned has undoubtedly a prejudicial effect on the good working of the machine, and the reason of this seems to be partly because under these circumstances the collecting diameter is often brought so close to the edge of the pole shoe as to induce the lines to spring across more suddenly from the armature core than they would otherwise do. They are then cut more quickly by a very small movement of the coil than where a sufficient space intervenes. The difference of potential in a coil between the positions of collection and the angle made by one segment of the commutator with this diameter is then considerable, and sparking is therefore aggravated. Unless the segments in the commutator are extremely numerous, a large angle of distortion always points to a large amount of self-induction, so that a reduced E.M.F. often seems to be a characteristic of the distortion itself.

It was pointed out that the current reversal has to be accomplished in a definite time; this time is that required for the armature to turn through the angle covered by the surface of the brush upon the commutator, and if very short indeed, it may not be sufficient to admit of the natural fall and rise of the current; but since this must have its full strength at the close of the interval, a spark of more or less violence will pass at that moment to adjust the potential to its proper sign and value. Hence it is frequently found that thick brushes, or the device known as a slave brush, which consists of placing a second brush of similar sign, slightly in advance of the first, will materially reduce sparking in a machine of bad design. It must always be borne in mind that the effect of self-induction is to demagnetise the armature core, and therefore it is impossible to get a very high magnetic induction in a heavily wound core, having an insufficient number of parts in the commutator. This consideration should have due weight when fixing the ratio β, the value of which, as found by the curve of maximum work, should be modified if experience leads us to foresee that the self-induction would be too great. In well designed machines the E.M.F. of self-induction is seldom more than 3 per cent. to 5 per cent. of the resultant E.M.F.

Having followed the subject up to this point, the practical design of a concrete machine may be proceeded with, and since we are also seeking to make some comparison of the relative merits of the Gramme and Siemens machines as usually constructed, it will be advisable to work out the dimensions for these two, and also for the multipolar disc machine of the Gülcher or Victoria type to the same specification. The weights and sizes of those parts necessary to the electrical body of each of the three machines can then be tabulated. Such mechanical items as the bedplate, bearings, &c., could not be properly brought into this category, because they may evidently be subjected to any amount of modifications to suit the taste of the engineer.

Take then a 10-unit dynamo required to give 100 volts at the terminals, and 100 amperes, at speed of 1,000 revolutions per minute. We are not able to say at once what the electrical efficiency of such a machine will be, but we know by experience within one or two per cent., and shall be tolerably safe in assuming it at 90 per cent. In the same way it is necessary to assume the counter E.M.F. of self-induction. This we may take as 5 per cent. of the resultant E.M.F. The total upon which the calculation must be based will thus be

$$E = \frac{1000}{9} + \frac{1000}{9 \times 20} = 117 \text{ volts.}$$

For the first example we will take a cylinder Gramme ring, such as the Crompton, Kapp, Goolden and Trotter, &c., &c. machines, in which, referring to Fig. 6, No. 22, Vol. XVIII., the ratios will be fixed as follows: —

$q = 2$	$M = 20$
$p = \cdot5$	$\gamma = \cdot8$
$\beta = \cdot1$	$\mu = \cdot7$
$\rho = \cdot9$	

Digitized by Google

With respect to μ it should be remarked that, as its value depends upon the size of wire which is used, there is no certainty in fixing it to start with, but after having obtained a value to suit a particular machine, it is easy to approximate very nearly to the correct value, for it was shown that in an armature wound with a constant number of turns $C \propto R^{\frac{3}{2}}$, whence it is clear that the current density $D \propto R^{-\frac{1}{2}}$, but $EC \propto R^{\frac{5}{2}}$ with constant peripheral velocity; $\therefore D \propto EC^{-\frac{1}{5}}$.

The sectional area A is now determinant, and μ can thus be approximated. The core in such a machine as the one we are taking is built up with thin iron washers; the value for γ is therefore well within the mark at ·8.

From equation (4) we get

$$R = 3{\cdot}6 \times 1{\cdot}274 = 4{\cdot}59\text{in., say } 4\tfrac{5}{8}\text{in.,}$$

$$\text{also } N = \frac{E{\cdot}10^6}{2\,M\,p\,q\,\gamma\,n\,R^2} = 174$$

$$A = \frac{2\,\pi\,\mu^2\,R^2\,\beta\,(1-p-\beta)}{N} = {\cdot}0149 \text{ sq. in.}$$

The depth of copper on the inner winding $\mu\,\beta\,R = {\cdot}32$in., and this must now be divided into a suitable number of layers. If this number is made too small the cross-section A will be awkwardly divided, so as to make the depth of the strip greater than the width. This would introduce a serious difficulty in the winding. If, on the other hand, it is too large the parts in the commutator will become too few. In the present instance the happy medium will be struck by making three layers on the inside. The thickness of the strip will then be $\frac{·32}{3} =$, say, ·11in., and the width $\frac{·0149}{·11} =$, say, ·135in.

It is now possible to check the value assumed for μ, and we find $\frac{·135}{·135+·05} = ·73$, which is near enough to the estimated value. Should the check show a more serious discrepancy, we have from eq. (5) $R \propto \left(\frac{1}{\mu}\right)^{\frac{2}{7}}$, other things being equal; the value of R can then be altered in the ratio of $\left(\frac{\mu}{\mu_1}\right)^{\frac{2}{7}}$ where μ_1 is the corrected value.

In the same way N is altered in the ratio $\left(\frac{R}{R_1}\right)^2$ and A in the ratio $\frac{R_1^2\,N}{R^2\,N_1}$; the resulting value for μ will then be found to lie on the other side of the true value, so that all the quantities may be fixed between the two sets of values.

It is necessary that the number of turns N, after having been divided by the number of layers l on the inside winding, should still be a multiple of the number of poles P. The figure 174, which was obtained for N, happens to fulfil these conditions, but had it not done so it would have had to be altered, and the area of core section slightly modified to satisfy the equation

$$E = 2\,M\alpha\,.\,N\,.\,n\,.\,10^{-6}.$$

In the case in point, however, N constitutes the proper multiple, and the number of parts in the commutator are found to be

$$S = \frac{174}{3} = 58.$$

It will be as well in making calculations such as these to check the results at this point by the equation for the E.M.F. given above, only substituting $p\,q\,\gamma\,R^2$ for a, thus

$$(2 \times 20 \times ·5 \times 2 \times ·8 \times 21) \times 174 \times 1000 \times 10^{-6} = 116{\cdot}93,$$

which is correct.

Before leaving the design of the armature it is necessary to decide upon the disposal of the winding on the outside of the ring.

Whenever it is possible, it is always best to make the winding shallow on the outside so that the length of the air gap δ may be small. In calculating the number of wires which would lie around the periphery, however, it is not necessary to allow so much as ·05in. for insulation, because that space also contains an allowance for the driving arms of the armature; moreover, the wires can be packed more closely on the top than at the inside, where the manual operations are more difficult. ·03in. will therefore be quite enough to allow both for insulation (which should not exceed ·02in.), and also for a certain amount of latitude which is necessary to avoid jamming of the wires.

The perimeter of the ring in question is $9{\cdot}25\pi$, which, divided by $·135 + ·03 = 176$; thus the 174 wires will go on with ease in one layer. The practical winding of an armature with three layers inside and one layer outside is not a matter of any real difficulty, and when men are accustomed to what is termed "riding" they soon pick up any kind of winding.

(To be continued.)

TELEPHONIC INVESTIGATIONS.*

BY NELSON K. CHERRILL.

At the meeting of the Society of Telegraph-Engineers on the 24th February last the President asked that any members who were desirous of speaking should make their remarks as concisely as possible, the time for discussion being limited. As a stranger to the meetings of the society I did not like, under these circumstances, to occupy the time of the meeting with the following remarks, but having since committed them to paper, I am sending them in case you think them worthy of separate publication:—

If we form a loose contact between two pieces of carbon the resistance of the arrangement is lessened by a pressure which tends to tighten the contact, and is increased by a removal of that pressure. I believe this fact has been known for a long time. In 1878 Prof. Hughes showed by his discovery of the microphone that a loose contact placed in a state of vibration would modify a current passing through it at the time in a manner proportional to the vibrations, and I think I am right in saying that the conclusion was immediately arrived at that the "microphonic action" was due to variation in pressure.

That this is the commonly received view is beyond question; that it is so is shown by the design of all the instruments in common use, and by the theoretical explanations offered by Prof. Silvanus Thompson. It is this view which I venture to combat, and I trust to be able to show that, although variation in pressure undoubtedly produces variation in the conductivity of the joint, this variation is independent of, and has nothing to do with, the telephonic action by which speech, music, &c., can be electrically conveyed.

The difficulty which presents itself when we consider telephonic action as arising from variations in pressure is that on this assumption we must admit that pressure must be in some instances *both increased* and *diminished* at the *same time*. Let me be quite explicit. Let A B (Fig. 1) represent the diaphragm

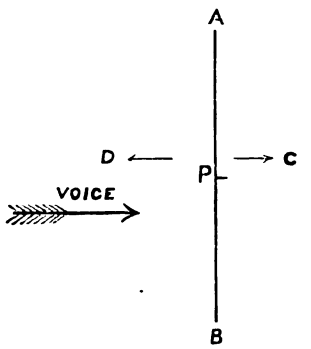

FIG. 1.

of a Blake transmitter. There is a platinum point shown at P. The voice comes from the direction indicated by the arrow.

* A further note on the recent discussion at the Society of Telegraph Engineers.

Digitized by Google

Now the *implied* explanation of the pressure theorists is that the waves of sound are "collected" by the diaphragm, and that the point P moves alternately in the direction C and D, increasing pressure as it moves towards C, and diminishing it as it moves towards D, the current being, of course, varied accordingly. This explanation is very simple when only a simple sound is given, such as the note of a tuning fork on the word "ah," &c.; but now suppose *two* sounds are given, the one being the octave of the two.

To produce the octave of any note the vibrations must be evidently twice as quick as those in the note itself; there must therefore be on the pressure theory twice as many increases of pressure in the one case as there are in the other. That is to say, the point P must, to produce the lower note, be at its extreme limit in the direction D at the same moment that to produce the higher note it is at its greatest distance in the direction C. In other words, the point P must be in two places at the same time, which is absurd; or, what is equally absurd, on the pressure theory, the current must to produce a note and its octave be both increased and diminished at the same time.

I know the common explanation of this and similar difficulties is that the movement of the point P is the resultant movement of all the sound waves on the diaphragm. So it no doubt is, but the "explanation" to me *explains* nothing.

If the current as modified by the transmitter is simply the "resultant" corresponding to the various pressures caused by the vibration of the diaphragm, how is the receiving instrument to know how to divide up the current so as to produce a like result at its end of the line? The idea seems to me much the same as if one should break up a column of type and send it in a box to a correspondent at a distant station. How is he to know how to recombine the letters so as to reproduce the ideas originally expressed by them?

Tyndall in his book on sound tells us that a resultant *tone* is a tone which corresponds to a rate of vibration equal to the difference of the rates of vibration of two primary tones, and he goes on to show that the resultant tone is always lower than either of the two primaries; hence hearing a note and its octave in the telephone cannot be explained by any suggestion that the tones heard are "resultant tones."

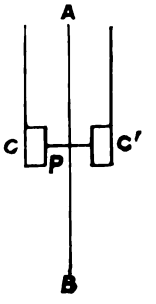

Fig. 2.

It is sometimes suggested that as with a stretched string—as in a violin—not only the fundamental note is heard, but also many harmonica and over tones, with only one constant movement of excitation to keep up the vibration, so, somehow or another, one set of movements in the diaphragm will cause different tones to be heard in the receiver; but I cannot see that the cases are parallel in any degree. In support of the idea that pressure variation is *not* the cause of telephonic action, I made an experiment which is very interesting, if not quite conclusive. I removed the little spring carrying the platinum point from a Blake transmitter, and substituted for it a piece of platinum wire, which passes straight through the diaphragm, and is soldered to it; the wire terminates in a point at each end, about a quarter of an inch from the diaphragm. I then hung in front of the diaphragm a second block of carbon, making the pressure as nearly equal to the original block as I could. The arrangement is represented in Fig. 2, where C C' are the two carbon blocks, A B the diaphragm, and P the platinum wire between the two blocks, soldered to the diaphragm. I led the current from C through P to C', and thence to the transformer.

The object in this arrangement was to make the diaphragm vibrate between the two carbon blocks, so that if we were working by pressure the increased pressure on C' should occur at the same moment as a diminished pressure on C, and *vice versâ*. I thought, if the pressure theory were correct, such an arrangement should *not* act telephonically, as the pressure and diminution of pressure should neutralise each other. To avoid any suspicion of C being *driven on* to the diaphragm by the same air waves that drove the diaphragm itself on to C', I *conveyed* the vibrations to the diaphragm by means of a wire which pressed against it at one end, and against the case of a small American clock at the other. With this arrangement I found I could detect no difference in the clearness with which the sounds were conveyed, whether the current was led from the diaphragm to C', as in the ordinary way, or from C to C' as described, and I thence conclude that as the pressures and diminutions of pressure between C and C' did not *neutralise* the currents they (the pressures) could not have been the immediate governing conditions of the current strengths. I am aware that this experiment is open to the criticism that to amount to a demonstration it would be necessary to show that the conditions on each side of the diaphragm are exactly alike in all points.

In making the actual experiment I put a contact key between C and P in such a manner that the one microphone could be short-circuited out of action without otherwise disturbing the arrangement. The sound in the receiver was *louder* when only one microphonic contact was at work, as would be expected, because so much less resistance would then be offered to the battery current (one cell of bichromate); but the sounds were equally *distinct* with the two contacts as with one. The scraping of the wheels, the clang of the spring, and all the host of sounds which go to make up the tick of a clock, were reproduced with equal clearness in either case.

There is another point, however, in favour of the view I am taking, which is, that with some at least of the commercial telephones, if the pressure theory is correct, the sibilant sounds ought to neutralise themselves. Mr. Preece tells us that the sibilant sounds go up to 4,000 or 5,000 vibrations in a second. The longest of these gives a wave length of ·275ft., or say about 3⅜in. The half of the wave length is evidently the distance between greatest and least pressure, so that any telephone transmitter having many microphonic contacts, may very well have some of them 1¾ distant from each other, and in such a case a sibilant tone of the above mentioned velocity ought to neutralise itself if it come in the direction of the line joining the two contacts. Practically, any transmitter of many contacts ought, on the pressure theory, to cause interferences, more or less, with the higher notes, according to the distances of the contacts from one another and the direction of the sound waves. I have not heard of the case of any such interferences having been actually observed, though Prof. Silvanus Thompson seemed anxious to provide against them when he stated in describing his transmitter of 108 microphones that "the impulses do not, of course, pass down the steel rod absolutely instantaneously, but the retardation of phase of even the shrillest of vocal sounds is quite negligibly small."

But is not the instrument devised by Prof. Silvanus Thompson himself, the "Valve," or ball transmitter, one of the best means of refuting the doctrine that telephonic action depends on variation of pressure? In describing the instrument Prof. Thompson says:—"The loudness of the valve telephone is limited by the fact that it is not expedient to work with more than three contact points, the limit being a natural geometrical one," by which, I take it, he means that a spherical surface will rest naturally with equal pressure on three points, and that it is extremely difficult, if not impossible, to make it rest on more points with equal pressure on all of them. It is obvious that the pressure on the three points will be, roughly speaking, equal when the instrument is at *rest*, but as soon as spoken into the case becomes widely different. Prof. Thompson, in his explanation, says the ball or valve "*rides* on the vibrations of the air waves." That may be so, but it can hardly be pretended that the valve whilst so "riding on the vibrations" maintains an equality of pressure on all its supporting points! It would appear that the very idea of "riding on a vibration" involves

Digitized by Google

lateral as well as vertical movement, and, if so, the pressures in the supporting point would be constantly *varying*; and, moreover, the ball would be approaching some of the contacts at the same time that it was receding from others of them. If, then, microphonic action is due to *pressure*, the valve telephone as described would produce sometimes one, sometimes two, and sometimes three distinct and separate interpretations of the same note, depending on the phase of vibration which the ball happened to occupy with regard to its three supports. As this is not the case, I think we may again conclude that telephonic action does *not* depend on variation in pressure, inasmuch as with the valve telephone vibrations of the same values are transmitted through contacts of obviously various pressures.

The very curious and interesting observation given by Mr. Stroh, in which he found the *timbre* of the sound transmitted by a microphone was altered by the adjustment, admits, I think, of another explanation than that put upon it by that gentleman. He finds the first contact of the two carbons is generally followed by a burning, which is, no doubt, the removal of the rough excrescences of the carbons by the heat developed in them by the current. If after this burning it happens that the carbons touch over a sufficiently large area, the current will pass silently and without any undue development of heat; but it is also easy to see that if the carbons happen to meet, say on the top of a little nodule, this may get very hot in carrying the current (though perhaps not hot enough to harm); the heat produced may by longitudinal expansion throw off the other carbon, if, as is explained by Mr. Stroh, the adjustment is very delicate, and this action would produce a rocking motion in the same sort of way as in Tyndall's explanation of the Trevelyan rocker, which would continue till either the adjustment of the spring was altered or until the constant hammering enlarged the surface area of contact to that point at which the current would pass without giving heat enough to produce the effect. If this line of reasoning be correct it is obvious that the area over which actual contact is made in a microphone may be a very variable amount, and it is further obvious that with a given pressure a variation in the area of the contact will give a corresponding variation in the actual current sent through the instrument. The sounds transmitted by the microphone are heard *through the current*, and whether the current is large or small (comparatively) the microphone differentiates all the parts of the sound, but, according to some experiments I have made, the *timbre* of the sound heard in the receiver varies with the amount of current passing, and hence the explanation of the phenomenon alluded to by Mr. Stroh.

(To be continued.)

MICHAEL FARADAY.

At the instigation of Count Rumford the Royal Institution was founded towards the close of the last century. From its inception to the present time this institution has been regarded as one of the greatest centres of English science. Inseparably connected with it are the names of Young, Davy, and Faraday —the greatest of whom, in our estimation, was Faraday.

While the name of Young will ever be connected with physical research in relation to light, so that of Faraday will be connected with his researches into the hidden mysteries of electricity. Half a century ago Faraday was in the hey-day of his activity and success, and it seems, therefore, but just that we should recognise in him the leader of science most intimately connected with the accession to the Throne of Queen Victoria, whose Jubilee has just been celebrated.

It is with these feelings that we present to our readers the accompanying portrait of the late Prof. Faraday, and without in any way desiring to emulate his biographers, we may be allowed at the same time to give a slight *resumé* of the salient incidents in his career.

Amongst the philosophers of Europe who have risen into the first rank of eminence by sheer force of intellectual energy and personal merit alone, Dr. Faraday occupied the foremost position. Without "patronage" or "friends" he steadily progressed, from a comparatively humble origin, to the position of the first experimentalist in this country, and his discoveries and theories have not only laid new foundations in science, but he lived to see their application to the purposes of daily life so extended that, from the lowest to the highest, throughout the civilised world man has been benefited by his researches.

Dr. Faraday was born at Newington, Surrey, on the 22nd Sept., 1791, and his early education was limited to the ordinary routine of private schools. At the age of 13 he was apprenticed to a bookbinder, but he speedily gave evidence of a taste for scientific matters, and his earliest experiments in electricity were the germ of pursuits that have resulted in discoveries connected with that science through which its theories have been completely revolutionised, whilst its applications in telegraphy, electro-plating, and electric lighting, have been of invaluable benefit to commerce and society in general.

The young student had the good fortune to hear some lectures, delivered by Sir Humphrey Davy at the Royal Institution in Albemarle-street, in February, March, and April, 1812. He took notes, and, amplifying them with remarks, drawings, &c., sent them to Sir Humphrey, who kindly replied to the letter, and early in the following year offered him the situation of chemical assistant under himself and Dr. Brande. Faraday shortly afterwards entered on the duties of his new position, and went to reside at the institution, where he subsequently spent, with but trifling exceptions, the greater portion of his life. Shortly after entering upon his engagement he travelled as assistant with Sir Humphrey Davy in various parts of the Continent, and in April, 1815, returned to the Royal Institution.

It would be impossible in our limited space to detail the various discoveries and researches which occupied Dr. Faraday during half a century. The whole subject of electricity and magnetism, which had hitherto been entirely in the empiracal stage, underwent systematic investigation by Faraday, and the secrets of nature gave themselves up to his researches, with results which are made known to the world in the various series of "Experimental Researches" published in the *Philosophical Transactions* of the Royal Society. "Electric Induction," "Magneto-Electricity," "Electro-Chemistry," "Dia-Magnetism," &c., successively formed the subjects of extension of the series. With respect to these we cannot refrain from remarking that they form admirable models and lessons to the tyro in science, not only in respect to the subjects on which they treat, but also on account of the rigid Baconian method—of experimenting *first* and theorising afterwards—which is followed throughout. In no part is imagination allowed to override scientific induction. If a theory be offered, the steps which led to its promulgation, and the reasons proposed for its adoption, are laid out with almost Euclidian precision. Had we more instances of such cautious, painstaking methods amongst philosophers of the present day, science would have less frequent reason to mourn the obloquy that too frequently follows the explosion of fantastical theories, based on limited knowledge, which at times are hastily emitted by less careful individuals than the one who is the subject of this memoir.

In connection with chemistry Dr. Faraday took the mantle of his great predecessor, Davy, and in developing the relations of electricity and chemistry, especially in regard to the laws of electrolytic action, he not only fully elucidated that of which Davy was the originator, but carried on these investigations to a much further extent. His experiments in another branch of chemical science—the condensation of gases—are of deep interest, and incidentally threw much light on the laws of latent and specific heat. In optics he first pointed out the relations of a polarised ray of light in regard to magnetism; the discovery of "heavy glass" in 1829 afforded him a material which was of the utmost value in the study of those phenomena. The general result of his discoveries in this and allied subjects leads to the belief that heat, light, electricity, and magnetism may be regarded as the development of *one* force, in a special form, rather than as individual forces acting on matter independent of each other.

Digitized by Google

From the year 1827 up to the period when failing health and increasing age caused the withdrawal of Dr. Faraday from active public engagements, he regularly delivered lectures at the Royal Institution. In 1833 he was chosen Fullerian Professor of Chemistry by the founder of the chair, the intention being expressed that he should continue to hold the position as long as he remained connected with the institution, without being required to deliver lectures, and solely in consideration of the value of his researches to the cause of science. His lectures to young people, given during the Christmas vacation, were distinguished by simplicity of style, just as his scientific researches are characterised by depth and philosophical exactness, and in their published form have been read and admired by a large class of readers.

That honours were largely conferred on Dr. Faraday would be naturally expected. In 1823 he was elected a corresponding member of the Academy of Sciences of France; in 1825 he was chosen a Fellow of the Royal Society, and in 1832 the University of Oxford conferred on him the degree of Doctor of Civil Laws. He was also one of the eight Foreign Associates of the Imperial Academy of Sciences of France; a Commander of the Legion of Honour; and a Knight of the Prussian Order of Merit. For his important discoveries Lord Melbourne's Government assigned him an annuity of £300 in 1835. He was a member of numerous scientific societies of this country, the Continent, and America.

His life, until he entirely gave up scientific pursuits, was one of constant devotion to experimental philosophy. But at last the strength of mind of this great philosopher became weakened. In the retirement of his quiet residence at Hampton Court, placed at his disposal by Her Majesty, he ended his days, almost excluded from the world. His death took place on Sunday, August 25, 1867, and his remains were interred at Highgate Cemetery the succeeding Friday, followed by a few personal friends who had long known and loved him.

A NEW METHOD OF MAINTAINING THE VIBRATION OF A PENDULUM.

A recent number of the *Comptes Rendus* contains a note by M. J. Carpentier describing a method of maintaining the vibrations of a pendulum by means of electricity, which differs from previous devices of the same character, in that the impulse given to the pendulum at each vibration is independent of the strength of the current employed, and that the pendulum itself is entirely free, save at the point of suspension. The vibrations are maintained not by direct impulsion but by a slight horizontal displacement of the point of suspension in alternate directions.

This, as M. Carpentier observes, is the method which we naturally adopt in order to maintain the amplitude of swing of a heavy body suspended from a cord held in the hand. The required movement of the point of suspension is effected by means of a polarised relay through the coils of which the current is periodically reversed by the action of the pendulum, in a manner which will presently be explained. The armature of the relay oscillates between two stops whose distance apart is capable of fine adjustment.

It is clear, therefore, that the impulse is independent of the strength of the current in the relay provided that the armature is brought up to the stop on either side. The reversal of the current is effected by means of a small magnet carried by the bob of the pendulum, and which as it passes underneath the point of suspension is brought close to a soft iron armature, which has the form of an arc of a circle described about the point of suspension. This armature is pivoted at its centre, and thus executes vibrations synchronously with those of the pendulum. These vibrations are adjusted to a very narrow range, but are sufficient to close the contacts of a commutator which reverses the current at each semi-vibration of the pendulum.

The beauty and ingenuity of this device will readily be appreciated.

ELECTRIC ILLUMINATIONS FOR THE JUBILEE.

(*Continued from last week.*)

The Electrical Power Storage Company were practically working day and night for some weeks, in order to cope with the demands made upon their resources for supplying temporary installations of the electric light during the Jubilee celebration. A great deal of their business consisted in providing illuminations for balls, receptions, &c., amongst others being those for H.R.H. the Prince of Wales, the Duke of Westminster, the Duke of Leeds, the Earl of Rosebery, Lady Henniker, &c. Of the outdoor installations which the company put up may be mentioned those for Downshire House, Belgrave-square, where the lights were arranged in festoons and rows over the portico, creating a very pretty effect, and for Queen Anne's Restaurant, Cheapside, where the outline of the front of the building was brought into strong relief by a tasteful arrangement of incandescent lamps An unambitious but, nevertheless, exceedingly effective installation was that over the main doorway of the Bank of New Zealand, which came in for a great deal of public admiration. This was a device consisting of an electrically lighted transparency, worked by the bank's own permanent installation. To this company is also due the credit for the artistic illumination of the residence of Viscount de Stern, in Great Stanhope-street, W., with incandescent lamps in tinted shades, as well as the Magistrates' Club, 88, St. James's-street, S.W., where the lamps were cleverly placed, so as to set off to the greatest advantage the floral decorations of the building. Numerous orders for lighting rows of houses, gardens, &c., in the the West End of London, came to hand too late for execution.

The students of the School of Electrical Engineering and Submarine Telegraphy, Prince's-street, Hanover-square, set up a device in glow lamps forming the letters "V. R." on a background of white cotton wool, which produced a beautiful effect.

The Institution of Civil Engineers in Great George-street, Westminster, gave an electric light display worthy of the occasion. This was carried out by the Anglo-American Brush Company, and was one of the most conspicuous installations in the vicinity of Westminster. It consisted of 500 glow lamps, arranged two in series, each of 10 candle-power, and aggregating 18,550 watts, forming the device, "1837—1887—Her Most Gracious Majesty the Queen." The panels at the top of the building were also illuminated with another device, showing the name of the Institution, the whole being exceedingly effective. In connection with this installation it could not fail to be remarked how much superior to other illuminants is the electric light, especially for outdoor illumination, for while the effects of other devices in the neighbourhood were at times painfully marred by gusts of wind, that at the Institution of Civil Engineers—and, indeed, wherever electricity was used as the lighting medium—remained uniformly bright and steady.

Next to Regent-street and Piccadilly, Old and New Bond streets were, perhaps, most conspicuous in the West End for the variety and extent of their illuminations and other decorations, and as might naturally be imagined the Grosvenor Gallery occupied in this respect a prominent position. The front of the building was brilliantly lit up by electric incandescent lamps; whilst stretching from one side of the street to the other there were several rows of lights, from which was suspended a bust of Her Majesty, surrounded by numerous lamps of various tints. The company also contracted for a large number of installations over the extensive area which they ordinarily supply, notably, in Bruton-street and Regent-street. Like most other companies, the demands made upon them were greatly in excess of the capacity of their plant.

In the Strand and Fleet-street there was also a good deal of electric light illumination. But by far the most imposing of the installations to be seen there were those at the *Daily News* office and the Gaiety Theatre. For the former the Fyfe Main Electric and Construction Company were responsible. The windows of the building facing both Bouverie-street and Fleet-street were gaily decorated with flowers and evergreens, in the centre of which there was fixed a powerful arc light, the outlines of the windows being followed by variously tinted incandescent lamps.

That at the Gaiety Theatre was supplied from Messrs. Spiers and Pond's permanent plant, and consisted of a pretty device in the shape of a crown of variously tinted incandescent lamps surmounting the glass-covered way at the main entrance to the theatre. For design and richness of colour nothing could have been better, a a fact to which the crowds of people who passed to and fro both on Tuesday and Wednesday night frequently testified by vociferous cheers.

Our enumeration might, in fact, be indefinitely extended, for in all probability there was scarcely a single installation of electric light in all London but what contributed its share to the general display of public rejoicing.

THE JUBILEE.

Readers of this journal, we are glad to know, are scattered all the world over; but, being familiar with the English language, they will need no explanation or apology for our choice of a subject to write about to day. In point of fact it is not so much a deliberate mental choice as an involuntary physical necessity that compels us to say something of the JUBILEE. The air of the British Metropolis has been full of it for months past; at the close of the present week our ears are still ringing with the echoes of Tuesday's festival, and our eyes still aching with the reflections of its splendour. On a quite commensurate, if not on so magnificent a scale, these tokens of rejoicing have been repeated throughout the whole country, and the telegraph has already told us that our brothers in far-off lands have enthusiastically done their part. Much less than fifty years ago—nay, less than twenty—it would have taken as many days as it now takes minutes to bring this gratifying news home to us, and the beacons which were set burning on every hilltop would have been a stern practical necessity half a century ago, instead of a mere pleasant revival as they were last Tuesday night. In the year of Jubilee as originally conceived the acquisitions of fifty years were returned to their former owners amidst the blowing of many trumpets. If in this year of grace we were required to undo all that we have done, and to give back the possessions we have wrung from nature since 1837—to say nothing of those we have appropriated in more questionable fashion—the result would be satisfactory to nobody, and the trumpeters hard to find.

In these days we are far more disposed to trumpet every addition to our store of material wealth; and when a jubilee happens to occur in the reign of a sovereign, as it has just now, one of our ways of showing jubilation is to reckon up the gains afresh and proclaim them with a very loud flourish indeed. After all, this is the most sensible plan, and, in fact, the only feasible one, the other being a pious aspiration which it is nowhere recorded was ever put into practice. We need not discuss it, therefore; but, for all that, it may very well serve to remind us of a certain moral duty which we might easily discharge on occasions like the present—the duty, namely, of acknowledging our obligations to men and things that have contributed to make the period of Jubilee one to look back upon with pride and congratulation. Our own humble contribution to the discharge of this duty—the one that seems to concern us nearest—is presented with the present number of *The Electrician*. FARADAY was a man whose memory we can recall with unfeigned admiration and reverence, and whose services to the electrical activities of the past fifty years we are bound to recognise with feelings of wonder and gratitude. We do not believe that we could have made a more appropriate choice among the scientific celebrities who have added lustre to Her Majesty's reign, though we may confess the inadequacy of the offering. Still, it is something, and our readers, we are sure, will accept it as a Jubilee memorial of peculiar interest to them. FARADAY's work will never die; his picture may serve to keep us mindful of the man who did the work.

It was the last thing in our thoughts when striking off this portrait of FARADAY to make any comments of a sort not jubilant, but it is difficult to repress all mention of the singular fact that, down to the moment of our going to press, there has been no public recognition of the part which science has played in the achievements of the half century, except the science of warfare, which, being aggressive and combative, never fails of its reward. Among the long list of names that have been honoured under advice by the Sovereign Lady of the land with promotions or distinctions there occurs none associated nearly or remotely with either Letters or Science or Art. We say singular, because we are not disposed to call it by a more disagreeable epithet. It may be an oversight, or it may be the result of just that inexplicable state of mind in high quarters which at first allotted the Royal Society exactly one ticket for the Jubilee service at Westminster Abbey. This was really very odd in more senses than one; and we cannot pretend to explain it except by a supposition which would be anything but flattering to the other recipients of royal favours. Perhaps it is assumed that the votaries of the arts and sciences pursue their vocation without desire or expectation of reward. Let us hope that they do, for then, verily, they will not be disappointed. It is a drawback to the aristocratic institutions of this country that no man can get a handle to his name who has not first put money into his pocket. This is perhaps as it should be, for a gilt handle on a poor vessel would only make it look (and feel) the poorer. But where poverty is a bar to military distinction, promotion always remedies the defect; and we see no reason why the same practice should not prevail for the arts of peace. At all events, we could invite them to share in a Jubilee festival, and even scatter a few C.B.'s, without much risk of discredit among the distinguished and deserving poor.

Despite of this seeming avoidance of public recognition, we are glad to observe that the Jubilee of the Telegraph will not be allowed to pass over without a fitting celebration. The Society of Telegraph-Engineers and Electricians, it appears, does not take up the matter in its corporate capacity; but we

Digitized by Google

learn that a representative gathering will be brought together some time next month to commemorate the first electric telegraph in a manner most agreeable to the tastes and inclinations of Englishmen, who always love to dine before testifying to their good humour. As regards the Electric Light, it has had its gala opportunity during these jubilant illuminations, and has come out of the ordeal, we must say, with flying colours. *The Times*, with its usual infelicity, has remarked upon the inartistic character of the new illuminant, apparently because some indiscreet persons used it in a theatrical fashion for casting beams of light across the housetops, and so marring the general grouping. It might as well complain of the domestic firegrate because the bonfires were extremely vast and lurid. From what we saw of places where the electric light was used we can confidently assert that for brilliancy of effect and colouring the oil lamps and gas lamps were nowhere in the competition. Wherever the electric current was employed, there unmistakably the colours were most beautiful and the light the most vivid.

THE JUBILEE OF THE TELEGRAPH.

We are glad to be able to announce that strong efforts are being made, and so far with great success, to suitably recognise the "Jubilee of the Telegraph." The normal English method of keeping anniversaries is to be followed on this occasion. It is proposed, therefore, to have a dinner on Wednesday, July 27th, when the POSTMASTER-GENERAL will take the chair, as representing the telegraphic interests of the Empire, and we understand that Mr. JOHN PENDER will be one of the principal guests, as representing the cable interest. United action from all branches of the profession, and co-operation from those interested in the theory of electricity as well as those more directly interested in its practical application, should make this a red letter day in the annals of electrical science. Further details will be given as soon as possible; meanwhile we trust that all those engaged in electrical matters will lend their aid to make this meeting a grand success. In addition, we may state that in all probability the annual *conversazione* given by the President of the Society of Telegraph-Engineers will be held on Monday, July 25th, so that the week may be looked upon as one celebrating the inauguration of the most wonderful of all the developments of modern science.

CORRESPONDENCE.

NOMENCLATURE—MAGNETIC RESISTANCE, &c.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As there is at the present time at least a possibility of the various words I have proposed coming into general use, I take the opportunity of making a few casual remarks upon the subject supplementary to those of 1885 and since. First, I observe on p. 114 (June 17) that you mention that I disapprove of "magnetic resistance." This is only a part of the fact. To illustrate this, I may say that were I investigating the theory of the dynamo, I think I should make use of the term myself, provisionally. What is really my objection is to its permanent use. There must always be a certain latitude allowed to investigators who do not find words ready to meet their wants. Were it an isolated question, there would be little difficulty in finding a perfectly unobjectionable word; but it is not an isolated question. My aim has been to make a scheme which shall be at once theoretically defensible and yet thoroughly practical. Bearing this in mind, I prefer to leave a blank in the place of "magnetic resistance" at present.

To illustrate the difficulties connected with nomenclature I may mention that last summer I was extremely in want of a term which should be an extension of impedance. The impedance of a circuit at a given frequency (under stated external conditions) is quite definite (with occasional departures due to want of proportionality between forces and fluxes), if it be a simple circuit, or reducible to a simple circuit, so that the strength of a current does not vary in different parts. But when it does we can certainly only legitimately apply the term impedance at the seat of the impressed force, if at a single spot; or else, if it be wholly localised in a part of the main circuit in which the current does not vary, then the term impedance is applicable. Now, I used impedance in an extended sense, but expressly stated that it was only done provisionally. I have since found a far better way of expressing results, viz., in terms of "attenuation" and "distortion," both very important things. The idea of attenuation, expressed in a more roundabout manner in terms such as diminution of amplitude, and so forth, is nothing new; the *word* "attenuation" I found Lord Rayleigh use, and at once adopted it myself as the very thing I wanted. "Distortion," on the other hand, I chose myself as preferable to mutilation and similar words. Its meaning is obvious. Make current variations in a certain way at one place. If the current variations at another place are similar, no matter how much attenuated they may be, there is no distortion. The extremest kind of distortion is to be found on Atlantic cables. Drawn on the same scale, there is little resemblance between the curves at one end and at the other. Telephony would be obviously impossible even were the frequency allowable to be sufficiently great, which is of course out of the question under present conditions. But only make the distortion reasonably small at a sufficiently great frequency and telephony is at once possible, provided the attenuation be not of unreasonable amount. (Frequency is Lord Rayleigh's word for "pitch," number of waves per second.)

Magnetic resistance again. A certain person once declared that $E = RC$ to express Ohm's law was nonsense; it must be $C = E/R$. This eminent scienticulist could not see the force of Maxwell's argument that electricity could not be a form of energy, because it was only one of the factors of energy. Now, however, through the development of the electric light rendering energy a marketable commodity through electric agency, there is not the least fear of converts being made to these views. So we may return to $E = RC$, or $C = KE$, if K be the conductance. One is just as good as the other, theoretically, and just as meaningful. Which to use (including the ideas) is purely a matter of convenience in the particular application that is in question. As a general rule, resistances are most useful, because we usually deal with wires *in sequence*. But if they be in parallel, conductances are the proper things to use. With condensers, on the other hand, permittances are most useful; should, however, we join in sequence, then elastances are the proper things. In theoretical investigations disconnected from special applications, the unit-volume properties conductivity, inductivity, and permittivity, are generally much more useful than their reciprocals, resistivity, (?), and elastivity. Now in late years there has been some development of practical applications in connection with the flux magnetic induction; in theory inductivity would be the most convenient basis; but several practical men find that the reciprocal ideas, say provisionally "magnetic resistivity" and "magnetic resistance," are most useful. I think their choice has been a wise one, whilst at the same time I recognise the difficulties they have to contend with, with "magnetic leakage," and so forth. It is for the practical men to find practical ways of getting a round peg to fit a square hole. They know best what they want, and whether empirical formulæ will not suit them better than more elaborate empiricism, which could be perhaps scientifically better defended. For it is clear that, beyond the region of proportionality of force to flux, the science of magnetic induction must continue very empirical for some time to come. I do not think the time has yet arrived for laying down the law by conventions or committees in this matter (as it may have come in from definite parts of electrical science); and that

Digitized by Google

practical and theoretical investigators should be allowed to develop their ideas freely. In short, Conventions or Committees should not meddle with matters (save very lightly) which are in a provisional stage. And I may add that, just as treaties are made to be broken, so the laws of Conventions (not the lords of Convention) will be broken as soon as ever it is found inconvenient to obey them. The introduction of anything of the nature of officialism into scientific matters should be strenuously opposed, in *this* country. It would be as bad as the passport system. The utility of a Convention seems to be to consist in the formation of a temporary consensus of opinion, from which to make fresh departures. There cannot be any finality.

Mac.—Here we are on firmer ground. There cannot, I think, be any question that this is the right name for the practical unit of inductance, in honour of the man who knew something about self-induction, and whose ideas on the subject are still to be fully appreciated. This was very much his own fault. He had the most splendid and thoroughly philosophical ideas on electro-magnetism all round, but kept them too much in the background. Maxwell's treatise requires to be *studied*, not read, before the inner meaning of his scheme can be appreciated. Had he lived he would probably, in some future edition, have brought his views prominently forth *ab initio*, and developed the whole treatise on their basis exclusively. Should the mac be 10^9 or 10^6 centimetres? If 10^9, which has great recommendations, then millimac will be practically wanted to avoid decimals. It is quite a euphonious and unobjectionable word.

Inductometer.—Naturally, in accordance with induction, inductivity, and inductance, a measurer of inductance (self or mutual) in terms of units of inductance, macs, or millimacs. I would apply the term to any instrument that measured inductance at once in terms of known inductances, as resistances are compared with known resistances. Some practical acquaintance with self and mutual induction, desultory, but of long continuance, has gradually forced upon me the idea (not to be easily displaced) that really practical ways of measuring inductances should be in terms of standard inductances, or, which is the same thing, by a properly calibrated inductometer, and not absolute measurements. What particular method of making the comparisons is best I do not know, nor yet how best to calibrate the inductometer. If it were a mere question of coils of fine wire, nothing is simpler or more expeditious or more accurate or more sensitive than the immediate balancing of the self-induction against that of an inductometer of *variable* inductance, using the telephone. The advantages and the simplicity are so great that I think practical men might well turn their attention to practical ways of extending the method to cases other than those in which mere coils alone are concerned.

"Absolutism."—The most absolute of all ways of finding the inductance of a coil is with a tape. Herein lies a moral of very wide application.—Yours, &c,

OLIVER HEAVISIDE.

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read several articles in your paper arising in the first instance out of the marked difference in the estimate for lighting Lord-street, Southport, and I trust the few suggestions I am about to offer may help to assist the matter forward.

I have long contended that for all installations of any importance it is unwise to go indiscriminately to a lot of electric light contractors—some good and some bad—and get an assortment of tenders for all kinds of different methods of lighting, some, like the contractors, good, and some bad. In my opinion if an installation is put to public tender a gentleman of known experience should be called in by the firm, company, or corporation, who require the light; he should be carefully informed in every detail as to where the light is required, about the necessary quantity of light, and should then prepare and submit a complete specification, drawn up in the form of a regular engineering specification, and this should be tendered to in all cases. I notice that "Plonmel" gives a table of areas illuminated by lamps of various candle-powers, suggesting that all tenders should be given on the equal basis of so much light per foot. Whilst I agree to some extent to his suggestion, it is apparent that in many cases such a rule could not hold good, because a uniform light for all classes of illumination is, in the first instance, incorrect; and, secondly, the contractors are then in about the same position as before, from the simple reason that if the artistic arrangement of the lamps is considered from different points, each tender would be on a different basis, so that I am firmly of opinion that there is only one real way out of our difficulties, that being, as I suggested before, to place the work into the hands of a reliable consulting electrical engineer. I say electrical engineer instead of electrician because so many men are electricians only and not engineers at all. It must be clear that it is not electrical knowledge only that is required, but a sound, practical engineering experience, which will enable a man to determine the best arrangement of his motive power and dynamos—which, after all, are the most important parts of the installation—and also with sufficient electrical knowledge to enable him to clearly determine the most efficient and substantial arrangement for the erection of the cables, lamps, &c.

Such a course as this not only places the purchaser in a position where he has the advantage of a man's experience and guidance, but the contractor knows exactly what he has to supply to comply with the specification; he also feels that he is dealing with a man of experience who is capable of deciding any question that may arise, and prevent disputes or differences on either side.

Whilst upon the subject of tenders for electric light installations I should like to say a few words about the way tenders are sent in to the purchasers.

I have in many cases tendered for installations, sending complete specifications, tenders, and drawings, whereas my competitors have simply tendered, without accurately stating what they intend to supply. For instance, on one occasion I was asked to tender for an installation, and the following specification was read out from a tender they had received:—"1 120-light dynamo, 1 main switch, 60 16 candle-power incandescent lamps, 60 lampholders, 60 factory pendants, 440 yards insulated cable for pit, 880 yards insulated cable above ground."

Now, anyone who understands the subject will see at a glance that any one of the items in the above means practically anything, as neither the speed of the dynamo, description of switch, kind of lampholders, what sort of pendant a factory pendant is, and lastly, but not least, what does insulated cable mean, is stated.

As this tender was given by a firm who have a good reputation, it probably was not so misleading as it might have been; but I took the opportunity of sending in two tenders, one in the style of my competitor, and one as I thought it should be done. Of course the two prices were very different.

In conclusion I can, for your satisfaction, state that my conclusions are not merely thoughts, but the convictions I have arrived at after actual experience, and I am sure that although my suggestions may not meet with the approval of some people, yet I feel satisfied that any firm who intend to do the work really well and conscientiously would much prefer working under an engineer to dealing with people who do not understand the work or what they want, and unfortunately sometimes think they do.—Yours, &c.,

W. C. MOUNTAIN.

For the Gülcher Electric Light and Power Company (Limited).

Battersea Foundry, S.W., June 20th, 1887.

THE NEWTON PRIMARY BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your kind notice of the "Newton Primary Battery" exhibited by us, we beg to point out that the statement to which you apparently take exception is fully justified by the facts of the case, for by the system alluded to the electric light can be supplied to consumers at a price not

Digitized by Google

higher than gas at 4s. 6d. per 1,000 cubic feet, which we maintain is a reasonable figure, seeing that 7s. 6d. is charged for gas in places not 100 miles from London.—Yours, &c.,

SAM. TUGMAN, Director,
The New Electric Light Syndicate.

2A, West-street, Finsbury, 23rd June, 1887.

THE VARIATION OF THE RESISTANCE OF FAULTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have, of course, read with much interest Mr. Kennelly's paper on the variation of the resistance of faults, and also Prof. Jamieson's letter on the subject in your number of May 6th. I am rather surprised, however, that Prof. Jamieson did not see that in the example he gives my formula correctly expresses the resistance of the cable up to the fault, according to Kenney's law. For,

Let x = the resistance up to the fault,
y = the resistance of the fault when tested with 40 cells.

Then, according to Kennelly's law, $\sqrt{4}\,y$ or $2y$ = the resistance of the fault when tested with 10 cells.

Prof. Jamieson has correctly given my formula for the resistance of the cable up to the fault as $\frac{n\,B - A}{n-1}$, where B is the resistance of the cable and fault when tested with the larger number of cells, and A the resistance of cable and fault when tested with the smaller number of cells, $2\ n$ to 1 being the ratio between the number of cells used in the two tests.

When the ratio is 4 to 1 this formula becomes simply $2\,B - A$, as Prof. Jamieson has shown—

Then $B = x + y$,
and $A = x + 2\,y$,
according to Kennelly's rule.

Therefore $2\,B - A = 2\,(x+y) - (x+2\,y) = x$ = the resistance of the cable to the fault, so that for this ratio of 1 to 4 my formula agrees with Kennelly's law, supposing that the currents passing through the fault vary with the number of cells used.

If we take n as the ratio between the cells used in the two tests my formula will be

$$x = \frac{\frac{n}{2}B - A}{\frac{n}{2} - 1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and the corresponding formula according to Kennelly's law will give

$$x = \frac{\sqrt{n}\,B - A}{\sqrt{n} - 1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

It will be seen at once that these formulæ agree when $n = 4$.

My formula was based on a large number of observations made many years ago. Within certain limits I found that the ratio of the resistances of the fault was one half the inverse ratio of the number of cells used. Thus, if the ratio of the cells were 1 to 4 the ratio of the resistance would be 2 to 1. If the ratio of the cells were 1 to 6 the ratio of the resistances would be 3 to 1, and so on, and the formula was founded on these observations. The measurements should always be taken with zinc to line; perhaps the neglect of this was the reason Prof. Jamieson's results were not altogether satisfactory.

As far as I remember the observations were made in 1873. I gave the formula to Mr. Cuff, of the Eastern Extension Telegraph Company, and the test was first used by him when the Singapore Hong Kong cable was broken, during a typhoon about 1874 or 1875, when the ratio test was the only one which gave the position of the break with anything like an approach to accuracy.

I did not publish the formula, partly because it is inapplicable to the ratio 1 to 2 in the number of cells, and I found on further experiment, I believe, that the alteration in the resistance was only apparent. I am, however, much obliged to Prof. Jamieson for referring to the formula.

I am not sure whether I still have a record of my numerical results, but they gave me what I required at the time, namely, a means of eliminating the resistance of the fault. I shall in any case repeat the observations now that the subject has been so ably brought forward by Mr. Kennelly, and endeavour to discover the reason for the difference between his results and mine.

According to my results we get formula (1) as follows:—

With current C we have

$$A = x + \frac{n}{2}y \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

With current $n\,c$ we have

$$B = x + y \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Then from (3) we get $y = \frac{2A - 2x}{n}$,

and from (4) $y = B - x$.

Equating these values of y we have

$$B - x = \frac{2A - 2x}{n},$$

from which we get

$$x = \frac{n\,B - 2\,A}{n-2} \text{ or } \frac{\frac{n}{2}B - A}{\frac{n}{2} - 1}$$

According to Kennelly's results we get formula (2) as follows:—

With current C we have

$$A = x \times \sqrt{n}\,y \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

With current $n\,c$ we have

$$B = x + y \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Then from (5) we get $y = \frac{A - x}{\sqrt{n}}$,

and from (6) $y = B - x$.

Equating these values of y we have

$$\frac{A - x}{\sqrt{n}} = B - x$$

From which we get $X = \frac{\sqrt{n}\,B - A}{\sqrt{n} - 1}$.

In each case the resistance of the fault is eliminated.—Yours, &c.,

G. K. WINTER, M.I.C.E., M.S.T.E.,
Telegraph Engineer Madras Railway.

Arkonam, 27th May, 1887.

SPECIFICATION.

SPECIFICATION FOR CERTAIN COMPONENT PARTS OF STANDARD IRON TELEGRAPH POSTS FOR THE GOVERNMENT OF INDIA.

[We think that many of our readers will be glad to read the specification for telegraph and other material issued by the India or other offices from time to time, and therefore we give the following specification relating to telegraph posts, tenders for which have to be sent in before 2 p.m. on Tuesday, June 28, 1887.—ED. *E.*]

1. All the component parts are to be of the best materials and workmanship, and to be made in accordance with the drawings and patterns, which may be seen on application to the superintendent of the India Store Depot, Belvedere-road, Lambeth, S.E.

2. *Sole Plates.*—The sole plates are to be made of the best grey metal, cleanly cast and blackened. To test the fitting of the screws, 1 per cent. of the sole plates shall be screwed on to the sockets. In the event of any misfit the whole may be screwed on. By misfit in this case is meant a sole plate not entering on the screw of the socket sufficiently to take $1\frac{1}{4}$ complete turns. The thickness of the corrugated web to be $\frac{3}{16}$ of an inch.

3. *Sockets.*—The sockets are to be made of the best grey metal, cleanly cast and blackened, and in order to ensure the concentricity of the cast-iron sockets, the contractors shall have the bearings of the core barrels and seatings of the moulding boxes, with which they are made, turned and bored respectively. Five per 1,000 of the rough castings will be broken at the expense of the contractor, to determine their accuracy in this respect.

4. *Caps.*—The caps are to be made of the best annealed malle-

Digitized by Google

able cast iron, and are to be well galvanised with pure zinc. The socket in the cap is to be rimered out and gauged for size. A manufacturing margin of $\frac{1}{16}$ of an inch, either upwards or downwards, will be allowed for the entrance of the gauge. A ring and plug gauge, corrected to the standard at the India Store Depot, will be supplied to the manufacturer on his tender being accepted, and is to be returned to the superintendent of the India Store Depot on the completion of the contract.

5. Each sole plate, socket, and cap is to have its distinguishing letter, the India Government mark, the letters T. D., the name of the contractor, and the year of manufacture cast on it, thus ;—

$$\begin{array}{c} \wedge \\ | \\ \mathrm{I} \\ \mathrm{B.} \quad \mathrm{T.\,D.} \quad \mathrm{Z.} \quad . \quad . \quad . \quad . \quad \& \mathrm{Co.} \\ 1887 \end{array}$$

in block letters and figures, which must be well defined.

6. *Tubes.*—The galvanised wrought-iron tubes are to be of B. B. S. iron, equal in quality to pattern No. $\frac{2845}{\mathrm{H}}$ at the India Store Depot. Samples of the iron proposed to be used are to be submitted for the approval of the superintendent of the India Store Depot before the manufacture of the tubes is commenced. The letter distinguishing the size of a tube is to be punched out of the metal of the outside hoop at the bottom of the tube before it is riveted on. The inner strengthening rings of the tubes are to be driven home hard, the drawings merely showing their normal position.

7. The rivets for the galvanised wrought-iron tubes must be of such a quality that they will stand riveting cold.

8. The wrought-iron tubes, inner strengthening rings, and outside hoops are to be well galvanised with pure zinc, before and after they are put together. The zinc is to be evenly deposited and free from spots.

9. The superintendent of the India Store Depot or his deputy may be present during the whole process of making the component parts specified in the schedule, and they shall have every facility for seeing them during all stages of their manufacture ; but samples of the finished work are to be forwarded for approval, free of expense, to the superintendent of the India Store Depot, from time to time, as he may direct.

10. To ensure that all the component parts fit, there is in the drawings a dotted line called the "fitting line." When the posts are taken for testing purposes, the superintendent of the India Store Depot, or his deputy, will choose at random the component parts to be fitted together. On their being so fitted, should they find that any one component part in the total quantity either does not reach, or passes, this "fitting line" by more than 2in., they shall gauge one per 1,000 ; if they find another misfit they shall gauge 10 per 1,000, and a third out of gauge will cause the whole quantity to be gauged. In such cases the portions to be gauged are the outer upper diameters of the sockets, and the inner lower and the outer upper diameters of each tube, except tube A, which must be gauged for inside diameters at both ends.

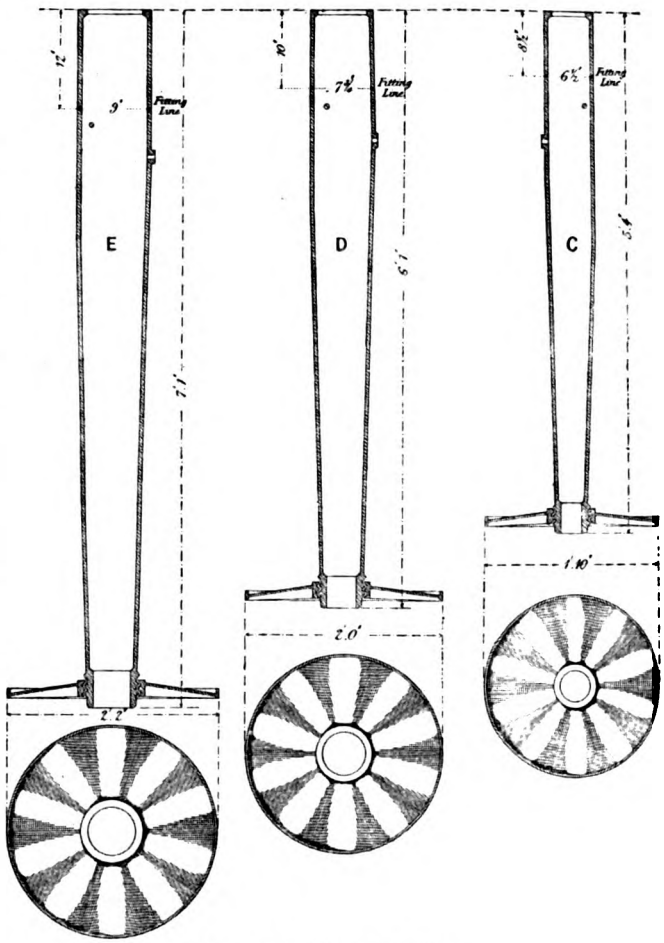
11. The following table gives the minimum breaking weight and minimum weight at which each size of a complete post of two galvanised tubes and a socket may take a permanent set of a curve with a versed sine of half an inch :—

Size.			Breaking weight.	Weight for working load and permanent set of not more than $\frac{1}{2}$in.
Tube.		Socket.	Lbs.	Lbs.
A, Z	with	Z	400	274
A, B	,,	B	500	344
B, C	,,	C	840	576
C, D	,,	D	1,500	1,033
D, E	,,	D	2,400	1,650

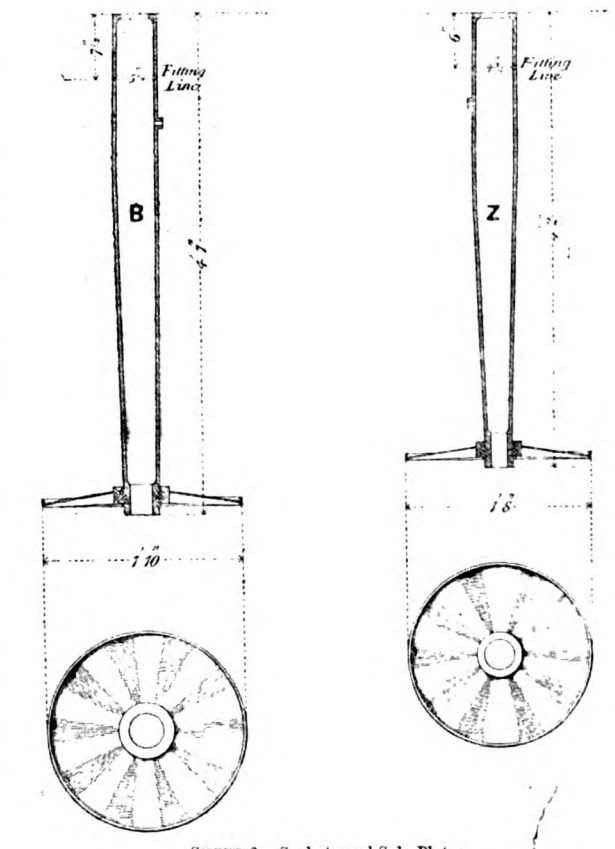
These are the actual pulls or dead loads at the line of wires when the posts are in working order or vertical, but, as the whole are to be tested horizontally, two-fifths of the average weight of the two tubes, taken in even pounds, is to be deducted for the overhanging weight of the post itself.

12. The component parts being ordered singly, the tests for minimum breaking strength, and also for working strength and permanent set, are to be determined exactly according to the foregoing table, and, where needed, the necessary lengths to make out the full length shall be furnished for purposes of testing by the contractor. The strength of the A 5ft., and of the Z tubes, shall in all cases be at least equal to that specified for the B, C posts, both for the minimum breaking strain and also for the working strain giving the permanent set.

13. One per 1,000 of the galvanised tubes will be tested up to destruction. Should they not all give the required test, one per 100 must be tested to the minimum breaking strain ; if, then, one per 100 should break at less than the minimum breaking strain, 10 per cent. of the quantity submitted for examination must be tested to the minimum breaking strain, and, if it be found from this that more than one per cent. has broken at less than the minimum breaking strain, the whole must be absolutely rejected.



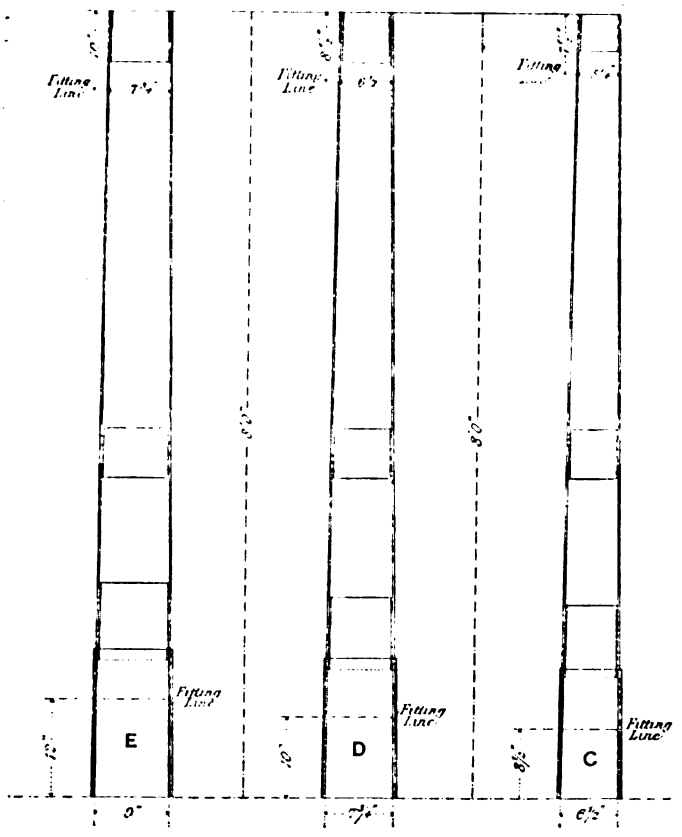
SHEET 1.—Sockets and Sole Plates.



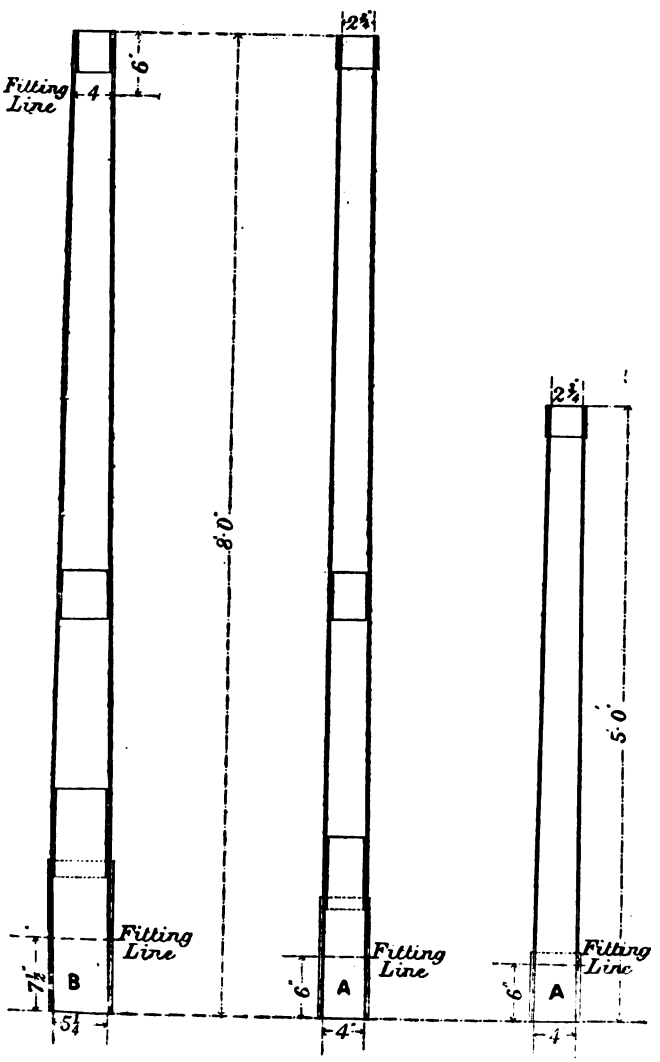
SHEET 2.—Sockets and Sole Plates

14. The tests will be conducted as follows :—The tubes and sockets to be tested shall be fitted together, and the whole laid

Digitized by Google



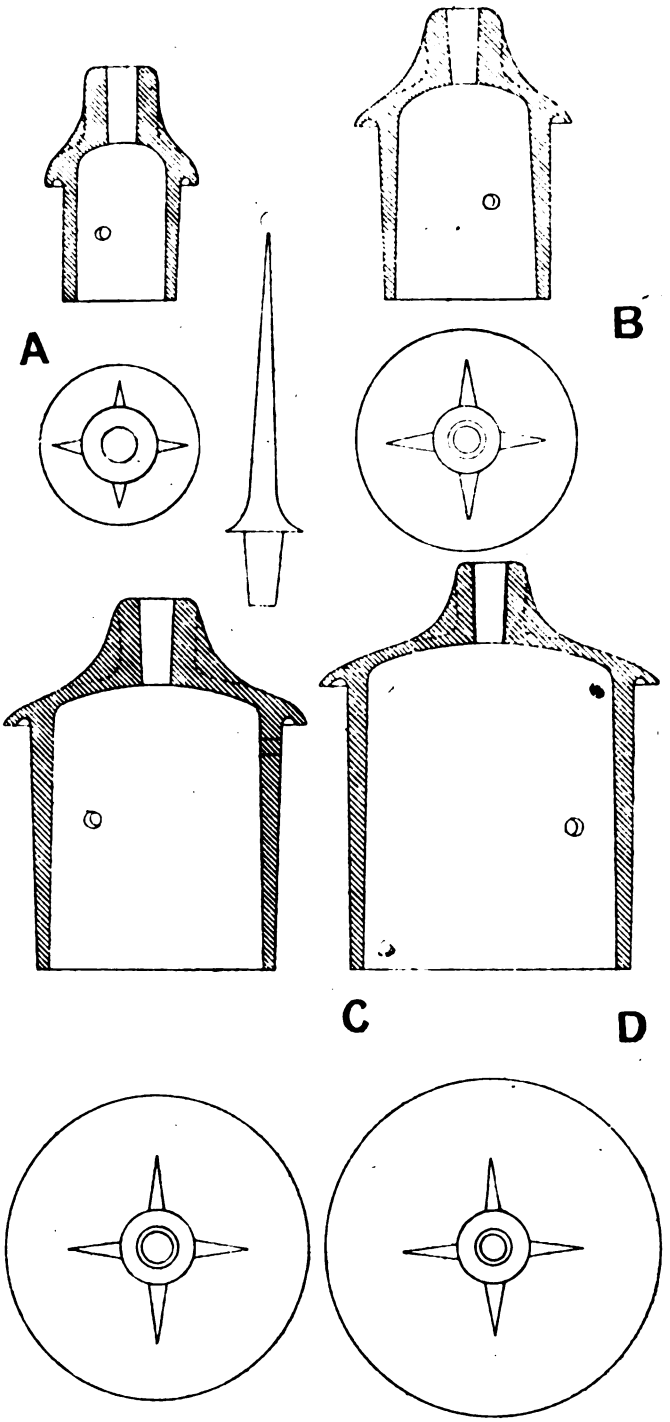
SHEET 3.—Galvanised Tubes.



SHEET 4.—Galvanised Tubes.

horizontally, so that the total weight shall rest upon a support at the ground line of the socket, viz., 1ft. from the bottom of the lower galvanised wrought-iron tube, and no part of the support is to be brought nearer the bottom of the lower tube than 1ft., a shackle or strap holding down the socket at the bottom end, the post being thus supported on its working fulcrum. The test load shall then be hung on at the line of brackets, or 1ft. from the top end of the post.

15. In testing for permanent set, the tubes and sockets shall be fixed in the same way as described above, and the working or dead permanent set test load, as shown in the above table, shall be hung on the post at the line of brackets, or 1ft. from the top end, and with



SHEET 5.—Galvanised Caps and Lightning Discharger.

this load the permanent set, measured as a versed sine from a chord stretched from the bottom to the top of the galvanised wrought-iron portion of the post, after the weight is removed, shall not exceed half an inch.

16. The testing shall be performed by the Superintendent of the India Store Depot, or his deputy, for which purpose the contractor must supply all necessary machinery, apparatus, a complete set of gauges and templates, convenience, labour, and assistance of every kind required for the purpose, without making any claim or charge for the same, it being distinctly understood that these expenses are included in the prices stated in the tender. All tubes or sockets

Digitized by Google

broken or otherwise destroyed in testing, and any additional lengths required, as mentioned in paragraph 12, are to be at the expense of the contractor. All testing apparatus, &c., is to be under the control of the Superintendent of the India Store Depot, or his deputy, during the period of examination.

17. The galvanised caps are to be packed in cases made of 1in. (full) deal, with two battens each top and bottom, and to be bound with 1in. hoop iron. Each case is to contain 25 of the A size. The packing is to be done to the entire satisfaction of the superintendent of the India Store Depot or his deputy. Instructions for marking the cases will be forwarded by the superintendent of the India Store Depot when the stores have been approved. Should any damage be discovered on the arrival of the stores in India which may be attributable in any way to defective packing, the contractor will be held responsible for any loss that may arise therefrom.

18. Proper accommodation, under the control of the superintendent of the India Store Depot or his deputy, is to be provided by the contractor for the storage of approved and the distinct and safe custody of rejected stores until finally disposed of.

SCHEDULE.

D. O. 5539,

Home, No. 174. Bombay and Madras. 16 Telegraph.

Telegraph Indent, No. 27, of 2nd May, 1887.

Standard Iron Telegraph Posts, Component Parts	Pattern Number at India Store Depot.	Quantity required.			Weight of each part.
		For Bombay.	For Madras.	Total.	
	For make	No.	No.	No.	Cwt. qr. lb. oz.
Caps, A	A, 1884	—	500	500	0 0 2 6

,, ,, C ...	C ,,	—	4,100	4,100	0 1 4 0

To be supplied in accordance with the annexed specification.

N.B.—The tender should state the earliest date by which the contract could be completed.

[Five sheets of drawings accompany the specification. These drawings have been reduced, and are given herewith.—ED. *E.*]

THE ELECTRO-DEPOSITION OF IRON.

BY PROF. W. CHANDLER ROBERTS-AUSTIN, F.R.S.

The great interest which would attend the investigation of the properties of pure iron has long been recognised, and although but few results have as yet been obtained, elaborate preparations for such an inquiry have from time to time been made. A committee appointed by the British Association described in 1869 a method which yielded iron of a high degree of purity, the work being entrusted to the late Prof. Matthiessen, who ignited pure ferrous sulphate mixed with sodium sulphate, reduced to oxide of iron, so obtained by pure hydrogen, and melted the spongy iron in a lime crucible before the oxy-hydrogen blow-pipe. The committee reported "that, with regard to the physical properties of pure iron, owing to the want of time, nothing has as yet been accurately determined." It appears, however, that many of the physical properties of the pure metal differ considerably from those of the commercial. The work appears to have been interrupted by Matthiessen's lamented death, which occurred in the following year. It may be that metallurgists have been satisfied that Bessemer metal is sufficiently pure to afford a basis for investigation without resorting to elaborate chemical methods of preparation, for but little has hitherto been done to prepare on a large scale a material in which the above-mentioned impurities are entirely absent. The volume of the reports of the British Association, to which reference has just been made, also embodies a paper by M. H. Jacobi, of St. Petersburg, whose name is so well known in connection with electro-metallurgy. M. H. Jacobi and M. Eugène Klein took out a patent in this country in 1869 (No. 2,456), which was, however, allowed to lapse. Jacobi worked for some days in the mint laboratory, and communicated to me the details of the methods of manipulation, and in 1870 I visited St. Petersburg, and had the advantage of seeing the iron deposited on a large scale with a view to the preparation of plates to be used for printing the paper money of Russia.

The deposition of iron is attended with many difficulties, and in this country, so far as I know, iron has only been deposited electrolytically on a very small scale, and the metal deposited has been considered rather a metallurgical curiosity than as possessing any practical value. It may be well to describe briefly the method of procedure. "The bath used is a solution of ferrous sulphate and magnesium sulphate in equivalent proportions of specific gravity 1·155. The solution must be so far neutralised by the addition of magnesium carbonate that blue litmus paper barely shows any acid reaction. A wrought-iron anode of about the same size as the object which is to receive the deposit must be employed, and the best interval between the poles proved to be 4 c.m. The secret of success appears to be in the use of very feeble currents. Mr. W. H. Preece, F.R.S., electrician to the Post Office, has kindly afforded me facilities for determining the strength of the currents employed, and it may be sufficient to state that the current best suited for the deposition of an iron medallion, the surface of which measured 560 sq. c.m., proved to have a strength of only 0·089 ampere, and such a current was yielded by two Smee's cells, each having a silver plate of 50 sq. c.m. area coupled up for intensity. The only objection to the process is the length of time required for its completion. It was not found possible to deposit such a medallion of sufficient thickness for use in the reducing machine in less than three weeks. The adherence of the deposited iron to the surface of the copper gives rise to considerable difficulty in detaching it, and in order to reduce this adherence it was found best to throw down on the copper model a thin film of nickel, and after exposing this for a short time to the air in order to slightly tarnish its surface to cover it with a second film of nickel, on which the iron was subsequently deposited. Even when this precaution was taken several moulds were spoilt by partial adherence of the iron and copper through the nickel. I am now conducting some experiments on the deposition of iron on copper moulds covered with a thin layer of silver iodide, that substance being well known as an excellent conductor." The metal has a high degree of purity. Mr. A. Dingham, a skilful analyst in my laboratory at the Royal School of Mines, finds that a specimen submitted to certain physical tests, to which reference will be made presently, contained only the slightest trace of magnesium and 0·005 per cent. of sulphur. Its density is 7·675, which becomes 7·811 when the metal is annealed. By annealing carefully-measured strips of metal they were found to contract about 1 per cent. of their length. I found in 1869 that the metal as deposited occludes from 17 to 20 times its volume of hydrogen. Cailletet showed that iron deposited under certain conditions occludes 248 times its volume of hydrogen, the pressure of which gas renders the metal very hard, and augments considerably its coercive force when magnetised. Notwithstanding the purity of the metal its magnetic capacity does not appear to be high. Tested by the magnetic balance designed by Prof. Hughes, it would appear to possess less than two-thirds the magnetic capacity of a strip of Russian sheet of the same dimensions. The magnetic capacity of the strip of electro-iron rises considerably when the metal is annealed, which tends to show that the defective magnetic quality is due to the aggregation of the metal, and not to impurity, as well as to the partial expulsion of the occluded gas. With a view, however, to set this important question of magnetic influence at rest, I have deposited a carefully-turned rod of copper, 1·01 foot in length, 0·511 inch in diameter, and of a maximum thickness of 0·035 inch. Dr. John Hopkinson having expressed a wish to conduct some experiments in this direction, the rod (now exhibited) will be placed in his hands.

From the point of view of its molecular structure the electro-deposited iron promises to afford interesting experimental results. Strips of the iron about 5·4 inches in length, 0·033 inch in thickness, and 0·75 inch in breadth, were tested for tensile strength. It was found that the deposited metal crushed in the jaws of the machine, and it was therefore necessary to anneal the ends of the test piece before submitting it to stress. A piece of deposited iron so treated broke in the centre of the strip with a load of 2·7 tons per square inch. A similar strip annealed at the temperature of molten zinc (about 412° C.) was found to possess a tensile strength of 13½ tons per square inch, and another piece annealed at a temperature between the melting point of silver (940° C.) and that of the melting point of aluminium (about 300° C.) had a tenacity of 15½ tons per square inch, two separate experiments agreeing very closely. The elongation was in each cast very small, and very delicate instruments would be required to determine its amount with accuracy. It will thus in future experiments be possible to examine by photographic methods, described by Mr. Sorby, the change in structure of a pure, brittle, and non-coherent metal to one having a considerable tenacity.

The use of electro-deposited iron for printing purposes has already been mentioned. One other application remains to be described.

Many years ago I suggested that electro-deposits of iron should be employed with a view to test the capabilities of a machine devised for reducing designs modelled in low relief, and the reproductions in metal and ivory were so faithful that the superiority of such iron deposits to the metal casts or copper electrotype ordinarily employed was at once demonstrated.

Digitized by Google

The preparation of the dies for the coins to be struck on the occasion of the Jubilee of Her Majesty the Queen presented a favourable opportunity for the more extended application of similar deposits of iron. The designs modelled in plaster were reproduced in "intaglio" by the electrolytic deposition of copper, and on the copper moulds so prepared iron was deposited. The iron proved to be hard and of excellent quality, and up to the date of this paper obverse dies of all denominations of gold and silver coin, as well as the obverse of a medal, have been produced by a reducing machine from such deposits.

If they were to take a plate of copper and deposit on it a layer of iron, then glue to the back of the iron a piece of wood, and wrest the iron away from the copper, the iron did not separate cleanly, but the iron slipped off copper, just as it was asserted that a bank-note could be split by glueing it between two surfaces of wood. What this meant he did not at present know, but it was a question that he was investigating. The paper was by no means in a state in which he could have wished to present it to the Institute; but he thought that the interest attached to the exhibition for the first time in London of a medallion, and that medallion in iron, and a portrait of Her Majesty, was likely to be of far more interest to the members of the Institution than any remarks he could have to offer in the interval between now and the next meeting.

THE MEASUREMENT OF SELF-INDUCTION, MUTUAL INDUCTION, AND CAPACITY.

BY W. E. SUMPNER, B.SC.

(Continued from page 128.)

Fig. 3 represents a method of comparing two capacities. We may regard the branch s as having an effective self-induction of

$$\frac{r}{p} \cdot q^2 K_q - s^2 K_s$$

Fig. 4 represents a method of comparing mutual induction with capacity. We may regard the effective self-induction of the branch r as being

$$\pm\frac{s+q}{q} M_{rb} - qr K$$

Fig. 5 represents Maxwell's method of comparing self-induction with capacity. We may regard the effective self-induction of the branch r as being

$$L_r - qr K_q.$$

Fig. 6 represents Maxwell's method of comparing self-induction with mutual induction. The effective self-induction of the branch s is

$$L_s \pm \frac{p+r}{p} M_{sb}.$$

Figs. 7, 8, 9 represent analogous methods of finding self-induction, mutual induction, and capacity. The effective self-induction of the branch s is L_s for Fig. 7, $\frac{p+r}{p} M_{sb}$ for Fig. 8, and $-s^2 K_s$ for Fig. 9.

Fig. 10 is an illustration of the combination of the above methods. The effective self-induction of the branch s in this case is

$$L_s - ps K_p \pm \frac{s+q}{q} \cdot \frac{q}{p} M_{rb} - \frac{q}{p} L_r.$$

The interest of the above methods consists in the fact that they are methods to measure absolutely the difference between two quantities. The most accurate way of measuring the ratio of two resistances is well known to be that of Prof. Carey Foster, who measures the difference between two nearly equal resistances in terms of the resistance of an observed length of a uniform wire; and by that means, if either of the resistances is known fairly accurately, their ratio can be determined with extreme accuracy. The above methods are analogous with that of Prof. Carey Foster.

When, however, we employ the cumulative method exemplified in the secohmmeter of Profs. Ayrton and Perry, the analogy is still more complete. In using a wire bridge it is very difficult to determine the exact position of the slider, although it is very easy to determine accurately the difference between two of its positions; and the great accuracy of Prof. Foster's method is due to the fact that it is not necessary to determine the absolute position of the slider, because all that is required is the difference between two positions. Now, one of the faults of Maxwell's methods consists in the necessity of having a very exact balance of the bridge. As an example, when the branches r and s were each about 6,000 ohms, it was found necessary to adjust r to a small fraction of an ohm by adjusting the length of a bare wire connecting two terminals, and even then the heating caused by keeping on the battery for a moment so altered the balance that a correction had to be applied. However, when the cumulative method of Profs. Ayrton and Perry is employed, it is not necessary to have the bridge balanced at all. It is only necessary to have the bridge so nearly balanced that the spot may be on the scale.

This result is a simple deduction from equation (13) of the paper of Profs. Ayrton and Perry. It may also be proved as follows:—If there is no induction in the bridge, but the arm s is deranged from balance by an amount σ_0, the deflection D_0 of the galvanometer will be proportional to σ_0 for small derangements; so that

$$D_0 = k\sigma_0,$$

k being a constant. If the battery is on for only a portion (l) of the time, the deflection D_0^1 will be l times this; so that

$$D_0^1 = (l D_0) = lk\sigma_0;$$

and if we increase the branches r and s by small amounts proportional to r and s the deflection will not be altered. Now, in testing for self-induction we practically increase the resistance of the arm s by an amount σ in consequence of the self induction, and in order to find out what is the value of σ we increase the arm r by an amount which bears the same proportion to p that σ does to q. We shall know this is the case when the deflection of the galvanometer is $l D_0$, where l is the lead of the secohmmeter, *i.e.*, the proportion of the time the galvanometer and battery are on together to the period of the commutator. So that, in testing with the secohmmeter,

(1) Observe the position of rest (Z) of the spot.

(2) Adjust the bridge roughly for resistance until the spot comes to a point, D_0, not far from Z.

(3) Take a point on the scale between these two, such that its distance from Z bears to the distance between Z and D_0 the proportion of the lead of the instrument, and use this point as a zero.

(4) Derange the bridge by a known amount, and turn the secohmmeter till the spot of light passes slowly through the zero. At this moment press the key and take the speed reading.

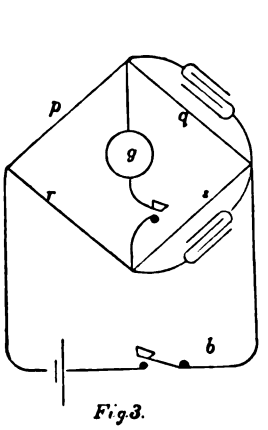

Fig. 3.

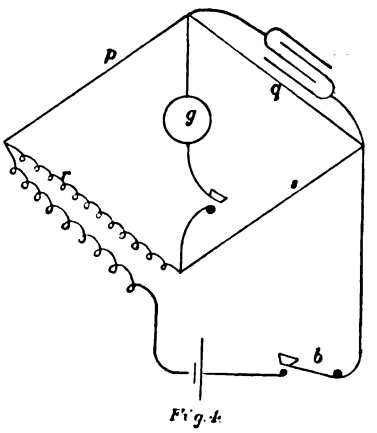

Fig. 4.

By this method only one error of judgment can arise, viz., the determination of the speed.

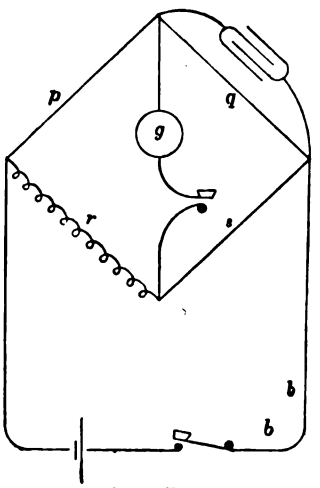

Fig. 5.

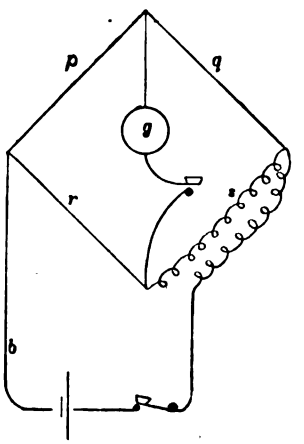

Fig. 6.

The analogy with the method of Prof. Foster is clearly shown by the fact that the same wire bridge can be used. If, as in Fig. 7, the resistance $p+q$ be that of a straight uniform wire, we have—

1. For resistance balance—

$$s : r = q : p,$$

or

$$s : r+s = q : q+p.$$

2. For commutative balance—

$$s+\sigma : r+s+\sigma = q' : q'+p',$$

where σ is the effective increase of resistance owing to self-induction.

$$\sigma = \frac{n L_s}{l},$$

n being the number of revolutions per second, and l the lead. q' is the new value of q', and $q'+p' = q+p$.

Now, generally, σ is small compared with s; so that

$$\sigma : r+s = q' - q : p+q,$$

and

$$L_s = \frac{l}{n}(q'-q)\frac{r+s}{p+q}.$$

The two chief advantages of the cumulative method are—

(1) Impulses are turned into steady currents as far as galvanometers are concerned, and therefore null methods are applicable which would otherwise be impossible.

(2) The sensibility of the galvanometer is practically multipled by the speed of the commutator. The only limit is that given by the ratio

Digitized by Google

between the period of the commutator and the time constant of the network, *i.e.*, the time needed for currents to completely establish themselves.

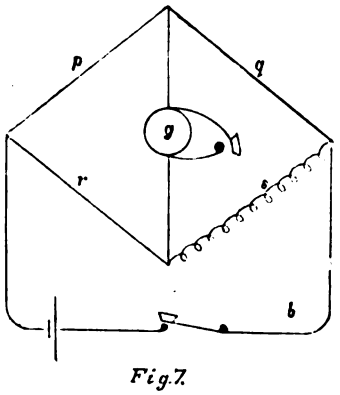

Fig. 7.

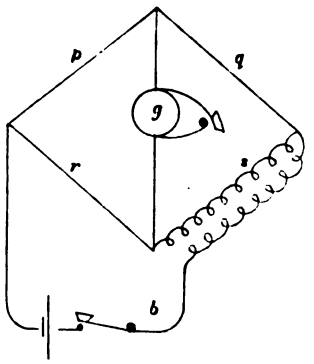

Fig. 8.

This renders it possible to much improve any existing null method, however good.

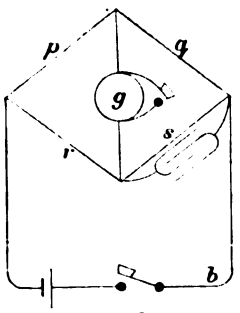

Fig 9.

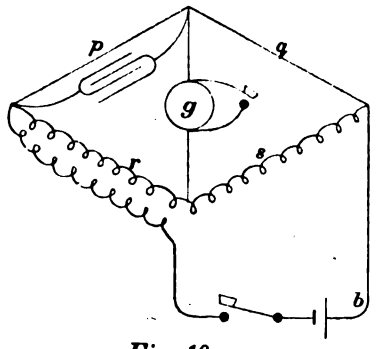

Fig 10.

The sensitiveness of any of the above-mentioned difference methods depends upon three considerations—

(1) The sensitiveness of the arrangement of the bridge for the measurement of resistance.

(2) The time constant of the bridge.

(3) The amount of the difference measured.

Thus, in order to determine the ratio between L and M accurately by the method of Fig. 6, it is necessary to remember that

$$L - a\,M = b\,D + \frac{\sigma}{N},$$

where D is the deflection caused by a small derangement from the null position, and a and b are constants; N is the speed reading of the secohmmeter, and σ the apparent increase of resistance. The most advantageous value of b will be given by (1) and (2), combined with the consideration that, other things being equal, it is best to have a as nearly equal to L/M as possible.

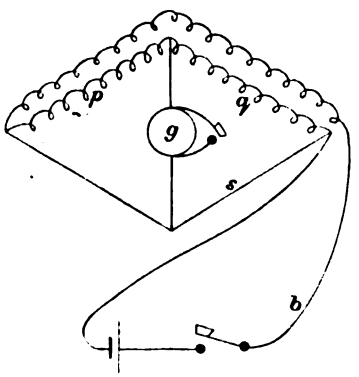

Fig 11.

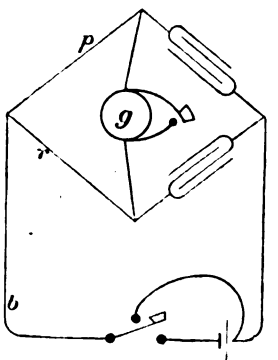

Fig 12.

If the comparative methods of Maxwell can be rendered delicate by cumulation, all that is required for practical purposes is done, for we have good standards of capacity, and coils of wire having constant self-induction can easily be made. If, however, the effects are not accumulated, it seems as though no comparative null method of measuring these quantities can be more delicate than would be the measurement of resistance by a Wheatstone bridge, if it were only possible to touch the battery key for an instant. This process is employed when the bridge is far from balance in order to prevent the effect on the galvanometer from being too great, and this is the process which must be used in the measurement of induction and capacity, since their effect vanishes after the first instant. Even the comparative method of Prof. Carey Foster, excellent as it is, could be much improved by using a cumulative method, not only because the galvanometer is rendered more sensitive, but also because a slight difficulty which renders a very exact balance impossible could be overcome—viz. unless the galvanometer is very ballistic, the condenser effect asserts itself before the mutual induction effect and produces a slight "kick" on the galvanometer, which it is difficult to allow for accurately.

If the cumulative method be employed, and the readings for different speeds plotted, the points should lie on a straight line. As the zero point on this line is absolutely known, it is possible to get the slope of the line with very great accuracy.

(*To be continued.*)

CENTRAL STATION CONSTRUCTION.*

BY J. A. POWERS.

There are two ways of constructing a central station for electric lighting each of which has its special object. They may be defined as the speculative and the investment plans. The first has as its legitimate, or, rather, its illegitimate end, the sale of the plant to some unfortunate, perhaps unwilling, capitalist, by fair means or foul. We may consider as fair means the not uncommon method of selling a small portion of the stock, perhaps just enough to pay for the apparatus, on the strength of a showy exhibition in the hands of an expert, who uses all the tricks of the trade to persuade his lambs that his system will produce double the light with half the power of any other, and the other customary arguments.

The foul means is the border ruffian money-or-your-life policy, which enters a territory already sufficiently well served, not for fair competition, but to make money by being bought out.

The electric light business is rapidly emerging from the border ruffian and blackmailing stage, and, as we may shortly expect these methods to be relegated to their proper realm with other things dead and dishonourable, with the growth of popular knowledge of electrical matters, we will leave them, and proceed to the more legitimate methods, which I hope you will all pursue.

"The fool doth think he is wise, but the wise man knows himself to be a fool," said the master of all writers, and that I may be saved entering the first class in your presence, I here confess to many and grievous mistakes in our own central station construction, to which this paper owes its being, for that I may hope to save some of you part of my errors is my only excuse for appearing before you.

Let us, then, drop speculation as a thing of the past in our business, and make our object the construction of such work as shall produce, in the sober judgment of every business man among you, the best results in economy of labour, supplies and power, with the least expenditure for interest, taxes, insurance and repairs.

In all manufacturing enterprises of the day one tendency is unmistakably felt. It is the direction of thorough work. To succeed in any established business one must have substantial buildings, the best improved machinery, the best site for obtaining necessary supplies at their cheapest. Electric lighting to-day has risen from the slough of speculation and stands side by side with other great manufacturing enterprises in importance. Not less than sixty million of dollars are invested in lighting plants alone, and in the entire field probably not less than double that sum. Has not the time come when the same laws of strict economy which obtain in other large enterprises should govern central station construction?

Let us carefully consider our problem, plan cautiously, and expend liberally in the directions which indicate the best results. It is evident, however, that we should not expend without limit. Where shall we draw the line? I believe we are safe in expending every dollar which is sure of saving 10 per cent. interest on its investment, provided we have it to spend. The only danger in the path seems to be the chance of such improvements as shall throw aside our present method of producing electricity. Let us for a moment consider the possibilities in this direction. The best dynamos will to day, in ordinary practice, convert 80 to 85 per cent of the power furnished them into an equivalent of electricity. Clearly there can be but small improvement here. Coal or similar fuel is the common source of power to-day, and seems likely to remain so. The best steam plants give one horse-power hour for about 1½lb. of coal. The actual energy stored in that 1½lb. of coal would give about seven horse-power hours if it could be converted into power without loss; or, in other words, the best steam plants of to day have an efficiency of about 13 per cent.

Prof. Houston remarked at the last convention of the National Electric Light Association that the field where lies the greatest chance for improvement is in the direction of thermo-electricity, the conversion of heat into electricity without the intervention of power. This is most certainly so; for if a process can be discovered which will have a reasonable efficiency, say 25 per cent, electric motors must soon supersede steam engines for power. The nature of the losses connected with the conversion of heat into other forms of energy does not, however, give much encouragement in this direction. The nature of such losses is in the diffusion of heat by conduction and radiation, which has always proved most difficult of control. If a process of simple conversion, without the attendant development of heat, can be devised, the chances of a good efficiency would be much improved, but where heat exists there is radiation, and where radiation is there will be serious loss. How serious we can only judge from our experience with the steam and other heat engines. It is probable that we are safe in investments in our expensive steam plants, at least to the extent of the life of these plants. Let us then return to our subject proper. The first matter of importance to be decided in establishing an electric light station is its location. The necessary qualifications for location may be classed about as follows:—

* Paper read before the American Institute of Electrical Engineers, May 18th, 1887.

Digitized by Google

1st. A dry soil—a gravelly soil which will easily leach away the runnings from small drips or leaks, is preferable, next to solid rock. If located near a river, a wide margin of safety from flood should be allowed.

2nd. If practicable, a location near a plentiful water supply should be chosen. Condensation of either high or low pressure engines is desirable in every way, and requires a large water supply.

3rd. Nearness to the coal supply. If possible, locate near a navigable stream, so as to secure cheapness of handling coal and a plentiful supply of water. If not near navigable water, get a location on a railroad switch, and, if possible, near the water supply. If the two conditions cannot be fulfilled, you may make your choice between them, remembering that each additional handling of coal will cost about 10 cents per ton, and extra haul about 10 cents per 1,000ft., and, on the other hand, that condensing your engines will probably save between 15 per cent. and 25 per cent. of your coal expense. The pressing necessity for locating near the lighting field has largely passed away with the introduction of long-distance systems of incandescent lighting.

Having determined on a location, the character of building to be erected must next be considered. The most important single condition essential to the success of the electric light business is continuous and reliable service to customers. The most disastrous calamity which can befall an electric lighting business is the destruction of its central station. The first thing necessary to prevent such a calamity is a building practically fireproof, and I believe a brick building best fulfils these conditions. Let the walls be bare, make all floors double planked and supported on iron beams, use no wood ceiling, however seductive it may be in improving the appearance of your station; leave as few openings as possible through the floors; have a nearly flat roof with fire walls projecting above, and the building will be as nearly fireproof as it can be, and at the same time fulfil the other essential conditions of insulation, and a reasonable expenditure of capital. Before leaving the matter of fire protection, let me strongly advocate the use of some good automatic sprinkler, except in the dynamo room, and especially in parts of the building unoccupied during portions of the day. A stand pipe connected with your spare pump with nozzles on each floor, a few lengths of mill hose, a cask or two set in convenient places and kept filled with water and a few fire pails near are cheaply provided, and the improvement in insurance rates will soon pay for them. At Troy the reduction of rates has paid for the entire fire outfit in the saving in one year's premiums.

Before we design our station further, let me remark that the old adage that "cleanliness is next to godliness" would be a most wholesome motto for the electric light business. Dirt begets dirt, and with electrical apparatus it is by far the most fruitful source of short circuits, grounds, and consequently of burned armatures and disordered apparatus generally. Let us, then, so arrange our station that that most fruitful source of dirt, our boiler house, may give as little trouble as possible. Putting the boilers in the cellar and the engines and dynamos on the floor above is probably the worst possible arrangement next to putting all in the same room, since every opening in the floor conveys a blast of hot air, laden with coal dust and ashes. The correct method is to separate boiler and engine rooms by a fire wall and make the only opening between through a room or passage through which a strong draft of air is always passing. This we effect at Troy by means of an air shaft 6ft. by 8ft., which also serves as a wire tower, and in which wash sinks, &c., are also constructed. The doors leading in both directions are kept shut by heavy springs, and when opened the strong draft carries all dust, smells, &c., up the chimney. This shaft is carried above the roof and the wires are carried out between the louvres of the blinds. One thing do not forget. Arrange a cellar or basement under your dynamo and engine room floor about six feet deep. You will find it infinitely convenient in connecting small pipes, &c., to the under side of the floor.

Make your dynamo room not less than ten feet high for the comfort of your men, and arrange the windows to open clear up to the ceiling, as that is where the hot air will go to escape. You may also put your windows six feet above the floor, and you will save annoyance from spectators and your men will not have so much looking to do.

The boiler house should be light in construction, having an iron roof with some outside covering, such as asphalte, to prevent sweating in cold weather. The boiler fronts should, of course, face either on an open lot or a street to facilitate handling boilers, and for the same reason the front of the boiler house should be easily removable. The floor should be of concrete not less than a foot in thickness, made of the best Portland cement, mixed about one part cement, three parts sharp sand, three parts stone, broken to pass 1½in. ring. On this may be laid a floor of flags or arch brick laid on edge. No floor of cement or of ordinary brick will stand wear.

Going back to our main building, I will follow more particularly the line of work adopted at Troy. Our lot measures 50ft. by 13.ft, and the problem was to develop on that space a station of a maximum capacity of 500 horse-power effective. The lot was occupied by a mere shed covering two 80 horse-power boilers located almost exactly in the middle of the lot; one 150 horse-power compound engine just beside the boiler, belted to 48ft. of jack shaft lying parallel with the length of lot, and 2ft. 6in. above the floor, the dynamos lying each side of the shaft, the pull of the belts being nearly balanced.

The new station was laid out in a dynamo room 50 by 90, and boiler house 40 by 50ft., arranged for a battery of four boilers 72in. by 17ft., stack 13ft. square at ground, and 125ft. above the grates; wire tower in corner between dynamo room and boiler house projecting into the latter. As originally laid out, the engine stood in the new dynamo room close beside the fire wall now separating engine and boiler rooms, and the boilers further out in the dynamo room. It was decided to build the unoccupied end of the dynamo room, put in engine power connected with the old boiler, shift the station, abandon the old engine temporarily, build the rest of the new station over the old, put in new boilers, then connect them and disconnect the old boilers, remove the old boilers, and finish the inside of the building. The company changed hands on May 23, 1885, and on September 1st the old station was shut down at midnight, and the dynamos shifted to the finished part of the new building, and at six the following evening the station was in full operation in its new quarters. The plant then comprised about 600 Weston incandescent lights and some 20 arc lights. The remainder of the work was merely a question of time, and the station was first operated on its new boilers on December 17, 1885. At the same time about fifteen miles of pole lines were constructed, and some thirty miles of wire strung for the city contract of 130 lights.

The general construction of the Troy station is believed to cover the average conditions met with in central station construction, and is therefore particularised. In the arrangement of dynamos and engines we desired to attain the best economical results in the following items:

1st. Best average economy in coal.
2nd. Best average economy in transmission of power to its work.
3rd. Best economy of attendance.
4th. Best economy of oil, waste, &c. Our customers required a day service, and we had to take this into account in our selection of engines for power, and in their arrangement.

These conditions were to be borne in mind in the selection of our engines, and, in addition, the most important condition of reliability. Compound engines offered us the best coal economy, with maximum load, but had the disadvantage of poor economy with light loads. Corliss engines would occupy too much room, and both required shafting and counters to speed up, and would have forced us to use the second floor for dynamos, with the attending disadvantages of extra help and upright belting. We finally decided on using the best type of high speed engines, and purchased three engines of 9 by 14 cylinder, each belted to a jack-shaft 16ft. long, and each driving four 110-light incandescent dynamos, belted in pairs from opposite sides of the shaft. The lengths were arranged to be coupled by friction clutches. This arrangement gave us a very uniform rate of coal economy, though not a very high one. The arrangement of belting made the shaft friction very small. The old compound was set to work on its proper duty of driving a fixed load of city lights.

The relative merits of compound Corliss or high-speed engines are well understood, and the circumstances must in every case decide the type of engine proper to be used.

Where the maximum of output is required from a small space high speed becomes a necessity. Where the load is very variable a number of smaller engines will give as good average coal economy as a single larger engine, with less chance of a complete failure. Where the load is heavy and constant, a pair of large engines will give the best economical results and at the same time cover the possibility of a complete breakdown. The new triple expansion engines, which are rapidly replacing all others in ocean and lake steamers on account of their wonderful coal economy, will probably displace all others in the field.

Condensing high speed engines have not met with much favour, but we find at Troy that our "straight-line" engines work quite as quietly under 28 inches vacuum as without, and that the coal economy is considerably improved, probably from 15 to 20 per cent. on the engines condensed. They have also the advantage of giving us much more power for cases of emergency.

As to boilers, I am strongly in favour of boilers of large size; ours measure 60in. × 17ft., and are of Nashua "Indian head" steel, 7-16th shell, ½in. head, and have 136 3in. tubes. The dimensions of the tubes 3in. × 17ft. would be out of all proportions for ordinary drafts, but our stack 125ft. above the grates gives us ample draft, and the small tubes a great evaporating surface, and consequently a better evaporation. I am afraid I shall be considered a little unsound of mind when I state that with these boilers we are able, and do, evaporate with a mixture of one part bituminous to two of yard pea and dust nine pounds of water per pound of coal, and with ordinary buckwheat coal ten pounds of coal, feed water at 200 degrees. But such is the case, as I shall be happy to show any one visiting us. This is not pounds of combustible, but of coal. I have always found the ashes to cost just as much per ton as the fuel part of the coal, and therefore consider that they have no place in the relation of evaporation per dollar. We keep a daily and nightly record of our evaporation by a Worthington meter, which is on the boiler feed, and let me say that the bad reputation for veracity of meters in general will not apply to our meter, as repeated tests show a nearly constant error of 2 per cent. low.

For boiler feeds provide a reliable injector in addition to feed pump, which latter should always be used in connection with a good heater. An extra feed pump may be connected as a fire pump, and should be used regularly for some such service as washing out boilers, to ensure its being in good order. Attention to surface and bottom flues is, of course, a daily duty. As to fittings use some one kind of valve; get a good kind and stick to it. Price should have no place in the first choice of valves. Get a good one with removable seats and discs and you will save a world of trouble and a deal—not an electric light deal—of money in a few years time. Let me remark that everything we have in bottom blow offs has failed except plain plug valves. The failure seems to come from scale, which will stick under the gates and seats, and bend them out of shape when closed. An extra large valve in the blow-off discharge is desirable in case of a failure of a blow-off valve.

In piping of all kinds discard elbows and use only T's. You will frequently save taking down an entire line of pipe to make some connection by so doing, and the T's are most convenient for examining and cleaning the pipes. You should also obtain all your fittings and pipe of one party, to ensure good fits. Threading tools are seldom alike, and a small variation will give endless trouble with leaks.

Cover all steam pipes, and remember in choosing a covering that it is not the material which you cover with which makes the non-conductors, but the confined air spaces in the same. Get air spaces, and get them so

Digitized by Google

arranged that the air cannot circulate between hot and cold surfaces. Remember also that you can tell nothing by the feeling of the outside of a covering about its effectiveness. Sensations of heat and cold are intensified by the conducting capacity of the object touched. A piece of metal attached to a steam covering till hot will convince you of this. It can be no warmer than the covering, but it feels so.

In touching on the electrical apparatus I feel that I am treading on delicate ground, and I shall try and step accordingly. The principal elements of ordinary wear in dynamos are :—

(1) Burned coils in the armature ; (2) wear of brushes ; (3) wear of commutator ; (4) wear of boxes or journals.

In regard to burned armatures I will say that judgment should be exercised in the choice of a system as to the liability of such an accident, and this being determined choose a machine whose armature is most readily repaired. Gramme and similar ring armatures are probably the most easily repaired. Siemens armatures and all armatures with lapped coils must go to the factory for a good job.

As to brushes, the cheapest by far, both in first cost and wear, are the single leaf, split brush. Multiple brushes are usually used in commutators with many segments, and there seems to be some relation between the number of segments and wear of brushes

Commutators of many segments are less desirable than those of few. The segments can usually only be changed by putting on a new commutator and they seldom wear true. The segments on commutators of fewer bars are usually arranged to be easily removed and can then be turned up and replaced.

Plain babbited boxes or bronze bushings are about on a par for convenience in renewal. Bronze has the advantage of not being liable to melt out and cause a shut down, and a little patience will almost always succeed in cooling them down. For belting probably nothing is better than double pasted leather belts if well made. For large belts a few rivets must be put in.

Arc lamps should be devoid of glycerine, and not easily shaken out of adjustment. The lighter and smaller lamps are the better for handling. Arrange all inside wiring of some first-class high insulation wire, especially on high tension circuits.

In the Keystone station in Philadelphia I first saw oil conducted to each machine oiler and cylinder cup in pipes. I heartily approve this system as a saving both of oil and waste.

In conclusion, I will suggest two rules to govern central station construction.

1. Expend every dollar, which will return 10 per cent. on its investment in addition to maintaining itself, including, of course, interest, taxes and wear and tear.

2. After carefully investigating, estimating and planning out the capacity of your station, make a large guess as to what you require, and multiply by two.

COMPANIES' MEETINGS & REPORTS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

An extraordinary general meeting of this Company was held yesterday at the offices of the Telephone Company of Austria, 53, New Broad-street, to confirm the following special resolution passed at the extraordinary general meeting, held on the 2nd inst., at the City Terminus Hotel :—

"That the capital of the Company be reduced from £243,787. 10s. divided into 224,850 shares of 15s. each and 75,150 shares of £1 each, to £232,545 divided into 224,850 shares of 14s. each, and 75,150 shares of £1 each, and that such reduction be effected by returning to the holders of the 224,850 shares that have been issued paid-up capital to the extent of 1s. per share, and by reducing the nominal amount of such 224,850 shares to 14s. each."

Mr. C. L. W. FitzGerald presided, and was supported by all the other members of the Board.

The SECRETARY (Mr. Chas. Curtoys) having read the notice convening the meeting, and the minutes of the ordinary and extraordinary meetings, the latter being confirmed and signed by the Chairman as correctly entered,

The CHAIRMAN, in moving the confirmation of the foregoing resolution, remarked that he need say very little on the subject to which it had reference with the exception that, should it be confirmed, the Directors would at once take steps to get the Court to permit them to return the 1s. to the shareholders. It was impossible for him to say how long time the proceeding would take, but it would be carried into effect as quickly as possible.

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the motion, which was unanimously agreed to, and the proceedings terminated,

South of England Telephone Company (Limited).

Report of the Directors for the twelve months ended 30th April, to be presented to the shareholders at the third ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Tuesday, the 28th inst., at one o'clock :—

During the past year the sum of £16,077. 9s. 5d. has been expended on account of capital, making a total of £27,926. 19s. 11d. The revenue account shows a gross income of £7,584. 15s. 8d., and a net credit balance of £1,059. 11s. 5d., making, with the sum of £727. 3s. 7d. brought forward from last year, an available balance of £1,786. 15s., from which has to be deducted £728. 6s. for preference dividend, leaving a balance of £1,058. 9s., which it is proposed to carry forward. The heavy snowstorm of the 26th December last, which was immediately followed by very strong winds, had a most disastrous effect upon the Company's wires ; the damage, however, was fortunately confined to the northern districts. The entire expenses attending the reconstruction of the lines have been charged to revenue account. In carrying out the new work care has been taken to obviate, as far as possible, a recurrence of a similar disaster. During the past year trunk lines have been run as follows :—Norwich to Great Yarmouth, Northampton to Wellingborough, Chatham to Maidstone, Dover to Folkestone. A trunk line between Margate and Ramsgate is in process of construction, and arrangements are also being made for connecting Brighton and Worthing, and Brighton, Lewes and Eastbourne. The growth of the exchange and private line business may be considered favourable, as shown by the following statement :—

	Exchange Subscribers.	Private Line Renters.
April 30th, 1886	687	248
April 30th, 1887	1,130	348
Increase	443	100

Telephone exchanges are now open at the following places :—Brighton, Cambridge, Chatham, Dover, Eastbourne, Folkestone, Great Yarmouth, Hastings and St. Leonards, Ipswich, King's Lynn, Luton, Maidstone, Margate, Northampton, Norwich, Oxford, Peterboro', Ramsgate, Reading. Mr. D. O. Bateson retires from the Board by rotation, and, being eligible, offers himself for re-election. The shareholders' auditor, Mr. J. Weise, retires, and is eligible for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 17th inst. amounted to £4,663.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—The coupons due on July 1 on this company's Five per Cent. Mortgage Debentures will be paid by Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C. Coupons should be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 17th inst. amounted to £3,841, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended the 15th inst. are £2,785, as compared with £2,452 in the corresponding period of 1886.

NOTES.

THE UNITED TELEPHONE COMPANY.—The annual report of this company will be found in another column.

NAPLES.—The Municipality Council of Naples has passed a resolution making the electric light compulsory in the theatres of that town.

THE TECHNICAL COLLEGE, FINSBURY.—We have been requested to make known that Friday, July 15th, has been fixed for the date of the annual students' *conversazione* of the City and Guilds Technical College at Finsbury.

TELEGRAPH EXTENSION IN THE WEST INDIES.—The Madrid *Gazette*, of June 26th, contains a royal decree granting the D José Rafael Vizcarrando the right to establish and work a telegraph cable between the islands of Cuba and Hayti.

THE ROYAL SOCIETY.—At the annual meeting of the Royal Society just held at Burlington House the following, amongst others, were elected Fellows: Prof. J. A. Ewing, B.Sc.; Prof. G. Forbes, M.A.; Prof. J. Milne, F.G.S.; Prof. Oliver J. Lodge, D.Sc.

THE PHYSICAL SOCIETY.—The abstract of the proceedings of the Physical Society, which will be found in another column, contains some very interesting notes by Profs. Ayrton and Perry on "Magnetic Resistance" and on a "New Ammeter and Voltmeter."

OBITUARY.—The death is announced of Professor Cecchi, of Florence. Professor Cecchi was the author of an important work on seismology, and of various papers on electrical subjects. He also devised an arc lamp, an electro-motor, and an induction machine.

THE ESCURIAL.—The famous palace and monastery of the Escurial has recently been supplied with a small installation of arc lamps. The chapel is lit with eight arcs of 4,000 candles, and eight more of the same size are placed upon the summit of the loftiest tower.

THE PARIS-ROUEN TELEPHONE LINE.—This line was opened for public service on the 25th inst. The charge is 1f. for five minutes' conversation. At present communication is only open between the Bourses, and the charge of 1f. is payable whether the individual wanted is or is not present when asked for.

PERSONAL.—It has been stated this week in certain quarters that Mr. Crompton is seriously ill. We are, however, glad to be able to state that the rumour has no foundation; in fact, Mr. Crompton is in his usual state of health, but is at present in Vienna superintending the carrying out of some important work in that city.

MEXICO.—The authorities of the city of Mexico have renewed the contract with the electric light company for a term of three years on the following basis:—The streets are to be lighted by the company 2,750 hours per annum; for each lamp the company is to receive $37.50 per annum, for each electric arc of not less than 2,000 candle-power $31.25. per month.

SEVEN HUNDRED AND NINETY SHEEP KILLED BY LIGHTNING.—A Reuter's telegram from Cape Town states that on the 17th of May last, at the farm of Biesjesdam, near Victoria West, a small house around which a flock of sheep were sheltering was struck by lightning, which shattered the gable of the building to its foundation, and killed no less than 790 out of the flock of 1,430 sheep.

THE VAN RYSSELBERGHE SYSTEM IN JAPAN.—Van Ryssel-berghe's system of simultaneous telegraphy and telephony has been tried in Japan between Takaraki and Jokogawa. Professor J. Fujioka, of the College of Engineers at Tokio, who has been instructed to examine the system on behalf of the Japanese Government, has reported that the method is well adapted for use upon the principal telegraph lines of the country.

SALE OF ELECTRICAL PLANT.—A large quantity of electrical and engineering plant, the stock of Messrs. Corner, Allan and Co. (Limited), Wandsworth Bridge Wharf, Fulham, was sold by auction on the 23rd and 24th ult, by Messrs. Wheatley Kirk, Price and Goulty, of 52, Queen Victoria-street. Amongst the electrical apparatus were a number of dynamos of the Crompton, Bürgin, Gramme, Oppermann, and Ball types, which realised average prices.

BRITISH AND AMERICAN UNITS OF LENGTH.—United States and British measures of length are commonly considered to be the same; but, in fact, the British are shorter than the United States by about 1 part in 17,230, or 3·677 inches in a mile.

U.S. inch = ·025401 metre.	British inch = ·0253995 metre.
U.S. foot = ·30481 ,,	British foot = ·304794 ,,
U.S. yard = ·914430 ,,	British yard = ·914382 ,,

THE ELECTROLYTIC PRODUCTION OF ALUMINIUM.—It is announced that Dr. Kleiner, of Zurich, has succeeded in obtaining aluminium by the direct electrolysis of cryolite, a mineral consisting of a compound of sodium and aluminium fluorides, $3\,NaF + AlF_3$. But Kleiner's method only yields at present about $3\frac{1}{2}$ grammes per horse-power hour, while by the Cowles process at least three times that quantity is obtained. A company has recently been formed in Belgium to work the latter process.

THE JUBILEE BALL AT THE GUILDHALL.—On the occasion of the Jubilee Ball at the Guildhall on the 28th inst. the temporary crush room in the Guildhall courtyard, which was made of a wooden framing, was lit throughout by Messrs. Woodhouse and Rawson with about 80 incandescent lamps of 10 and 20 candle-power. These were all fitted with elegant shades suspended with silk cord from the roof, the colours being chosen with very good taste to harmonise with the character of the decorations. E.P.S. accumulators were used to supply the current.

THE CITY AND GUILDS OF LONDON INSTITUTE.—On Monday afternoon, July 4th, after the laying of the foundation stone of the Imperial Institute by Her Majesty the Queen, the attendance of the visitors is requested at an inspection of the Central Institution in the Exhibition-road. The several laboratories and workshops of the Institution will be open to view, and there will be an exhibition of the work executed by the students of some of the technological classes that have been established in different parts of the kingdon in connection with the Institute.

"ELECTRICAL PLANT."—*Electrical Plant*, a monthly register of new and second-hand electrical plant, apparatus, fittings, &c., is the title of a new monthly trade circular issued by Messrs. Wheatley Kirk, Price and Goulty, the well-known auctioneers. We believe that this circular will supply a want which has long been felt in affording a ready means of ascertaining the whereabouts of second-hand electrical plant, and we wish the publishers every success in their venture. The first number has evidently been got up with considerable care, and contains a very extensive list of electrical apparatus of all kinds.

TELEPHONY AND THEATRES.—The Telephone Company at Rome have been devoting their attention to perfecting arrangements for transmitting opera music by telephone. The best

Digitized by Google

results have been attained by means of a microphone, of which the contacts are placed in the focus of a parabolic reflector. Instead of being placed at the front of the stage, it is found preferable to hang the transmitters under the columns of the first row of boxes. These trials have been made at the Théâtre National during the representation of *Puritani*, and it is said that the transmission both of solos, choruses, and orchestration has attained an astonishing degree of clearness and accuracy.

Curious Manifestation of Electric Action.—In a printing office at Mayence which has been paved with asphalte some extraordinary electrical effects have been manifested during the late spell of dry weather. The paper as it passed through the machines is described as giving off a rapid succession of brilliant sparks. On presenting the hand sparks several inches in length could be obtained from the framework of the machines. At one time the discharges were so violent that the men refused to go on with their work. All this is the more remarkable because paper is usually damped before being printed on. However, the *Elektrotechnischer Anzeiger* is our authority for the story.

Admiralty Contracts for Dynamos and Engines.—The Admiralty have lately contracted for 35 sets of dynamos and engines of various sizes and types. In another column will be found the full text of the specification issued by the Director of Naval Stores. It will be observed that the limitation as to the rise of temperature permitted in the dynamos under full load is very stringent. No doubt it is found useful to stipulate for a very high factor of safety in this direction, so as to secure a machine which may be trusted to work in any climate, and, if necessary, at an output considerably beyond the normal. At the same time, we are rather inclined to doubt whether 20°F. is not an almost impracticable limit for the increase of temperature.

Query: the Discovery of a New Motive Power?—In *La France* of June 13th, 1887, there appeared a paragraph of the usual stock-in-trade character of the non-technical press when writing on anything scientific. "M. Maiche," we are told, "has invented a new machine by means of which we shall obtain the electric light at a price less than half what it costs to-day. This machine, based upon principles entirely novel, leaves far in the rear everything previously known. It is a true revolution in the art of electric lighting." It is manifest that nothing but the discovery of a new motive-power can possibly justify the statement as to the reduction of cost, and we have therefore only to remark that the paragraph is couched in altogether too modest terms.

Self-Exciting Alternating Current Dynamos.—The possibility of causing an alternating current machine to excite its own field by commutating a portion of the armature current probably did not escape the observation of the earlier dynamo makers. There is, however, some practical difficulty in the way of carrying out the arrangement, owing to the necessity for a very accurate adjustment of the brushes to avoid sparking at the commutator. In the Zipernouski-Déri machine the proper length of the brush and its exact position are carefully marked by the constructors. In case of sparking it is worth noting that if the flashes are long and brilliant the brushes require to be moved against the direction of rotation, while if short and not very vivid the adjustment must be made in the other direction.

The Variation of the Resistance of Lamp Filaments.—Some experiments, communicated to the American Institute of Electrical Engineers by Prof. W. A. Anthony, serve to show that the resistance of an incandescent lamp filament does not decrease continually as the difference of potential at the terminals increases. After a certain point the resistance passes through a minimum value, and again increases. The point of minimum resistance, however, varies widely even with lamps of the same type. Prof. Elihu Thompson remarked that he had noticed the same fact, and added that when incandescent lamps are placed in series and traversed by a constant current he had found that their resistance tended at first to decrease, but after a certain time it again augmented, and this phase continued until the temperature became sufficiently high to destroy the lamp.

"Electric Meteorology."—Mr. G. A. Rowell, of Oxford, sends us a pamphlet with the above title, in which he discusses the cause of the changes in magnetic declination. He adduces evidence to show that the European and American magnetic poles are coincident with the centres of greatest cold for the two continents. Hence he attributes the shifting of the magnetic poles to the same series of astronomic and geologic causes which produce the secular changes in climate. This theory leads to the uncomfortable conclusion that as the magnetic declination in this country continues to decrease, so our winters will increase in length and severity. Without laying undue stress on the point, the author is certainly able to appeal to our recent melancholy experiences as an argument upon his side. If our readers will refer to page 252 of our previous volume they will find further information, not without interest, concerning Mr. Rowell and his scientific career.

The Indo-European Telegraph Service.—The *Homeward Mail* contains the following paragraph:—"Mr. Henniker Heaton, as the censor of Posts and Telegraphs, may be interested to learn that Colonel Holland, of the Indo-European Telegraph Company, recently stated that if the management of the Indian Government lines were equal to that of the company's, a message from India should arrive in England in about forty to forty-one minutes, instead of, on an average, upwards of two hours, as was the case at present, and that this was a matter which the Government of India ought certainly to be able to remedy." On the other hand the *Englishman* publishes the following short paragraph, which is perhaps intended as a semi-official answer to the above:—"The average time occupied in the transmission of messages from Calcutta to the United Kingdom by the Indo European Telegraph Company during the last fortnight in May was one hour thirty-nine minutes."

Lincoln.—On the night of the Jubilee celebration the great tower of Lincoln Cathedral, which is 271ft. in height, was illuminated by 32 arc lamps, of 200 candle-power, or in all 64,000 candles. Four of these lamps were placed on the top of the four pinnacles, at a height of 40ft. above the summit of the tower itself. Lincoln Cathedral stands upon a hill some 300ft. high, so that the total height of the lamps above the level of the flat country around the city was between 500ft. and 600ft. The effect of the illumination was very fine, the lamps appearing like a brilliant crown in the sky; and, as may be supposed, the light was seen from very great distances. The installation was carried out by Messrs. Robey and Co., the well-known engineers, of Lincoln, who employed on this occasion the plant which has been used for the electric lighting of their own works for the past seven years. We are indebted to Messrs. Robey and Co. for a very fine photograph of the cathedral, showing the lamps in place upon the summit of the tower, and the method adopted for supporting the four lamps upon the pinnacles. We learn also that the light was seen as far north as Doncaster and York, southward as far as

Boston, Peterborough, and Ely, and far into the midland counties.

On the Relation between the Peltier Effect and the Contact Difference of Potential of Two Metals.—The contact difference of potential between any two metals depends solely upon the nature of the metals chosen, and upon their temperature. Similarly, the Peltier effect between two metals (or the liberation of heat which takes place when a current of electricity passes in one direction from one metal to another) depends solely for a given current upon the nature of the metals, and upon their temperature. It has therefore been supposed that a relation of direct proportionality existed between the contact difference of potential of two metals and their coefficient for the Peltier effect. The experiments of M. Pellat have, however, cast very considerable doubt upon the truth of this assumption. M. Duhem has also recently investigated the subject, and in a note read before the French Academy on June 6th he enunciates the following theorems:—(1) The coefficient of the Peltier effect is proportional to the product of the absolute temperature and of the first differential coefficient of the contact potential with respect to the temperature. (2) The electromotive force of a thermo-electric couple is equal (in electrostatic units) to the excess of the contact potential between the two metals at the cold junction over the contact potential at the hot junction.

Electric Shocks.—Some impromptu experiments upon the physiological effects of the electric currents, or, more properly, difference of potential, have recently been related by Dr. Zacharias, of Berlin. On one occasion when walking along the electric tramway at the mines of Hohenzollern the Doctor happened to slip, and in falling caught hold of the conductor, which was at a potential of 300 volts above the rails. This, however, "made little impression upon him." Another time, having incautiously taken hold of the framework of an arc lamp supplied with alternating currents at a potential of 200 volts he was unable to leave go until someone came to the rescue by lifting him off the ground. On this occasion the soil was very damp; in dry weather he found that little or no inconvenience was experienced. The most painful experience which Dr. Zacharias has hitherto encountered occurred in an attempt to disconnect a dynamometer under a potential of 1,500 volts. On this occasion a severe and painful shock was felt through both arms; but still no serious results ensued. Stories of this character are, however, told by most electricians who have to do with dynamos, and although, happily, accidents of a fatal or even of a serious character are so rare as to be almost unknown, yet the immunity of the past should not be permitted to encourage any laxity or foolhardiness in dealing with high tension machines.

Dun's Portable Battery.—A battery specially designed by Herr Dun for call bells and telephones and for medical purposes has been for some time in use in Germany, and is said to have given considerable satisfaction. The elements are zinc and carbon. The carbon, in the form of a hollow cylinder, is placed within the zinc, and is bored full of holes, which are filled with fragments of permanganate of potassium. The cylinder is wrapped on the outside with parchment paper, and is then filled with caustic soda in which the permanganate gradually dissolves. A piece of parchment paper is placed over the top of the cylinder, the zinc (also in the form of a cylinder) is placed in position outside, and the glass or porcelain vessel is then nearly filled with a hot solution of caustic soda to which a little starch has been added. This solution is poured in until both cylinders are entirely covered, and the liquid stands an inch or so above the upper surface of the carbon. On cooling the solution forms a gelatinous mass, like the "graphs" of various kinds which were so popular in this country a few years ago. Insulated conducting wires are, of course, led from the plates to suitable terminals. Finally, the outer vessel is filled to the brim with plaster of paris, or, if preferred, with paraffin, which is poured on the top of the starch jelly. By this means the permanganate solution is thoroughly protected from atmospheric action. The internal resistance is said to be low, and so also is the cost of the cell.

The Polarisation of an Electrode by Variation of Surface of Contact with a Liquid.—In the recent and important experiments by M. Pellat on the measurement of contact differences of potential (see *Electrician*, June 3rd, 1887, p. 81), the author made use of the phenomenon discovered by M. Lippmann that when mercury in contact with sulphuric acid forms a part of a closed circuit, containing also a galvanometer (but no battery), a momentary current is set up when the surface of contact between the metal and the acid is either extended or contracted. The experiment is more easily made with mercury than with other metals, but recently M. Knochkoll has observed the same effect with copper in contact with dilute saline solutions, and also with distilled water. The experiments were carried out in the Laboratory of Physical Research of the Sorbonne, and led to the conclusion that, accepting the hypothesis of MM. Lippmann and Pellat (vide *Electrician* loc. cit.), the actual contact E.M.F. of copper with a 2 per cent. solution of sulphate of soda lies between 0·304 volt and 0·348 volt. The experiments were made by the same method as was adopted by M. Pellat—that is to say, the E.M.F. due to an extension of the contact surface was balanced by an external and measurable difference of potential until a change of surface showed no current through the galvanometer. The external difference of potential was interpolated in the circuit by means of non-polarisable electrodes, consisting of copper in a solution of cupric sulphate. These results were brought before the French Academy on the 23rd ult.

Illuminations at Kensington.—Messrs. Crompton and Co. write us as follows:—"Besides the list of special lighting already published by you for the Jubilee celebrations, the Kensington Court Electric Light Company, which is making rapid progress in private house lighting, carried out the following:—A triumphal arch, close to the entrance of Kensington Palace, was brilliantly illuminated with six Crompton arc lamps, of 500 to 1,000 candle-power each. Mr. Hunt's private house, which was gaily decorated, was lighted outside with a powerful Crompton lamp of 4,000 candle-power. (This house has recently been supplied for a permanency with the electric light from the central station.) For Mr. Hall, fishmonger, who has lately introduced the electric light into his shop, a large V R, 16 candle-power, also two statuettes, carrying incandescent lamps of 32 candle-power in each hand. For Mr. Savage, a jeweller, the dates 1837 and 1887 in incandescent lamps of 16 candle-power. The above have had the illuminations continued consecutively from Friday week until Wednesday, the 29th. Besides the above supplied with current from the central station, special illuminations were fixed for Sir Richard Webster, which were driven from his own plant, and Mr. Crompton had his private house supplied with current in the same manner. Messrs. Barclay's bank in Lombard-street was very prettily lit up, the incandescent lamps forming the letters V R showing up to good advantage. There were very few people who had electric light installations of their own, or had command of the current from elsewhere, who omitted to make some pretty and striking device, showing how admirably adapted the electric light is for carrying out illuminations."

TEMPORARY INSTALLATIONS—JUBILEE AND OTHERWISE.—Messrs. Shippey Bros. send us the following notes:—"The following installations, amongst others, have recently been carried out by Messrs. Shippey Bros.: A 12,000 candle-power arc light plant, 'Brush' system, in the grounds of Captain Hargreaves, The Mount, Bishopstoke. The lighting of the new Tower Gardens, Herne Bay, which were opened on Saturday last, with a 12,000 candle-power Gülcher plant, consisting of six lamps of 2,000 candle-power. The lamps were placed upon scaffold poles 45ft. high in the gardens, which face the sea, and were seen for many miles around the coast. The Jubilee Hall, recently built by Mr. Collard, of Herne Bay, was lighted by sixty low resistance lamps of thirty volts, run two in series, enclosed in specially designed globes, with electro-plated fittings placed at equal distances round the hall, and the centre chandelier studded with numerous silver stars, in which the lamps were embedded, an arrangement which is described as having produced a very pleasing effect. Several two and three light Pieper arc lamp plants were supplied for the occasion of the Jubilee at Goole, Manchester, Blackheath, Belfast, Beltinge, and other places in the United Kingdom. For fancy coloured incandescent lamps, devices, and monograms, the demand has been very great, and many orders had to be refused. A specially-designed device of 300 small 10-volt 5 candle-power lamps, coupled 10 in series, was supplied to a well-known sportsman, mounted on a board covered with crimson velvet, with the following inscription, 'Fifty runs and not out.' This was fixed in front of the house, and run from a 100-volt circuit, above which was the portrait of the Queen, studded round with 50 2-volt light blue fairy lamps, fed from one large E.P.S. accumulator of 60 ampere-hours capacity. A private house in St. Helen's-gardens, Bayswater, was illuminated outside with 40 coloured and opaline incandescent lamps, and also a private residence in St. George's square, Belgravia. About 500 coloured lamps were supplied for the illuminations at Lancaster, Bolton, and Leicester. At Ferdale House, Leamington-gardens, North Kensington, the front windows were all lined with small 8-volt lamps, set in silver rosettes, about 3in. apart, while twelve 50 candle-power lamps lighted the upper portion of the house, being hung from the bay windows."

PARIS.—THE MONTMARTRE CENTRAL LIGHTING STATION.—We briefly chronicled in our last issue the opening of the central lighting station of the Compagnie Française d'Eclairage Electrique in the Rue Drout. This is the first scheme of the kind out of the numbers which have been talked about from time to time which has actually come into existence in Paris, and as such it is certainly a noteworthy event. The plant consists of two engines of 60 horse-power and four Gramme machines of the so-called "*type supérieur*." There are also held in reserve 120 accumulators of sufficient capacity to take the place of one of the dynamos in the event of a breakdown. The supply is maintained night and day. The machines give each 200 volts, and are connected two in parallel, the two pairs serving separate and independent circuits. The mains are, however, laid out upon a system termed "*en boucle*" (or linked), of which we do not remember to have heard before, and which is not clearly described by our French contemporaries. It is said, however, that the arrangement effects a distribution at constant potential at all points, and that the two circuits can be worked either separately or in series, or if desired in parallel, and in the latter case the distribution reverts to the Edison-Hopkinson three-wire system. The conductors are carried overhead, and consist of bare stranded copper wire. They are supported by porcelain insulators, and the wire is coated with india-rubber for some distance on either side of the posts. The station is very dentrally situated for the district to be served, and up to the present only 1,400 lamps are in use in sixteen buildings, so that no especial difficulty has yet been experienced in arranging the conductors. Swan lamps of ten, sixteen, and thirty-two candle-power are employed. The consumers are charged for on the basis of current supplied at the rate of twenty centimes per ampere hour, at 100 volts, or about 1s. 7d. per unit. This is about 10 or 12 per cent. dearer than the price of gas at Paris for equal illumination. The current is measured by Cauderay meters. Some improvements have recently been effected by the Compagnie Française in this meter, chiefly by the substitution of a dynamometer action instead of the permanent magnets hitherto employed. This is undeniably a step in the right direction, and we anticipate that before long more will be heard of the Cauderay meter in our own country. We are glad to learn that since the opening of the station there has been so great an increase in the demand upon the company that it is already in contemplation to increase the capacity of the plant to 6,000 lamps.

LIGHTING OF A NEWSPAPER OFFICE AT IPSWICH.—The office of the *East Anglican Daily Times*, at Ipswich, which has recently been rebuilt at considerable cost, is lighted throughout by electricity. From a special "Jubilee" edition of the paper we take the following account of the installation:—"The necessary machinery and fittings were supplied by Messrs. Paris and Co., electrical engineers, of Gothic Works, Norwich, and fixed under the personal superintendence of Mr. Paris. The electricity is generated by a 150-light dynamo, fixed in a specially constructed apartment in the basement. It is fitted with Messrs. Paris and Scott's new armature winding, an invention by which the resistance of the magnetic field is considerably reduced, and a larger output of electricity is secured than could be obtained with any other machine of a similar size. The dynamo runs at the rate of 800 revs. per minute, and gives an output of 100 amperes at 100 volts. On a recent occasion the machine was thoroughly tested, and it was found that after running eight hours with an average of 87 amperes passing through the armature the latter was not in the slightest heated, thus showing that the strength of the current might be nearly doubled without any material loss. The current is conducted through the building by six different circuits—one for the machine and engine rooms, one for the front offices and passages, two for the composing room, one for the editorial and other rooms on the first floor, and one for the lantern and turret room. Each circuit is governed by a magnetic 'cut-out,' patented by Messrs. Paris and Scott, which can be so arranged that if the strength of the current is increased by the smallest percentage beyond what the lamps are supposed to take the current will be cut off before any injury is done. These 'cut-outs' can also be utilised as switches. The return current is brought back by two separate mains, in which Hedges' fuse is insulated, so that both negative and positive wires are carefully protected. All the fittings here and throughout the building have been fixed according to the rules of the Phœnix Fire Office. The 'cut-outs' are mounted on slate slabs, and the switches on specially manufactured earthenware plates, so that no mechanical arrangement for turning the lights on and off is in immediate contact with the woodwork or brickwork in the building. The machine room is lighted by a number of small lamps placed directly over the printing and folding machines, and covered with green shades, which take the light off the eyes of the workmen, and throw it direct on to the work. In the centre of the room there is a handsome electrolier, with five lights, and a smaller one at each end with three lights each. The lights in the publishing room and front office are arranged to meet the requirements of the departments.

Digitized by Google

In the front office the principal illumination is supplied by a seven-light electrolier, fitted with ground glass lamps and ice glass shades, which have a pretty and artistic effect. In addition to these are a number of movable lamps, which can be adjusted to any desired height to suit the convenience of the clerks. The lamps in the passages are fitted with artistic hexagon glass shades. In the composing room there are fifty small lamps, all covered with green shades to deflect the light on to the "cases" and "stones," and to protect the eyes of the compositors. It is in this room, more perhaps than any other, that the advantages of the electric light are apparent. Anyone acquainted with the interior of the composing room of a daily paper must have experienced the stifling sensation which is produced by fifty or sixty gas jets burning all the evening and more than half through the night. The air becomes thoroughly vitiated, and necessarily injurious. By the introduction of the electric light into the composing room it is hoped to secure a healther atmosphere, and the experience up to the present has been more than satisfactory, for after the lights had been burning eight hours there was scarcely a perceptible increase in the temperature of the room. The smaller rooms on this floor are also suitably lighted, and where necessary small electric table lamps are supplied. These lamps can be moved to any part of the room, and when not in use can be fixed as bracket lamps to the wall. Each lamp is governed by a separate switch, so that the light can be turned on or off as required. The handsome wrought-iron lantern on the front of the turret is supplied by a separate current, and is fitted with eighteen lamps, which produce a very brilliant light."

BANQUET TO PROF. TYNDALL.—On Wednesday evening last a large and distinguished company attended a banquet at Willis's Rooms, which was held as a formal recognition of the great services rendered to the cause of scientific progress by Prof. Tyndall on his retirement from the Chair of Natural Philosophy in the Royal Institution. The chair was taken by Prof. Stokes, President of the Royal Society, who had acted as chairman of the organising committee. Among those who had consented to serve on the committee were the Marquis of Salisbury, the Duke of Devonshire, the Duke of Argyll, the Right Hon. J. Inglis, Earl of Rosse, Earl Granville, Sir F. Abel, Prof. Adams, and many others holding distinguished positions in connection with scientific and learned societies, and Mr. J. Norman Lockyer and Mr. A. W. Rücker had acted as honorary secretaries to the committee. Among those who attended the dinner were the Earl of Derby, Earl Bathurst, the Earl of Lytton, Sir F. Leighton, Lord Rayleigh, Lord Thurlow, Sir J. Lubbock, M.P., Sir F. Bramwell, Sir H. Roscoe, M.P., Sir Lyon Playfair, M.P., Prof. J. C. Adams, Prof. Asa Gray, Prof. Flower, A. Geikie, Dr. Frankland, Dr. Debus, W. Crookes, Prof. B. Stewart, Prof. Judd, and General Strachey. The Chairman, in proposing the toast of the evening, dwelt upon the many profound and beautiful investigations of their illustrious guest on some of the most delicate questions of physical science, especially those upon the diathermancy of gases and the effect of aqueous vapour upon solar and terrestrial radiation. He dwelt also upon the unrivalled power of clear exposition, and of the charm of lucidity which has rendered Prof. Tyndall's writings so potent a factor in the spread of scientific teaching. The toast of Prof. Tyndall's health was drunk with great enthusiasm. Prof. Tyndall on rising to respond was received with loud cheers. In the course of a most interesting address, after warmly acknowledging the high compliment paid him, he spoke as follows:—"In 1850, during a flying visit from Germany to England, I stood for the first time in the bright presence of Faraday. In February, 1853, I gave my first Friday evening lecture in the Royal Institution; and three months afterwards, on the motion of Faraday, the old Chair of Natural Philosophy, which had been filled at the beginning of the century by Thomas Young, was restored, and to it I was elected. It causes me genuine pleasure to think that I shall be succeeded in that chair by so true and so eminent a man of science as Lord Rayleigh. It is not my intention to overburden you with egotism to-night; but, casting an earnest glance back upon the past, a few words seem due from me to the memory of one or two of the group of good men, no longer with us, with whom I was so intimately associated. Regarding Faraday, I will confine myself to stating that years have not altered my estimate of the beauty and the nobleness of his character. He was the prince of experimental philosophers; but he was more than this—in every fibre of his mind he was a gentleman. I might point to the industries which affiliate themselves with Faraday's discovery of benzol, and with his discovery of the laws of electrolysis. But I need not go further than the fact that in this our day a noble and powerful profession has been called into existence by his discovery of magneto-electricity. The electric lamps which mildly illuminate our rooms, the foci which flood with light of solar brilliancy our railway stations and public halls, can all be traced back to an ancestral spark so small as to be barely visible. With impatient ardour Faraday refused to pause in his quest of principles to intensify his spark. That work he deliberately left to others, confidently predicting that it would be accomplished. And prompted by motives both natural and laudable, but which had never the slightest influence on Faraday, others have developed his spark into the splendours which now shine in our midst. It would be a handsome Jubilee present, if it were a possible one, to roll up the career of Faraday into portable form, and to offer it to the Queen as the achievement of one of Her Majesty's most devoted subjects during her own reign. Faraday's series of great discoveries, however, began in 1831, which throws his work five or six years too far back. During the rest of his fruitful life he was a loyal son of the Victorian epoch. But, passing beyond the limitations of the individual, what is science as a whole able to offer on the golden wedding of the Queen with her people? A present of the principle of gravitation—a handing over to Her Majesty of the bit and bridle whereby the compelling intellect of Newton brought the solar system under the yoke of physical laws—would surely be a handsome offering. I mention this case of known and conspicuous grandeur in order to fix the value of another generalisation which the science of her reign can proudly offer to the Queen. Quite fit to take rank with the principle of gravitation—more momentous if that be possible—is that law of conservation which combines the energies of the material universe into an organic whole, that law which enables the eye of science to follow the flying shuttles of the universal power, as it weaves what the Earth Spirit in 'Faust' calls 'the living garment of God.' This, then, is the largest flower of the garland which the science of the last fifty years is able to offer to the Queen. The second generalisation is like unto the first in point of importance, though very unlike as regards its reception by the world. For, whereas the principle of conservation with all its far-reaching and, from some points of view, tremendous implications, slid quietly into acceptance, its successor evoked the thunder peals which it is said always accompany the marriage of thought and fact. For a long time the scent of danger was in the air. But the evil odour has passed away; the air is fresher than before; it fills our lungs and purifies our blood; and science in its Jubilee offering to the Queen is able to add to the law of conservation the principle of evolution."

INCANDESCENT LAMP MANUFACTURE.—XVIII.

BY J. SWINBURNE.

Exhausting Continued.

The valve arrangement in connection with the writer's pumps was found the best for factory work, but for experimental use a slight modification is advisable. This is shown in Fig. 18. An S tube is inserted between the little bulb and the bulb of the pump. The mercury on falling not only leaves enough to seal the valve, but also leaves a little in the bend of the S tube. If there is any water in the pump this shows it immediately, as its vapour has enough tension to prevent the mercury remaining in the bend. If the amount of water vapour is very small, it is left in the small bulb, so that the vacuum in the large bulb is as perfect as possible.

When the vacuum is very good, the mercury is not raised enough to lift the valve every time, but just enough to discharge into the little bulb. When the discharge of from ten to twenty strokes has accumulated in the little bulb the mercury is raised so as to work the valve. The whole discharge of twenty strokes is thus accumulated in a little bubble on the side of the valve tube. As this valve itself is under a pressure of not more than half-an-inch, it represents a vacuum sometimes as high as one in several million, according to the usual measurements of high vacua.

This S tube can be used without the valve, but it must then be made longer, as the attraction of the mercury for itself and its inertia make a longer tube necessary than would be needed to hold against the pressure alone. Care must be taken as to the bore of the S tube; it must not be larger at the point *a* than at *b*, for the attraction of mercury for itself makes it tend to flow towards the larger part of a small tube. Though the S tube for exhausting into a mechanical vacuum was in use by the writer for some time, it was abandoned because when the lamps were nearly finished the shock of the rising mercury against the mercury in the bend often punched out a little piece of glass. When this happened not only was the pump itself broken, but the mercury went round into the phosphoric tube and into the lamps themselves, and the whole had to be replaced. Many other arrangements of valves or their equivalents have been tried, but without getting anything better.

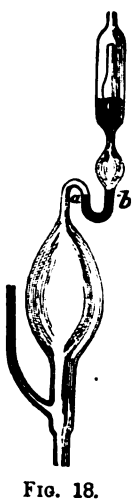

Fig. 18.

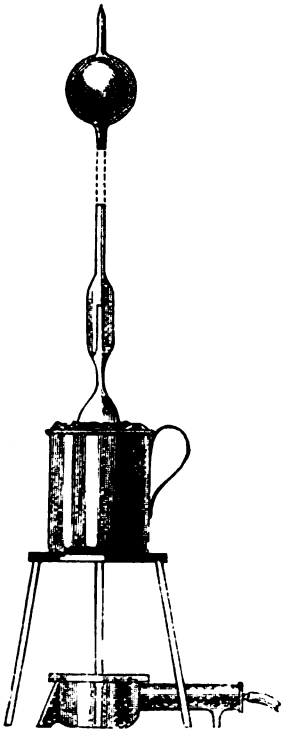

Fig. 19.

It need hardly be remarked that hand-worked taps or valves opening directly into the air are of no use, as not only water vapour, but air itself, will adhere to the surface of the glass under pressure

The phosphoric tubes are rather troublesome. The writer has tried various other drying substances. Sulphuric acid boils, and the vapour goes into the pump; zinc chloride, soda lime, and calcium chloride either do not dry the air enough or themselves give off vapour under the high vacua obtained by the pumps just described. Even phosphoric anhydride itself is sometimes troublesome. When wetted a little after some use it boils slowly. This may be due to its giving off some of the water it has absorbed, or to air coming off the glass underneath it, or the anhydride itself volatilising, or to its containing phosphorous acid. If phosphoric anhydride is very slightly heated in a good vacuum it will be found to volatilise and condense or sublime in the neighbouring tubes.

The writer has tried some experiments with the view of leaving residual vacua of vapours, which are decomposed by the heat of the carbon when the lamp is run, forming a solid, or a vapour of very low tension. As it seemed likely that water vapour formed a large part of the atmosphere in an ordinary incandescent lamp, it was attempted to decompose any vapour that might be left at the same time. The lamps were exhausted, and then filled with carbon disulphide vapour and exhausted again. This was repeated several times.

After each filling with carbon disulphide the lamps were strongly heated, so that the carbon disulphide might decompose any water vapour present. After exhaustion the vacua of the lamps were tested. The lamps were then run and tested again, the idea being that the carbon disulphide would be decomposed into carbon, which would be deposited, and sulphur, which would have a very low vapour tension. There was, however, no apparent difference.

A curious phenomenon was observed. During the exhaustion of the carbon disulphide lamps there were frequent explosions in the pumps. These did not break the pumps, though they made a sharp report. Tyndall observed the same effect in experimenting on carbon disulphide in his researches on absorption of heat by vapours (*Contributions to Molecular Physics*). Not only did these explosions occur without any apparent cause, but the result was a deposit not of sulphur, but of carbon in the form of soot. It would appear that the vapour is so prone to combine with the air that it does so at such a low temperature that the carbon is not burnt, sulphur dioxide and carbon being formed.

Chloroform, bromoform, and iodoform were tried, with the view of making residual vacua, in which water could not exist; but they tarnish the mercury in the pump.

The writer has tried many experiments, with the object of making the exhaustion of lamps quicker and better by adopting other methods altogether. It would make this series of articles too long if many of these were described, but it may be as well to mention a few, as some of them throw some light on the difficult subject of high vacua.

A lamp had a long tube fixed to its nose (Fig. 19). It was then filled with mercury up to the sealing point, and placed in an iron cup full of iron filings and heated. During this part of the experiment a globe was attached to the tube and exhausted, as otherwise the ebullition always bursts the lamp. As the lamp got hotter little bubbles of air collected on the glass, so that the lamp looked as if it was covered with dew, though of course the bubbles were inside. After some time the bubbles began to detach themselves, and when the boiling point of mercury under that pressure was reached brisk ebullition was set up. No bubbles adhered to the glass then, so it appeared that the glass was freed from air. The bulb was then removed, the tube itself was then heated little by little, mercury being added and boiled till the whole was like a boiled barometer tube. Several lamps burst under the pressure of the mercury, and it was very difficult to boil the mercury in the small tube, as it spurted about. When the whole was cool it was inverted under mercury, and the mercury in the lamp ran out, leaving a Torricellian vacuum. A sort of air trap was inserted just above the lamp, the mercury never being allowed to uncover the end when inverted. The lamp was sealed off and the vacuum tested in the usual way. The vacuum was never better than those produced by the pumps. This is strange, but the chief difficulty was in boiling the mercury in the small

Digitized by Google

tube. The lamp full of mercury with a long tube attached is very difficult to handle, as the weight is considerable. This experiment was tried several times, sometimes with an empty bulb, so that the vacuum could not be spoiled by gas from the carbon.

Lamps were made which themselves formed the bulbs of little Geissler pumps. After exhaustion they were sealed off top and bottom and tested. This experiment was suggested on noticing the following phenomenon:—If the spark from an induction coil is passed from the lamps to the mercury of the pumps, so as to traverse the phosphoric tube, and the tube from it to the bulb of the pumps, a violet or bluish light is seen. As the vacuum becomes better, this turns green, and finally the only light visible is a few bright green patches on the glass. But before the whole of the tubing shows this—in fact, while it shows a bluish tinge—that part of the tube which was filled with mercury when the elevating pressure was on shows the bright green light. This looks as if mercury has the power of sweeping off the adherent film volume of air. It was easy to see the exact height the mercury had risen to by the sharp division between the bluish and the bright spotty green.

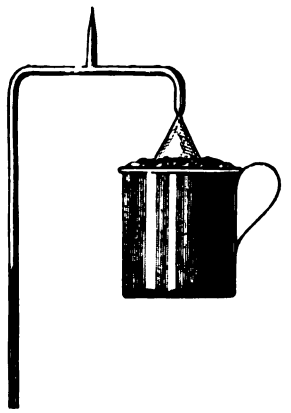

Fig. 20.

A lamp was arranged in the iron filing bath, and filled with mercury (Fig. 20). A bent tube was then sealed on, connected with a vertical Sprengel shaft. A small tube was sealed to exhaust as far as possible, thus bringing the mercury up the Sprengel tube about 30in. The mercury was then distilled out of the lamps. It condensed and ran down the Sprengel tube, so that any air that came off was taken down at the beginning of the experiments. Such experiments as these are very tedious, more especially as so many are spoiled by the lamps or tubes cracking, as it is difficult to work with such fragile apparatus and such a weight of mercury at such high temperatures.

CORRESPONDENCE.

TELEPHONIC INVESTIGATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Cherrill's article in *The Electrician* of the 24th June must have caused a curious sensation to many of your readers. The writer appears to have arrived at his difficulties in accepting the generally received theory of telephonic action by forgetting or overlooking some of the fundamental principles of acoustics. He says that "On this assumption we must admit that pressure must be in some instances *both increased* and *diminished* at the *same time*." Why? I can see no reason. Sound consists of a succession of "waves" or vibrations, such waves being actually successive differences in air pressure, when air is the medium. Any sound, however complex, can be represented by a curve corresponding to these pressure variations. As it is not possible to conceive of air being at the same time and place both diminished and increased in pressure, it follows that there is no reason to suppose that a telephone diaphragm on the pressure theory ought to be in two places at once. In the case of a complex sound, such as a note and its octave, the impression produced on our ears is due simply to the resultant. The effect on the telephone diaphragm is also simply the resultant. How can it be otherwise? The diaphragm at the receiving end executes similar movements and produces a similar sound. If Mr. Cherrill will be good enough to draw out the waves due to a note and its octave, and get the resultant wave, he will be able to see that his difficulty does not exist.

I have not Tyndall by me, and forget what he says about resultant tones, but I fancy he is using the words in a little different sense to Mr. Cherrill. In the particular case mentioned, since the upper octave of a note has twice as many vibrations as the primary, the resultant, *i.e.*, the difference, is equal to the number of vibrations of the lower note.

It would trespass too much on your space to follow Mr. Cherrill throughout his article, and I will therefore only ask him to explain the action of a phonograph on any other theory than the pressure theory. I put this case because the phonographic action is a purely mechanical one. If to render complex sounds the diaphragm has to be in two places at once, how can the needle point on the diaphragm make a series of impressions on the tinfoil capable of making the diaphragm move in such a way as to reproduce the original sounds and tone? In short, on what theory but the pressure theory can the phonograph be explained? And if the phonograph works from pressure effects, and it is admitted that the resistance of microphonic contacts varies with pressure, why seek further for an explanation? The pressure theory, as applied to the contacts, may be only a rough and inexact one; but so far as the diaphragm is concerned its truth is not open to doubt. I await Mr. Cherrill's own theory with some curiosity.—Yours, &c., Henry M. Sayers.

Lavender-hill, S.W., June 27, 1887.

THE FORBES NONPOLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As far as I understand Prof. Forbes' nonpolar dynamo, it consists essentially of a stationary exciting coil, wound in a circle, within a recess, in a circular armouring of iron, which forms the field portion of the magnetic circuit, and is stationary. The solid iron armature revolves in (and completes the magnetic circuit across) a gap inside the coils, so that as it revolves it must either drive the lines of force round with it, or it must be cut by them as it revolves.

My present difficulty is this—What prevents the lines from going round with the dynamo? I can understand that all will be well if the rings of magnetic force encircling the exciting coil are held *quasi*-fixed by the current in the coil; but if that were so it would answer as well to rotate this coil instead of the armature. But if this is not so, and the form of the field is such that Foucault or other currents cannot be excited in it, then there could be no resistance to prevent the armature carrying the lines round with it. But if, as I take it, the lines are only retarded in their revolution by the resistance to their passage through the field iron ring due to the generation therein of Foucault currents of large quantity, then the lines will only be carried round slowly by their reaction against the revolving armature. Would you kindly inform me if this view is correct? If it is, the stationary iron is as much armature in one sense as the revolving iron, and if the proper form be given to the machine, current might be collected from both the moving and the fixed portions of the iron circuit.—Yours, &c.,

R. Snowdon.

Staveley Ironworks, Chesterfield, June 28, 1887.

[It will probably be interesting if some of our readers will kindly explain their version of the accepted theory of dynamos as applied to the machine in question.—Ed. *E.*]

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: There is much truth in Mr. Mountain's remarks in your current number; but there is also a good deal to be said against his views.

When the owner or the manager of certain works or a

Digitized by Google

certain house has made up his mind to adopt the electric light, he has two courses open to him.

He may look round and see other installations, make inquiries as to the contractors who fixed them, choose a good firm whom from all accounts he can safely trust, and place himself in their hands, guarding himself by the simple plan of exacting a guarantee that everything shall go right for a certain time.

Or he may adopt Mr. Mountain's plan of calling in a consulting electrical engineer and placing himself in his hands. Now, it is obvious that very much must depend upon the amount of money which is to be spent. No doubt it would be very much better for all of us if we were to take professional advice before buying anything, even such commonplace articles as beef or mutton, tea or coffee; but we do not, and for two reasons—we cannot afford to do so, and we often do not know where to find anyone who can advise us efficiently on the matter; in fact, in practice we do our best to find out a good, honest tradesman conveniently near our abode, and place ourselves in his hands. If he sells anything we do not approve of we expect him to change it; and if he offends seriously we cease to buy from him. Supposing our tradesman, as frequently happens, to be a man who has been in business a long time, who has perhaps inherited it from his father, he will take good care not to sell us bad materials, or if by accident he does so, will put the matter right immediately he knows of it. I maintain, Sir, that this simple self-acting arrangement is quite sufficient protection for the ordinary transactions in electric lighting work, provided that the firm of contractors chosen are of sufficient standing and have a reputation to maintain. A firm of good standing would rather lose money than have a slur cast upon their work; and this is a far more efficient protection than could be provided by the employment of any consulting engineer, however eminent.

And the same difficulty exists here as in our domestic transactions. Who shall a buyer get to advise him? If he employs the eminent men who stand at the head of the profession, his consulting bill will add very much to the cost of his installation, unless it be a very large one; and, in addition, the actual cost of his installation will probably be higher than it otherwise would have been from the fact that it *may* happen that the eminent man whom he consults has not had much practical experience in the special class of work upon which he is called upon to advise, and therefore almost necessarily specifies more expensive materials than are really required, or than a practical man, with an intimate acquaintance with that class of work, would use successfully.

And if he does not employ the eminent men who have won their name, how can he know that the man he employs knows the work he is called upon to advise on, or that he will not be making experience at his expense? And if any mistakes are made, in place of the contractor paying for them, as he would do under the first arrangement, it is the employer, the user, who will have to pay.

But there is a third plan which is often adopted. Owners and managers in some cases wish to have all the advantages of both systems without the expense. They wish to have the advantage of the competition between rival contractors; but they do not wish to pay an expert to advise them, and to see that the work is properly carried out. They ask everyone whose name they have heard to tender. Usually, if the contract is of any value, the tender is followed up by a call from the representatives of the firms who have tendered, and then the fun begins.

Messrs. A. B. and Co.'s man devotes nearly the whole of the time at his disposal to depreciating the work of everyone else that is in for the job, and if he should succeed in getting a hint that C. D. and Co.'s tender is looked upon rather favourably, he forthwith explains that C. D. and Co. are very nice people, very nice; but if there is one thing they do not understand it is electrical engineering, and if there is any particular branch of which they are hopelessly ignorant, it is the particular work for which tenders have been asked. Then he promises something over and above his tender, in the hope of securing the contract.

C. D. and Co.'s representative goes through exactly the same process, till in the end it is doubtful whether a firm will lose most by taking or leaving the contract, and it is almost a toss up whether the buyer has made a good bargain or a bad one. If the firm he has finally selected, after the wire-drawing process above described, is one of those who have a reputation to lose, and means to support it, he is all right; but if he has chosen, say, a company that winds up a few weeks or a few months after, what security has he that he has got what he wanted or what he intended to buy?

With regard to public tenders the experience of my firm has been rather unfortunate. I will give two instances. We tendered for a contract for which a very eminent engineer had drawn the specification, and which was such as might be expected from a man of his knowledge and experience. We did not get the contract, it went to a firm that no one had ever heard of before, and it was whispered that the reason why the contract went there was because that firm would use a particular form of apparatus in which the engineer was interested. Whether this be true or not—I merely give the whisper for what it is worth—no one will deny that such a thing would be possible in certain cases. Consulting engineers are but human, and would naturally view with favour apparatus in which they have had a finger.

In the other case we were second, our tender being rather less than the bulk of the other tenders, and the one that was successful being considerably below any of us. The company that secured the contract did not live to complete it; but no fresh tenders were asked for, nor, though by the rules under which the failing company's tender had been accepted it should then have fallen to us, were we even communicated with. Under the circumstances of these and other tenders we considered we should do wisely in saving the money we should be obliged to spend in these competitions for the purpose of developing sound business. I think the above will show that the matter is by no means so cut and dried as Mr. Mountain's experience has led him to imagine.—Yours, &c.,

SYDNEY F. WALKER.

PROGRESS OF ELECTRIC LIGHT IN SWITZERLAND.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A few days ago, at Engelberg, a valley under the Titlis mountain in Switzerland, I was present at the preliminary trial of an electric light installation, a brief notice of which may be of interest to your readers. There are now in Switzerland a considerable number of installations, in which the ample supplies of water coming from the heights are used as the motive power. The Engelberg installation is the newest of these, and is highly satisfactory.

The village of Engelberg is a straggling little place about a quarter of a mile in length, in the midst of a fertile valley, and surrounded with mountains and high hills. There are several hotels; and nearly at the two extremities of the village are two—the Engel and the Hotel Titlis—owned by the same proprietor, Herr E. Cattani. The larger of these, the Titlis, a very handsome and well-appointed hotel, is supplied with electric light throughout, and the gardens and front of the house are lighted with arc lights. An arc light is also placed opposite the entrance of the smaller Engel, though the lighting is not yet carried through the interior.

The engine house is at a distance of 160 metres from the Hotel Titlis, and the water is brought to the turbine from the hills above by means of 270 metres of wide iron pipe. The quantity of water supposed to be available at all times is 200 litres per second; and the available fall is 25 metres, which gives nearly 70 *force de cheval* (over 60 horse-power). The turbine used is a turbine Girard (horizontal shaft), capable of yielding from 45 to 50 *force de cheval*; and the arrangements for regulating the supply of water, &c., are admirably convenient, though I cannot attempt to describe them without drawings. The shaft of the turbine is clutched on to a long horizontal shaft, from which the present dynamo is driven; and it is proposed, should the water-power be found at all seasons to fulfil present expectations, to drive a second large dynamo,

Digitized by Google

which will light up the Hotel Engel, and supply also a neighbouring Pension.

The dynamo is a powerful and beautifully finished Schuckert machine, calculated, I believe, for 500 lights. At present 300 Siemens 101 and 102-volt incandescent lamps are being used in the hotel. There are also five arc lamps, about 1,000 candles each, placed in the grounds, and one near the entrance of the Engel.

The mains are very heavy copper wires, which are supported, between the engine house and hotels, on poles like telegraph poles, and throughout the interior of the Titlis the electric light arrangements are made with great simplicity and with excellent taste.

The installation is the work of Stirnemann and Weissenbach, of Zurich.—Yours, &c., J. T. BOTTOMLEY.

Grindelwald, Switzerland, June 18, 1887.

THE INTERMINABLE TERMINOLOGIST.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seduced by your paragraph on the subject of electromagnetic terminology last week, I turned to the article to which you so flatteringly referred in the hope of finding something that might be useful to a practical man; and I do not deny that in that article, as well as in the singular letter which follows it to-day, some valuable hints and promising terms are my reward, though they would have inspired greater confidence had they not been disfigured by personalities which are in very bad taste, and eccentricities of diction which are beneath the subject under treatment. Mr. Heaviside is a great scientist; he implicitly declares it when belittleing somebody whom apparently he cannot abide; and, indeed, you will remember he has virtually "sworn it." Probably nobody will contradict him; I certainly will not; but it naturally occurs to smaller men than he that as high science itself is at loggerheads about its own terminology, and that as even this ingenious coiner of phrases has not yet so much as satisfied himself, it behoves him to be merciful to those whom high science may have misled or failed to enlighten. Mr. Heaviside, in to day's letter—and not for the first time—contemptuously refers to those who have unfortunately misunderstood Clerk Maxwell. Yet Mr. Heaviside himself later on asserts (as I think somewhat impertinently) that "it was very much his own fault" if Maxwell is "still to be fully appreciated"—which appears to be Heavisidean English for "not yet quite understood." Well, if Maxwell's expositions are anything approaching Heaviside's in obscurity, no wonder. The very sentence, consisting only of three lines, in which the unfortunate person is trounced who "could not see the force of Maxwell's argument," &c., can be construed in at least three different and opposite ways, through the slipshod use of the word "because." Am I hypercritical? Well, then, cast your eyes further down Mr. Heaviside's remarkable letter. "Conductances are the proper things to use." What sort of *things* are conductances, and how do you *use* them? Again, "with condensers, on the other hand, permittances are most useful." Would condensers be any less useful without permittances, and why are permittances most useful with condensers on the other hand? Next, we are told that "should, however, we join in sequence, then elastances are the proper things." It is satisfactory to learn that elastances are "proper," even under the conditional "should, however, we join in sequence;" but one would like to be sure where the impropriety comes in supposing we do not join in sequence, and would the Lord Chamberlain interfere? In his concluding paragraph Mr. Heaviside lets fall one of those dark and oracular sayings with which his writings so painfully abound, "The most absolute of all ways of finding the inductance of a coil is with a tape." It would appear from this that there are several ways of finding inductance, some of which are absolute ways, while others are more absolute; but that the most absolute is "with a tape." Very well; but we want to know what is to be done with it when we have found the creature? Many of Mr. Heaviside's readers say "Hang it;" but in that case its resistivity would be more effectually overcome (probably without its permittance), and its attenuation more certainly insured, by employing a piece of string. But this is a distortion. To return to the point, Mr. Heaviside tells us that the term "mac" is quite euphonious and unobjectionable. If that be granted, so, too, is smack; and for any scientist who takes unwarrantable liberties with his readers, or who drags his personal feelings into public print, or makes *un-*"meaningful" perversions of the English language, smack is really the only absolutely proper thing to use.—Yours, &c.,

24th June, 1887. AMICUS.

[We think, of course, that this letter is really too bad; but our readers will agree with us that in another sense it is rather too good to be lost.—ED. *E.*]

SUMMER COURSES OF LECTURES AT THE CITY AND GUILDS OF LONDON INSTITUTION.

A course of evening lectures (from 8 to 9 p.m.) on "Methods of Determining the Fundamental Standards of Electrical Measurements," will be delivered by Mr. R. T. Glazebrook, F.R.S., at the Central Institution, Exhibition-road, on Monday, Tuesday, Thursday, and Friday next. On the afternoons of Tuesday and Friday there will also be practical demonstrations in the laboratories. The following is a syllabus of the course by Mr. Glazebrook:—

I.—*Preliminary.*—Definitions and explanation of terms ohm, ampere, volt, farad. Theoretical considerations connected with some fundamental measurements; the ballistic galvanometer. Measurement and comparison of coefficients of self and mutual induction.

II.—*The Ohm.*—Absolute measurement of resistance. General principles of various methods:—1. Method of the B. A. Committee. 2. Weber's method. 3. Kirchhoff's method. 4. Lorentz's method. 5. Other methods. Summary of results.

III.—*The Ampere and Volt Measurement of Current and Electromotive Force.*—Principles of various methods:—1. The Electrodynamometer. 2. Current weighing. 3. Kohlrausch's method. Standards of current and electromotive force; the silver voltameter; Clark's standard cell.

IV.—*The Farad.*—Measurement of capacity. 1. The ballistic galvanometer method. 2. Method with a tuning fork. Construction and comparison of standards.

The course of lectures on "Testing Dynamos and Motors," delivered by Prof. Ayrton in the spring, will be repeated during the fortnight from July 5th, and with the practical demonstrations will occupy from 10 a.m. to 4 p.m. daily.

FRIEDLAENDER'S PORTABLE LAMP.

A portable incandescent lamp and primary battery, devised by Herr Friedlaender, of Berlin, is illustrated in the accompanying figures. The box is made of ebony, measuring 7in. × 4in. × 4in.,

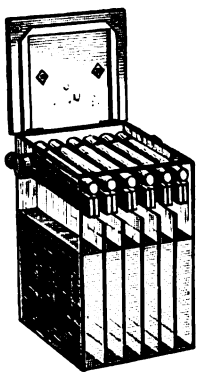

FIG. 2.

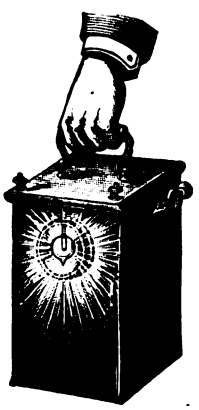

FIG. 1.

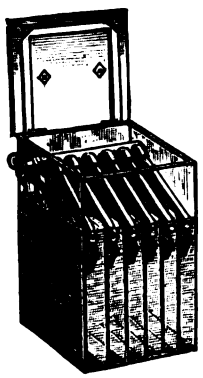

FIG. 3.

and is divided internally into six compartments, each of which contain a pair of zinc and carbon electrodes. The solution consists of a mixture of chloride of zinc and potassium bichromate, and has the advantage of entire freedom from either fumes or smell. With a lamp of 3 candle-power the solution is said to cost about 2d. per lamp hour. The plates are withdrawn from the cell by turning a knob at the side of the box, which lifts the electrodes out of the solution. Fig. 1 shows the external appearance of the cells, and Figs. 2 and 3 show the internal arrangements.

A HALF CENTURY OF TELEGRAPHY.

A few years back, when the craze for centennial celebrations was at its height, the suspicion arose that every great man must have flourished and every remarkable event must have occurred exactly one or more centuries ago. The promoters of these anniversaries experienced no difficulties in regard to dates. If the great man was not born in the particular year required he obligingly died in that year, or he did something that constituted an epoch or a landmark at the quite correct moment. Anyway, the centenary was celebrated with becoming enthusiasm, if not always with rigid respect to dates. In the case of the Jubilee which has just been—or, rather, is still being—celebrated throughout the length and breadth of the land no such historic doubts have crept in; and similarly with regard to the proposed Jubilee commemoration of the telegraph, foreshadowed in our last issue, the year and the day are as nearly coincident as the exigencies of public life will permit. The first electric telegraph of a really practical sort in this country was worked on the evening of July 25, 1837, and on Wednesday evening, July 27, 1887, its fiftieth birthday is to be appropriately celebrated. It was in the precincts of the metropolis—that is to say, between the Euston-square and Camden Town Stations—that the first electric telegram was flashed, and within a mile or two of that famous spot the living representatives of WHEATSTONE and COOKE will do honour to their memory, and proclaim with characteristic festivity the national pride in these fifty years' fruit of their labours.

In another column will be found the particulars of the proposed gathering, which it is understood will take the form of a banquet, where every Englishman of mark whose name is associated with the rise and progress of telegraphic enterprise we feel sure will be present. It will, we imagine, be an essentially English celebration; we do not mean exclusively so; that may be as it happens. But the occasion being one to mark the origin and rise of an English invention, the expansion of which has been largely, and in one branch of it wholly, due to British science, British capital, and British energy, the assembly ought to be British, and the demonstration a national one. Our claim to have invented the electric telegraph may be disputed both on the Continent of Europe and in America, but nobody has questioned the originality and utility of the system we propose to commemorate as our own, or denied the rapidity and vigour with which we have turned it to account in every corner of the world. It was in "a dingy little room, and by the light of a flaring dip candle" that the first words of the electric messenger over a distance of less than two miles were spelled out. Only fifty years have elapsed since that memorable night; and we see the whole world entwined in a network of myriads of miles of wire; and from the shabby little office in Euston square, the mind naturally turns to the gigantic proportions and splendid equipments of the English Central Telegraph Station to day. From the Holborn Restaurant, where the banquet is to be held, and where the electric light—itself an outcome of electrical research—will illuminate the proceedings, every word that is spoken might be transmitted to the other side of the Atlantic in less time than it took those two famous amateurs to make their first essay in telegraphy. That "tumultuous sensation" which WHEATSTONE experienced on hearing the click of the needles may in some degree be shared by us to-day; and if it be true that he felt "all the magnitude of the invention then proved to be practicable beyond cavil or dispute," the realisation of his wildest dreams has added fresh lustre to his name by attesting his boldness and foresight.

We have said that the claims of England for priority in the invention of the Telegraph may be disputed, and we have no need to assert them here. Prof. MORSE, who was working on a different line to attain the same end as that of WHEATSTONE and COOKE in this country, has claimed and received the distinction in his own person for America. But it is on record that MORSE publicly complained of "WHEATSTONE in England and STEINHEIL in Bavaria, who have their electric telegraphs, being afforded the means of bringing forward their methods, while to my invention of earlier date than theirs my country seems to show no favour." These words are at all events conclusive as regards the respective countries, whatever they may be as touching the individuals, whose relative merits are really never in question. What we as a country may fairly claim is that the first acceptance and application of electric telegraphy to practical uses was by England just fifty years ago. Perhaps, too, we have a further distinction in the GROVE and the DANIELL batteries, the latter of which contributed immensely to the success and development of the system, and, it is worth remembering at this time, dates from the same period—probably the same year—as the COOKE and WHEATSTONE telegraph; and both DANIELL and GROVE were Englishmen. We have therefore every reason to join in this Telegraph Jubilee without misgivings as to our title to do so, and although the celebration, like many others, owes its suggestion to the jubilant temper which pervades the breasts of

Digitized by Google

all true Britons just now, the telegraph has done so much for the social well-being, the material prosperity, and the stability of our empire, that this particular fiftieth anniversary could not with decency have been passed over in silence.

LITERATURE.

A Century of Electricity, by T. C. MENDENHALL. (London: Macmillan and Co.)

This is one of the Nature Series, of which some seventeen volumes have already appeared, treating scientific subjects in a popular manner, and most of them by Englishmen of scientific repute. Why the volume under review should have been chosen as the sole representative of electrical science is more than we can understand. It is American both in tone and treatment; and it fulfils none of the conditions required by English readers either from a scientific or a popular point of view. Yet it is here put upon the English market by an English firm expressly for English readers; whereas internal evidence conclusively proves that the author is conscious of none but an American audience. The fact of its reproduction by publishers so respectable as Macmillan and Co. would seem to imply that there is a great demand for electrical information in this country and nobody here competent to supply it. Or it may be that the book in question, or its author, has obtained such a great reputation in America as to warrant an English edition in preference to anything that could be had here. And this may very well be the case, for the book possesses considerable merit, both literary and constructive, of exactly that kind which finds favour in America, where broad notions of things in general are sought after rather than thorough and exact knowledge of any one subject in particular. But "A Century of Electricity" has no conceivable place in English scientific literature, and it fills no gap which could not have been as easily supplied by any hack writer provided with a biographical dictionary and a few elementary Electrical Text Books. As an historical sketch it may count for something, although its limitation to the century is quite arbitrary, and chiefly confined to the title page; whilst those portions which are devoted to description—in which the author really excels—are rendered valueless and illusory by the necessary restrictions of a small volume. Two hundred pages are far too few for any adequate treatment of the subjects he has taken in hand. And in this attempt he has not been assisted by the publishers, the illustrations being extremely meagre, and most of them as bad as they well could be. We have said that the book has some literary merits; and where the author sticks to his plain task he is really quite admirable. Not unfrequently, however, and more conspicuously in his opening and concluding chapters, he yields himself to the oratorical flights which are characteristic of the American platform, but in essaying which Mr. Mendenhall utterly and ludicrously fails. In short—and this is why we have noticed it at all—if that kind of book were wanted on this side of the Atlantic it could be done very much better by an English writer. Such as it is its attractive title may help to sell it; but unless we are greatly mistaken every reader who has bought it will consider himself sold.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XLII.

BY OLIVER HEAVISIDE.

Speed of the Current. Effect of resistance at the sending end of the line. Oscillatory establishment of the Steady State when both ends are short-circuited.

Although the speed of the current is not quite so fast as the square of the length of the line, yet, on the other hand, it is not quite so slow as the inverse square of the length, as a writer in a contemporary (*Electrical Review*, June 17, 1887, p. 569) assures us has been proved by recent researches. However, if we strike a sort of mean, not an arithmetric mean, nor yet a harmonic mean, but what we may call a scienticulistic mean (whatever *that* may mean), and make the speed of the current altogether independent of the length of the line, we shall probably come as near to the truth as the present state of electromagnetic science will allow us to go. But, apart from this, there is some *a priori* evidence to be submitted. Is it possible to conceive that the current, when it first sets out to go, say, to Edinburgh, *knows* where it is going, how long a journey it has to make, and where it has to stop, so that it can adjust its speed (scienticulistic speed) accordingly? Of course not; it is infinitely more probable that the current has no choice at all in the matter, that it goes just as fast as the laws of Nature, preordained from time immemorial, will let it; and if the circuit be so constructed that the conditions prevailing are constant, there is every reason to expect that the speed will be constant, whether the line be long or short. Q.E.D.

Now, a great and striking thing about the non-distortional system, whose elementary properties were discussed in the last section, is the distinct manner in which it brings the speed of the current into full view. Another and very important thing is this. When the leakage is not so adjusted as to remove the distortion altogether, solutions become difficult of interpretation, owing to the almost necessary employment of Fourier or other transcendental series to express results. But by a proper adjustment of the leakage so as to abolish the tailing, which is the cause of the mathematical difficulties, we are enabled to follow with ease the whole course of events, say, in the setting up of the final state, due to a steady impressed force, without laborious calculations. And, although the state of things supposed to exist in the non-distortional system is rather an ideal one, yet it allows us to obtain a very fair idea of what happens when there is distortion, *e.g.*, in the oscillatory establishment of the steady state in a well-insulated circuit.

When we speak of a charge travelling along a wire at speed v, it should be always remembered what this implies. There are two conductors, parallel to one another, and the positive charge on the one is accompanied by its complementary negative charge on the other (corrections due to parallel wires, &c., are ignored here). The two charges move together. More comprehensively, the whole electromagnetic field, of which the charges are a feature only, is moving along at speed v in the space between the wires, into which it also penetrates to a greater or less extent. In the non-distortional system this penetration is assumed to be perfect and instantaneous, so that the resistance and the inductance are strictly constants; and by the ratio R/L being made equal to K/S we make any isolated disturbance travel on without spreading out behind. In travelling it attenuates by loss of energy in the conductors and by leakage in such a way that if it attenuate from 1,000 to 900 in the first 50 kilometres, it will attenuate to 810 in the second, to 729 in the third, and so on; multiplying by 9/10 in every 50 kilometres.

In the last section was considered the uniquely simple case of a short-circuit at A, the beginning of the circuit, where any impressed force is placed, sending any shaped waves into the circuit, travelling undistorted, with uniform attenuation, and completely absorbed on arrival at the distant end B by a terminal resistance of amount Lv. Of course this complete absorption at B of all waves arriving there is independent of the nature of the terminal arrangements at A. But these will materially influence the magnitude of the waves leaving A. Keeping at present entirely to simple cases, if we insert a resistance Lv at A we can make a safe guess that the current will be just halved, because when there is a short-circuit there the line itself behaves just as if it were a resistance Lv. That is, the current at A is then e/Lv, however e may vary, provided there be a resistance Lv at B; or, which is equivalent, the circuit be continued indefinitely beyond B unchanged in its properties. This guess may be easily justified. That the current is zero when we insulate, or insert an infinite resistance at A, is also evident. In general, the insertion of a resistance R_0 at A causes the potential difference V_0 there due to an impressed force e to be

$$V_0 = eLv(R_0 + Lv)^{-1} \quad . \quad . \quad . \quad . \quad (15a)$$

and the current to match to be V_0/Lv. The transmission to the distant end, and the attenuation are as before.

Digitized by Google

But if the place of e be shifted along the circuit from A, interferences will result whenever the resistance at A has not the value Lv. Imagine e to be at distance x_1 from A. When put on, the result is to send a positive wave $\frac{1}{2}e$ to the right, and a negative wave $-\frac{1}{2}e$ to the left, both travelling at speed v, and attenuating similarly. Thus the circuit behaves towards e as a resistance $2Lv$, half to the right, half to the left. Now, when the negative wave arrives at A, if there be a resistance Lv there to absorb it, there will be no interference with the positive wave, which will go on to B and be absorbed there. The current at B will therefore be

$$C_B = \tfrac{1}{2}(e/Lv)\epsilon^{-R(t-x_1/v)} \quad . \quad . \quad . \quad (16d)$$

the value of e to be taken at a given moment being that at x_1 at the time $(t - x_1)/v$ earlier. But if there be a resistance at A of any other amount than Lv, there will be a reflected wave from A, which will run after the original positive wave, and so make every signal at B have a double or familiar following it after an interval of time $2x_1/v$, which is that required to go from x_1 to A, and back again. Now the closer the seat of e is shifted towards A, the more closely will the familiar follow the original positive wave; and when e is at A itself, they will be coincident in front. Now, the current at A corresponding to (16d) is

$$C_A = \tfrac{1}{2}(e/Lv)\epsilon^{-Rx_1/Lv}; \quad . \quad . \quad . \quad (17d)$$

and (as will be explained in the section on Reflections) the reflected wave is got by multiplying by ρ_0, where

$$\rho_0 = (R_0 - Lv)(R_0 + Lv)^{-1} \quad . \quad . \quad . \quad (18d)$$

Now make $x_1 = 0$ and we shall verify (15d), and, by the union of the positive and reflected also positive wave, show that V at x at time t due to $e = f(t)$, any function of t, at A is

$$V = f(t - x/v) \times Lv(R_0 + Lv)^{-1} \times \epsilon^{-Rx/Lv}, \quad . \quad (19d)$$

and the current there is V/Lv.

The most simple case after these of complete absorption at B, with complete absorption, or short-circuit, or any resistance at A, is perhaps that in which we short-circuit at both A and B. If a charge be then moving towards B it is wholly reflected with reversal of electrification. We must have $V = 0$ at B, and this requires every disturbance arising at B to be at once reversed and sent back again. The same thing happens at the short-circuit at A. Perhaps, however, the easiest way to follow events is to imagine the two charges, positive and negative, which always travel together, to pass through one another when they come to the short-circuit, so as to exchange wires. Thus one charge goes round and round the circuit one way, whilst the other, just opposite, goes round and round the other way. There is the usual attenuation. On this view of the matter, we may imagine the effect of a terminal resistance Lv to be simply to bring the charges to rest against friction. It need scarcely be said, however, that the day has gone by for any such fanciful explanation to be taken seriously.

Since the current in a negative wave (from B to A) is of the opposite sign to the electrification, there is no reversal of current by reflection at a short-circuit. As, therefore, the reflected wave is to be superimposed upon the incident wave, we see that the current is doubled at B from what it would be were the circuit to be continued beyond B, or the critical resistance Lv were inserted in place of the continuation.

The process of setting up the permanent state due to a steady e at A is now this. First the positive wave

$$V_1 = e.\epsilon^{-Rx/Lv}. \quad . \quad . \quad . \quad . \quad . \quad (20d)$$

if $x < vt$, which would be the complete solution were there no reflection at B. Now B is reached by V_1 in the time l/v, and the value of V_1 at B just on arrival is $e\rho$, if $\rho = \epsilon^{-Rl/Lv}$, which is the attenuation in the circuit. The reflected wave V_2 now begins. This is

$$V_2 = -e\rho^2.\epsilon^{Rx/Lv} \quad . \quad . \quad . \quad . \quad (21d)$$

which travels towards A at speed v. In the meantime the first wave V_1 is still going on, for the battery at A does not know what is going on at B. Thus, from $t = l/v$ to $t = 2l/v$ the state of the circuit is given by the sum of V_1 and V_2 so far as V_2 has reached, and by V_1 alone in the rest. On arrival of V_2 at A it is attenuated to $-e\rho^2$, and reflection then produces a positive wave

$$V_3 = e\rho^2\epsilon^{-Rx/Lv}, \quad . \quad . \quad . \quad . \quad . \quad (22d)$$

which is a copy of V_1, only smaller to the extent produced by the multiplication by ρ^2. This wave reaches B when $t = 3l/v$, and then there commences the reflected wave, V_4, given by

$$V_4 = -e\rho^4.\epsilon^{Rx/Lv}. \quad . \quad . \quad . \quad . \quad (23d)$$

going from B to A. This is a copy of V_2. And so on. Thus we have an infinite series of reflected waves, coming into existence one after the other; the state at any moment is expressed by the sum of the waves already existent; the final state is the sum of them all. Since the sizes of the positive waves form a geometrical series, and also those of the negative waves, they are easily summed. The positive waves V_1, V_3, &c., come to

$$e(1 - \rho^2)^{-1}\epsilon^{-R./Lv}. \quad . \quad . \quad . \quad . \quad (24d)$$

and the negative come to

$$-e\rho^2(1 - \rho^2)^{-1}\epsilon^{Rx/Lv}; \quad . \quad . \quad . \quad . \quad . \quad (25d)$$

so that the sum of (24d) and (25d) expresses the final V of the circuit. And, since the current is got by dividing by Lv in a positive wave and by $-Lv$ in a negative, the final current is the excess of (24d) over (25d) divided by Lv. Notice that whilst it is a process of settling down to the final state of electrification, it is a process of rising up to the final state of current. More strictly, whilst the potential difference at any spot oscillates about its final value, being alternately above and below it, the excursions getting smaller and smaller as time goes on, the current increments are all positive, though they get smaller and smaller. Now if the time l/v of a journey be exceedingly small, so that there may be thousands of journeys performed in getting up to say 99 per cent. of the final current, the current will appear to rise continuously, and the potential difference to have its final value from the first moment, which is in reality its mean value during the oscillatory period. This is the explanation I have before given of how it comes about that there is no sign of oscillation in any purely electromagnetic formulæ, such as are universally employed when such short circuits are in question that the current seems to have the same strength (when no leakage) everywhere. It is really rising by little jumps, and differently timed at different places, but the jumps are too small to be perceived, and too rapidly executed. And the electrification is really (unless the vibrations are specially checked) vibrating about its mean value at any spot, which is its final value, though this mean value is assumed (in electromagnetic formulæ) to be the actual value. But if the resistance in circuit be great, so that the final current is small, we have an oscillatory settling down of the current instead of a rise.

The solution (24d), (25d) is what we may at once get by considering the differential equation of the steady state and its solution to satisfy the terminal conditions. But our solution gives us the whole history of the establishment of this final state, and allows us to readily follow the oscillatory phenomenon into minute detail. When there is distortion there is difference in detail, which is then difficult to follow; but there is no substantial difference in the general results. We cannot make or break a circuit without a similar action in general. But we cannot expect to be able to simply formularise the results when the circuit is of an irregular type, *e.g.*, a laboratory circuit.

(To be continued.)

ADMIRALTY SPECIFICATION FOR ENGINES AND DYNAMOS.

Admiralty contracts for electric lighting *materiel* have hitherto been awarded within a comparatively narrow range of the best known firms, but we are sure that a large number of electrical engineers will be interested in the terms of a recent specification issued by the Director of Navy Contracts for the supply of engines and dynamos for ship lighting. We reproduce the specification verbatim, but in the schedules we have omitted the names of the firms to whose dynamos and

engines the contract was restricted. We see, however, no reason why the list should not be considerably extended :—

Specification

1. The engines are to be direct acting, of approved economical type, to be mounted and coupled to the dynamo, on a strong cast iron bed-plate, sufficiently stiff to fix to a 3in. fir deck without special wood bed, and planed on the under side.

2. The cylinders are to be of hard close grained cast iron, with gun-metal bushes and glands, with efficient sight feed lubricators, and with all necessary drain cocks, &c. Suitable means are to be fitted to enable the indicated horse-power of the engines to be ascertained. The cylinders and adjacent parts are to be cased with approved non-conducting material and mahogany or other approved covering. The driving shaft and connecting rods to be of steel, with bearings of gunmetal or phosphor bronze, or these lined with white metal. All moving parts to have large bearing surfaces, to be well balanced, to admit of ready adjustment, and fitted with efficient means of lubrication. All non-working parts are to have three coats of oil paint before leaving the contractor's premises.

3. The engine must be capable of working the dynamo, with the full load, the steam pressure, and at the speed stated in the schedule, when exhausting into the atmosphere, without knocking, undue vibration, or heating of bearing surfaces. When fitted on board the vessel the engine will be arranged to exhaust into a condenser as well as into the atmosphere, and it must work efficiently under these circumstances.

4. A governor capable of adjustment when running, or on other approved principle, is to be fitted to control the speed of engine. The variation of speed allowed by this governor when all the load is removed is not to exceed 5 per cent.

5. A pulley, 4in. in diameter and 1½in. wide, is to be fitted on the engine shaft in a suitable position for driving a revolution indicator.

6. The cylinders and all other parts subjected to steam pressure are to be tested by water to the pressure stated in the schedule before being painted or lagged, in the presence and to the satisfaction of the inspecting officer. The Admiralty are to be informed when the engines are ready for this test.

7. The dynamos are to be of the direct current type, and self-regulating. Each must be capable of generating and sustaining a steady current of the amperes stated in the schedule, with an E.M.F. of 80 volts at machine terminals when running at the speed stated in the schedule for the types of engines specified. A variation of more than 5 per cent. from the schedule speed will render them liable to rejection.

8. The dynamos are to be self-regulating for constant E.M.F. of 80 volts for all loads from 10 amperes to full load, at the specified speed, and capable of maintaining continuously the full current without sparking at the brushes, undue wear of the collector, or injurious heating of any part of the machine circuit in a temperature of 120 deg. Fahr. No part of the machines to be more than 20 deg. above the temperature of the atmosphere.

9. The armatures are to be well balanced and to run true, the whole to be well secured to the steel shafts, properly supported on long bearing surfaces, and efficiently lubricated.

10. The collector sections are to be of hard copper, insulated with mica ; they are not to be less than 1½in. deep, and not less than 80 in number for ring armatures and 50 in number for drum, and to have a brush working surface not less than that stated in the schedule, the whole to be well secured together, and to the armature coil and shaft.

11. The brushes are to be supported on a rocking bar capable of easy adjustment, three on each arm for machines of 400 amperes, two on one arm and three on the other for machines of 300 amperes, and two on each arm for the other sizes, each brush to be 2in. by ½in. by 7in., and to have a separate holder, spring adjustment with forward thrust, suitable hold-off catches, and to stand at an angle of about 50deg. to the surface of the collector at point of contact.

12. All working parts to be easily accessible for adjustment, examination, and repair.

13. The whole of the circuit of the dynamo to be of copper, with a conductivity of not less than 96 per cent., well insulated, the whole to be properly insulated from every part of the machine frame, and coated externally with varnish insoluble in water or oil, and of such a nature as not to become brittle from the heat of the copper, and the insulation of the machine circuit is to be such that during the official trial no spark can be obtained, by making intermittent contact with a piece of copper wire between the iron frame of the machine and either brush.

14. At Portsmouth Dockyard the engines and dynamos will be subject to a test of six hours continuous run with full load, and exhausting into the atmosphere, during which trial the consumption of water will be ascertained, and the apparatus will be required to satisfy this specification in every respect, without injury to any part of engines or dynamos. The engines must be capable of standing the removal of the whole load, by sudden break of the circuit, without injury.

15. Spare gear for the engines and dynamos is to be supplies for each set, in accordance with what may be considered necessary by the Admiralty, for the particular type of apparatus adopted. A list of such articles is to be submitted by the contractors for approval. The spare gear is to include the following items :—

Brushes complete for each dynamo	2 sets
Piston rings for cylinders, if so fitted	2 sets
Brasses or bushes for working parts	1 set
Springs for governor	1 set
Special spanners	1 set

The spare gear to be tried in place on the contractor's premises, in the presence and to the satisfaction of the inspecting officer.

16. Spare armatures for ships having two or more machines must be suitable for either machine.

17. The economy of working of the engines is of great importance. The contractors are to insert in the schedule consumption of water per hour per electrical horse-power of 746 watts at machine terminals they are prepared to guarantee on the official six hours' trial at Portsmouth. Should the actual consumption per hour, on this trial, as reported by the dockyard officers, exceed that guaranteed, a deduction from contract price will be made for each excess of 1lb. per electrical horse-power per hour, according to the following scale :—

400 ampere machines	£16
300	12
200	8
100	4

Should the consumption of water per electrical horse-power per hour exceed that guaranteed by 10lb., the engine and dynamo may, at the option of the Admiralty, be totally rejected.

Digitized by Google

18. Special care is to be taken in designing the apparatus, so that the weight and space required for it, and for removal and access to all parts, is reduced to a minimum.

19. The contractors will be held responsible for the efficiency of the whole of the apparatus supplied till the expiration of a period of 12 months from the date of receipt, and any parts which during that period may be found defective or showing symptoms of weakness, owing to faulty design, materials, or workmanship, must be removed, and others substituted for them, by the contractors at their own expense, or the defects may, at the option of the Admiralty, be made good at the dockyard, and the cost charged against the contractors. The cost of making good any defects which may arise from fair wear and tear, or from improper management by the staff of the ship, will be borne by the Admiralty.

20. A tracing on cloth, showing clearly, in full detail, the arrangement of the engine and dynamo, and a copy of instructions for the care and management of the apparatus, are to be supplied with each machine, if required, also one copy of each for the Admiralty Office.

The following is a list of the ships for which the machines were required:—"Victoria," "Sans Pareil," "Australia," "Galatea." "Narcissus," "Ajax," "Serpent," "Racoon," "Thames," "Northampton," "Curaçoa," "Iris," "Emerald," "Boadicea," "Canada," "Carysfort," "Superb," "Swiftsure," and "Volage."

THE JUBILEE OF THE TELEGRAPH.

A numerously attended meeting of the gentlemen who have been appointed a general committee to make arrangements for celebrating the fiftieth anniversary of the construction of the first practical electric telegraph in England was held on Tuesday, at the offices of the Society of Telegraph-Engineers, 4, The Sanctuary, Westminster.

On the motion of Prof. HUGHES, F.R.S., Mr. W. H. Preece, F.R.S., of the Telegraph Department of the Post Office, was voted to the chair.

Mr. WEBB (the secretary) having read the notice convening the meeting,

The CHAIRMAN said that the first practical test of the telegraph was made in England on July 25th, 1837, by Messrs. Cooke and Wheatstone on the railway between Euston and Camden, and it was owing to the success that attended that experiment that they succeeded in getting the assistance of Stephenson, George Parker, Brunel, and of other well known men of that day to help them in the development of the idea. From that small beginning they had seen how the telegraph had spread like a network all over the face of the world, and how in England, where the first step was taken in its practical application, they had succeeded up to the present in keeping well in the van of the progressive development of the science. It therefore seemed a fitting thing that such an important event among the many other notable achievements that had been made during the long reign of Her Majesty, which had just been celebrated, should be in some way commemorated, and that those who had been instrumental in bringing telegraphy to its present position of importance in the world should meet together, and take the opportunity of collecting around them many who were still living, although they were not now seen amongst them, but whose names were well known in connection with telegraphy in the earlier years of its history, for the purpose of publicly celebrating the occasion. It happened that the proper day on which they ought to celebrate what he would call their Jubilee was July 25th, but there were several good reasons why it was extremely difficult to fix upon that date. In the first place, Monday was a day on which their legislators were very busy in the House over the way, and it would be very difficult for the committee to get any members of Parliament to attend on that day. Again, it was quite impossible on a Government night like Monday to get the Postmaster-General to take the chair, and as that gentleman was at the present time the representative of the principal telegraph interest of England, it was thought proper that he should be invited to preside on the occasion. On July 23rd, on the other hand, there was going to be a great Naval Review at Spithead, and as a good many of their friends who would like to be there would not get back until Monday afternoon, it was thought that Wednesday, July 27th, would meet the wishes and convenience of everybody. After consultation with Mr. Alabaster and Mr. Biggs, and a few others, they agreed not to raise the question of the best day but to fix upon the 27th July. The first thing that they had to do, therefore, was to decide that it was desirable that a dinner should be held on the 27th of July, to celebrate the Jubilee of the electric telegraphs. He concluded by formally moving a resolution to that effect, which having been seconded by Mr. Willoughby Smith, was carried unanimously.

Resolutions were subsequently passed, after a good deal of discussion, fixing the price of the ticket to the dinner at 10s., providing for a guarantee fund to meet contingent expenses, and deciding upon the Holborn Restaurant as the place of reunion.

The following gentlemen were afterwards appointed an executive committee to make the final arrangements for the dinner:—Prof. Hughes, Messrs. Graves, Stroh, Spagnoletti, Siemens, Patey, and Preece.

Mr. F. H. Webb was appointed acting secretary, and Messrs. H. Alabaster and C. H. W. Biggs were elected honorary secretaries.

It was further resolved to entrust the musical arrangements to the executive of the Electro-Harmonic Society.

It may be mentioned for the convenience of those members of the general committee who were not present on Tuesday that the next meeting will be held, at the same hour and place, on Tuesday, July 4th, when it is expected that the sub-committee will present a final report of the arrangements.

Subjoined we give a list of the names of the

General Committee.—Sir Frederick Abel, C.B., D.C.L., F.R.S.; Prof. W. G. Adams, F.R.S; H. Alabaster, Sir James Anderson, W. S. Andrews, W. T. Ansell, F.R.G.S.; F. E. Baines, C.B.; Major C. F. C. Beresford, R.E.; C. H. W. Biggs, F.C.S.; John Bordeaux, Sir C. T. Bright, M.Inst.C.E., F.R.A.S.; E. B. Bright, M.Inst.C.E.; G. L. Bristow, Sir S. Canning, C.E.; W. Lant Carpenter, B.A., B.Sc.; G. von Chauvin, S. M. Clare, Edwin Clark, Latimer Clark, M.Inst.C.E.; T. R. Crampton, M.Inst.C.E; R. E. Crompton, William Crookes, F.R.S.; R. S. Culley, Charles Curtoys, F. Despointes, H. G. Erichsen, J. A. Fleming, M.A., D.Sc.; H. C. Fischer, Prof. G. Forbes, M.A., F.R.S.S. (L. and E.); John Fuller, F. E. Gatehouse, Charles Gerhardi, Dr. J. H. Gladstone, F.R.S.; Edward Graves, Robert K. Gray, Matthew K. Gray, J. H. Greener, Dr. J. Hopkinson, M.A., F.R.S.; Prof. D. E. Hughes, F.R.S; Gisbert Kapp, A.M.Inst.C.E.; H. R. Kempe, A.M.Inst.C.E.; J. C. Lamb, Louis Loeffler, Sir Henry Mance, C.I.E., M.Inst.C.E.; Admiral Mayne, R.C., C.B.; G. G. Newman, Jos. Oppenheimer, C. H. D. Patey, C.B.; W. H. Preece, F.R.S.; J. Radcliffe, Henry Sach, Sir David Salomons, Bart, M.A.; Alexander Siemens, Willoughby Smith, C. E. Spagnoletti, M.Inst.C.E.; Augustus Stroh, Prof. S. P. Thompson, D.Sc., B.A.; Sir William Thomson, LL.D., D.C.L., F.R.S.S. (L. and E.); H. P. Vernon, John Walsh, Henry Weaver, Major-General Webber, C.E, C.B. (late R.E.); L. Wells, T. H. Wells, E. T. Truman Wood.

H. Alabaster and C. H. W. Biggs, hon. secretaries; F. H. Webb, secretary.

The executive committee met on Wednesday, when the hon. secretary reported that the largest room—the Venetian room—at the Holborn Restaurant had been secured for the dinner, also two large rooms as reception rooms. It was arranged by the committee that circulars should be sent to all members and associates of the Society of Telegraph-Engineers, and to all gentlemen whose names and addresses could be obtained who had either in the past or present been connected with telegraphic operations. Other executive business was transacted.

[We may mention that the guarantee fund is open, and that the secretaries will be glad to receive additional names and contributions.]

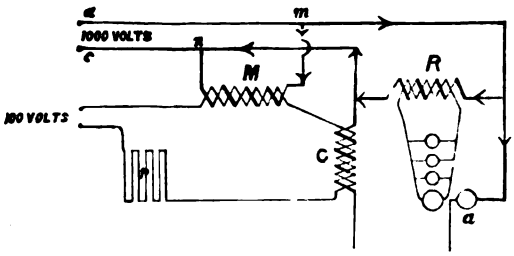
LIGHTING WITH TRANSFORMERS AT ANTWERP.

Our Brussels correspondent writes as follows:—

"Some interesting experiments in electric lighting with transformers were carried out on the 18th inst. by the Société Industrielle d'Electricité, of Brussels, in the presence of a large number of notabilities. The guests were received by M. Beckmann, member of the Chamber of Representatives, and M. Dewalque, Professor at the Louvain University, both of them 'administrators' (directors) of the company, and M. Goffin, chief engineer, conducted the trials. These were in connection with a new central station to be established at Berchem-lez-Anvers, with transformers used under special and unusual conditions. This is the essential point of the system which is already working experimentally, but with success, in the shops of the Industrielle. The transformer adopted by this company maintains 500 lamps 5 kilometres (3 miles) off with a 4 millimetre wire. At Berchem the engines will be placed at a distance of 2½ kilometres (1½ mile) from the transformers. The main current of 1,000 volts is conducted from the dynamo to the exit poles of the *ensemble* of

Digitized by Google

apparatus composing the system, passing through an amperemeter on one side, and on the other through an induction coil C (see diagram of installation at works), formed by a double winding round an iron core. Immediately after leaving the poles of the dynamo the main current is shunted at *m n* to a transformer M, which the inventors call a *Magnetiser* because it serves to produce a secondary current for exciting the machine. This current, issuing from the magnetiser, goes to the poles of the machine, entering the coil C at both ends, thus forming a *Compensator*. This double arrangement on the outside constitutes a hyper-compounding of the arrangement, and it is thus that so perfect an accordance is obtained of expenditure of current with the number of lamps in use. The exciting current also passes through an artificial resistance, *r*, variable by hand, which serves to regulate the initial intensity of the excitation, and to bring the machine to its normal *régime*. R is a small transformer, also in shunt circuit, which constitutes the *Reducer*, the office of which is to reduce the tension of the current, so that it may be measured by the ordinary appliances. It also affords the means of maintaining the lamps at the central station, which are in a secondary circuit. The other poles have shunt circuits to the three transformers at the end of the distance to be traversed, viz, at Berchem. Be it added that, by a similar arrange-



ment, another commune or district, near Antwerp, may be electrically lighted for 2¼ centimes per lamp per hour, while gas costs 3½ centimes per burner per hour."

CHUBB'S ELECTRIC SAFE ALARM.

We illustrate below a new safe alarm designed by Mr. N. G. Thompson, of Messrs. Thompson, Dowsing and Rew, for Messrs. Chubb and Co., the well-known safe manufacturers.

We are informed that Messrs Chubb and Co. had tried a somewhat similar arrangement some years previously, but it was found impracticable on account of the difficulty of obtaining a constant cell not requiring too much attention.

Mr. Thompson has, however, succeeded in minimising these objections by the introduction of his own battery, and by employing a galvanometer contact, the sensitive action of which has enabled him to employ a comparatively feeble current.

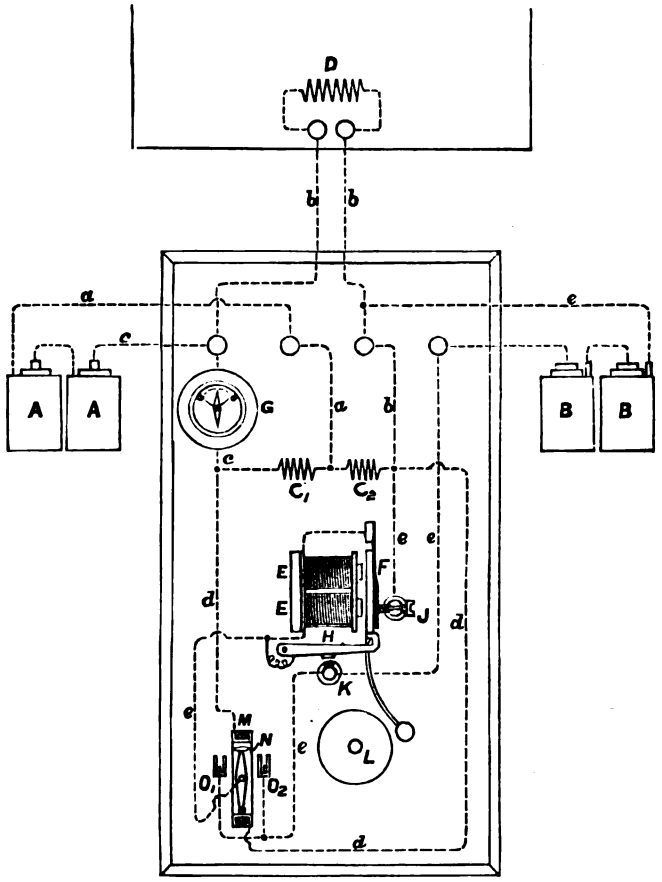
The object obtained by this alarm is that any two ordinary bell wires can be led from the safe to a bell-ringing apparatus in another part of the building, and although the wires may be exposed and secured to open terminals outside the safe it is impossible for anybody to tamper with them, either by cutting or bridging, without causing the bell to ring.

A series of contacts are also placed in and throughout the safe on the same circuit, so that if either the escutcheon be lifted, the door opened, or the safe removed, contact is immediately broken and the bell set in action. On reference to the drawing it will be seen that there are two batteries, the cells, A A, of the one being of the constant type referred to, and will maintain an even current for months, without any other attention than occasionally replacing the water and zincs in the inner vessels, whilst B B are ordinary Leclanché; CC_2 are two equal resistances, and G is a galvanometer, having a resistance approximating to that shown at D in the safe.

This galvanometer has a view needle, which shows when the current is on, and also indicates the condition of the constant battery. E E are ordinary bell magnets actuating the armature F, which supports or releases as the case may be the contact arm H. J and K are contact pillars, and L is a bell gong. M is also a galvanometer, having a vertically balanced needle, N, with platinum needle points attached to its upper end, the lower end being slightly weighted, and O_1 O_2 are mercury cups through which the needle points can dip, and so make contact. The contacts in the safe, the main switch, and the lever for replacing the arm H are not shown in the drawing. Prior to any disturbance in the safe circuit the current from the cells A A passes down the lead *a a*, and then divides through the two resistances C_1 C_2, and is conducted by circuit *b b* through the resistance D, and also by circuit *c c* through the galvanometer G back to the cells. The galvanometer M being in balance no current passes round it.

If, however, the circuit *b b* leading to the safe be cut, the galvanometer M will be thrown out of balance, and a current will be established through the circuit *d d*, which will cause the contact needle N to deflect, and so establish a momentary circuit by eKeJe on the bell battery, the consequent action being that the armature F is pulled towards the magnets E F, and releases the contact arm H, which short circuits the galvanometer M, and firmly establishes the bell circuit. The bell will then continue to ring till the arm H is again varied, the galvanometer needle having returned to its vertical position by reason of its weight.

If, however, the circuit *b b* leading to the safe is bridged at the terminals on the safe, or in fact anywhere, the galvanometer M is



again deflected, and the same results follow, by reason this time of a current passing in the opposite direction through the circuit *d d*.

A NEW MAKE-AND-BREAK TELEPHONE TRANSMITTER.*

What the action in the telephone transmitter is has been the subject not only of much controversy but of arduous research. The theory of Prof. Bell that articulate speech can only be transmitted by variations of a continuous current, *i.e.*, an undulatory current, has from the beginning been denied, and a number of forms of apparatus have been constructed to prove the contrary. These "make-and-break" telephones, as they are called, have, as a rule, been so constituted that the makes and breaks are effected by the action of the sound waves impinging against a diaphragm to which the contact point is attached.

In order to make the action of the make and break entirely clear Mr. Stephen D. Field and Mr. Rudolph Eickemeyer have recently constructed a telephone transmitter in which the transmitting points are not in contact when the instrument is at rest.

The instrument is, in fact, an automatic circuit breaker, which automatically makes and breaks an electric circuit with a rapidity too great for its effects to be appreciated by the ear. A diaphragm is then arranged so that sound waves projected against the same are caused to bridge over more or less of these makes and breaks of the circuit in proportion to the rapidity with which the sound waves succeed each other.

The instrument, which is decidedly novel in many respects, is shown in Fig. 1. The diaphragm M supports a platinum contact point G. The mouthpiece Z is attached to the front of the instrument, and sound waves entering strike against the diaphragm M

* From the *Electrical World* of New York.

Digitized by Google

carrying the contact G. The contact point E is cushioned against a soft rubber cushion, *e*, which is of spherical shape, and is provided with a perforation, through which the fine wire C passes for attachment to the contact piece. The wire also passes through a hollow screw, *j*, which is set into the head of the telephone, and an adjusting screw O regulates the tension upon the rubber cushion through the wire C. The apparatus also comprises the usual battery B and induction coil H, together with a switch.

It will be seen that the circuit of battery B passes normally through the insulated metallic frame J of the telephone and the wire C to the contact E. It will also be observed that there is a short circuit by way of wire I between the contact point G and the frame J. The tension of the wire C is normally sufficient to separate the points E and G. When, however, the switch A is closed, and the cuirent from battery B passes over wire C, the latter will heat and expand, and allow the points to come into contact. The current will thus be shunted around the wire C through a path of approximately no resistance, and as a result, the fine wire, becoming cool, will contract and separate the contact points. The apparatus thus becomes a circuit breaker, working with almost inconceivable rapidity so long as the current from the battery B continues to circulate. The makes and breaks are so rapid as to pass beyond the limit of receptivity of the ear.

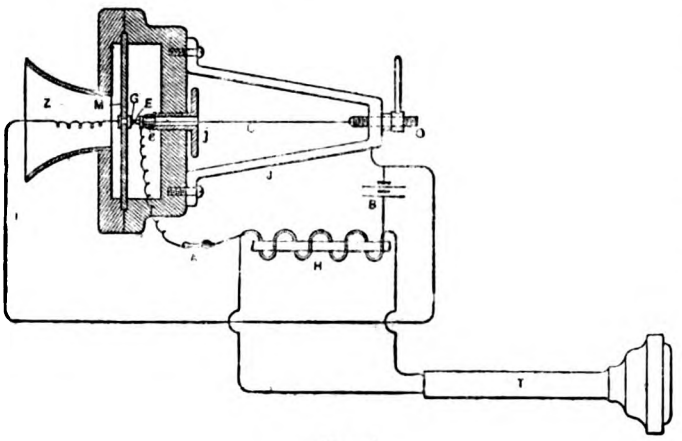


FIG. 1.

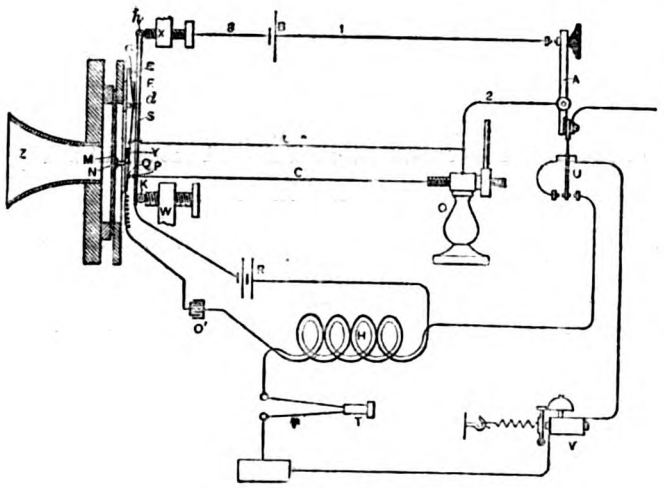

FIG. 2.

Now, it is evident that sound waves striking upon the diaphragm M will alter the relative positions of the points E and G, tending to prolong their respective contacts. These prolonged contacts will produce effects which are audible, and if they follow each other in the proper sequence articulate speech will be transmitted and reproduced in the receiving instrument.

The object of the cushion *e* is to render the apparatus more sensitive as regards the action of the wire C in response to successive heating and cooling.

The cushion forms a sufficiently rigid home for the contact G, and is at the same time sufficiently yielding to respond quickly to the expansion and contraction of the wire C. The diaphragm M is an insulating diaphragm of wood.

In another form of apparatus embodying the same principle, and shown in Fig. 2, the points E and G are supported respectively upon levers S and F, the former being pivoted at *h* and the latter at *d*. The relations of the two levers can be adjusted by means of the screws W and X, the former of which bears against the lever S at one end and the latter against the rubber spring K, which is located between the other end of the lever and the screw W. The circuit of battery B in this apparatus, when the key A is closed, passes by way of wire 1, key A, wire 2, adjusting screw O, and fine wire C to the lever S and back to the battery by way of the screw X and the wire 3. The closing of the key will therefore cause the current of battery B to pass through the wire C, thus heating and causing it to expand. The wire will accordingly be lengthened, and the tension upon the lever S will be relaxed, allowing it to move towards the lever F by reason of the pressure exercised upon it by the rubber spring E. If this lever movement continues far enough, the points E and G are brought into contact, closing a short circuit around the wire C. The short-circuiting of the wire C will cause it to cool and contract, and thereby break the contact between the points E and G, whereupon the above operation will be repeated automatically as long as the key A is kept closed. A sound wave striking upon the diaphragm M will therefore tend to cause a separation of the contacts E, G, and to prolong the expansion of the wire C. Now, the lever S carries besides the contact point E a point, P, which is located exactly opposite a similar point, Q, on the lever F. The action by which the movements of the diaphragm tend to prolong the expansion of the wire C will accordingly tend also to prolong the contacts of the points P and Q when the latter is moved towards it by a movement of the diaphragm due to the effects of a sound wave. The condenser O' is included in the battery circuit to prevent sparking.

By employing a thin diaphragm, and sealing up all the works in a heavy cast-iron box to cut off outside vibrations, the apparatus may easily be made to serve as a telephone repeater. The diaphragm is then arranged with an electro-magnet in proximity to it, the magnet being included in the line over which impulses are being sent.

The idea embodied in the invention is that the fine wire C, with its connected contact point, forms an automatic circuit-breaker whose makes and breaks produce no audible effects upon the circuit, by reason of the great rapidity with which they follow each other. That is to say, the normal vibrations of the circuit-breaker, considered with respect to their capacity to reproduce sounds, are neutral or inharmonious. That which reduces them to harmony and enables them to reproduce sounds in a receiving instrument are the devices which bridge over or throw together more or fewer of the inharmonious vibrations and thus alter their natural sequence.

A FEW COMPARATIVE STATISTICS OF ELECTRIC RAILWAYS.*

BY T. COMMERFORD MARTIN.

It is not now my intention to present a paper on the general subject of electric railways. That I did at a meeting of the Institute held last December, when I was enabled to offer a few statistics on the electric railway as compared with horse, cable, and other methods of traction for street cars. I have found since then a great desire generally for information as to the status of electric roads in the United States and Europe. Street railway men, investors and others have wished to know whether such a thing as an electric road was really operating anywhere or not, and, if the lines were running, what the cost of construction and operation was. The tables I submit herewith are intended as an answer to those queries. It has been difficult to get at a common basis of estimate and statement. With regard to the European roads, I would say that I have been greatly indebted for the figures to a most admirable and exhaustive paper, read a few weeks ago by Mr. Reckenzaun before the London Society of Arts. In Europe, as here, various systems of transmitting the current and of connecting up the motor with the car axles and wheels are in use, and as yet no determination as to the best method seems to have been reached.

Respecting the figures for this country, I would say that they are necessarily very much in the shape of an estimate as to the number of passengers; though, by allowing each car only 50,000 passengers a year—merely 150 a day—my calculations come out as rather low. The facts may be summed up by saying that in Europe the electric railways are now carrying passengers at the rate of 3,000,000 annually. In America they are carrying at the rate of over 3,500,000, and when the roads now building are finished—to say nothing of the scores for which contracts are being made—the number carried will be at least 7,000,000 annually. When the roads at the places I enumerate in the tabular foot-notes all go into operation, the number will be easily quadrupled. As to cost, I would remark that in every instance yet brought to notice, electricity has spelled economy. I saw recently some authentic and

extremely elaborate statistics for 1879 of street railways and their cost in New York and Brooklyn. They were taken from the various official reports. The showing for the total cost of operation per car ranged between $8 and $10 per day at that time. The saving on that with electricity is, according to circumstances, at least 25 to 40 per cent. with heavy traffic.

A PRACTICAL TEST OF STORAGE BATTERIES FOR TRAMWAYS.

In a paper read before the Electrotechnischer Verein, at Berlin, Herr J. L. Huber, the engineer of the Hamburg street railway, gives some very interesting details regarding the cost and operation of storage batteries on street railway lines. The system employed by Herr Huber is the Julien, in which the storage batteries are carried by the car.

In order to obtain reliable results, experiments were undertaken on a specially difficult line, both as regards curves and grades, and which, in addition, crossed much frequented streets, so that all the difficulties met with in railroad traffic in populous cities were encountered. The road extends from the Rathhausmarkt, in Hamburg, to the Berthastrasse, Barmbeck, over the Mühlendamm, on which line grades of 30 per cent. are encountered.

Herr Huber states, regarding the durability of the E.P.S. storage battery employed, that deterioration takes place only in the positive plates; and this is the more pronounced the greater and more frequent the normal strength of current for which the plates are designed is exceeded. With a well-regulated management—that is, by an arrangement of storage batteries and car, such that with the heaviest grades and loads no abnormal current is drawn from the battery—the wearing out of the positive plates amounts to from 2 to 3 per cent., or, in round numbers, $2\frac{1}{2}$ per cent. for 1,000 kilometres travelled. If, in addition, the traffic be so arranged that with every charge of the accumulators only 50 per cent. of the distance is travelled which could be travelled with new plates, then a wearing out of the plates amounting to 50 per cent. is permissible—that is to say, that over 20,000 kilometres (12,500 miles) can be run before renewal becomes necessary. A car which, including passenger and storage batteries, weighs 7,000 kilogrammes (about 7 tons), and which is to ascend grades of 30 per cent., such as occur on the Hamburgh line, requires 800 kilogrammes of active material in the positive plates, and its renewal, including the cleaning of the grids, which can be used over again, as they are not oxidizable, costs 1s. per kilogramme (2·2lb.)—that is, 4 pfennigs ($\frac{1}{2}$d.) per kilometre run. That would be 0·8d. per car mile for renewal of plates.

Under the same conditions the motive power required is $\frac{3}{4}$ horse-power hour per kilometre ($\frac{3}{8}$ mile) run. The cost for attendance, oil, maintenance, &c., for one-horse power hour is 1d.; consequently this cost per car kilometre is $\frac{3}{4}$d. To the above items must be added the maintenance, oil, &c., for the motor on the cars, which amounts to $\frac{1}{4}$d., and contingencies run up to an additional $\frac{1}{4}$d. The total cost, therefore, with the conditions given amounts to $1\frac{1}{4}$d. per car kilometre (2·8d. per car mile) or $\frac{1}{4}$d. per tonne kilometre ($\frac{1}{4}$d. per ton mile).

Comparing the cost of electrical traffic with that of horses, Herr Huber states that to operate the usual one-horse car, which, including driver and conductor, carries 26 persons, 7 horses are required on the same line for one day of 100 kilometres run. So that, as the electric car carries 31 persons, $8\frac{31}{100}$ horses would be necessary. The cost of maintenance for one horse during the last year, according to the *Jahresbericht der Strassen-Eisenbahn-Gesellschaft*, Hamburgh, amounted to 1·96s. per day per horse; so that the cost per car kilometre amounts to 2d. (3·2d. per car mile). It follows, therefore, that even to-day electricity is more economical than horseflesh, and the cost of the former can be considerably reduced by improvements.

The results of experiments show that 88 per cent. of the energy stored in the accumulators can be drawn out, and Herr Huber only counts upon 80 per cent. for safety; that is to say, that of the electrical energy delivered by the dynamos 20 per cent. is lost by the use of accumulators, and this is independent of the length of the line and the power required upon the same, such as the overcoming of grades, &c. It is to be remarked, also, that for the electric traffic such as exists in Hamburg, any car driver can be employed and no trained men are necessary, as is the case with locomotives, so that the expense of trained hands is avoided.

The above are the results of experiments which were carried out from the end of May to the end of December of last year, with a public passenger car, and the distance travelled amounted to 12,000 kilometres (about 7,500 miles). As these experiments were undertaken in public traffic on an ordinary horse road made specially difficult by its grades, and not upon a road specially constructed for the purpose, Herr Huber is of opinion that the life and power of competition with other systems of the storage battery is definitely assured.

THE MEASUREMENT OF SELF-INDUCTION, MUTUAL INDUCTION, AND CAPACITY.

BY W. E. SUMPNER, B.SC.

(Continued from page 150.)

Maxwell's absolute method being thus equally applicable to the measurement of self-induction, mutual induction, and capacity, it seemed very probable that any method of measuring either of these quantities would suggest methods of measuring the remaining two. For that purpose I have traced out an analogy, which is represented in the figures. The first twelve figures show the result of the analysis of Maxwell's methods. The next six figures (13—18) represent the result of an analysis of Fleeming Jenkin's method of determining the capacity of a condenser. Figs. 13, 14, and 15 represent analogous methods of determining the self-induction of a coil, the mutual induction of two coils, and the capacity of a condenser. The coil or condenser is charged by making the battery connection, and discharged through the galvanometer. In the case of mutual induction the alteration of the current in the battery circuit causes a quantity of electricity to rush through the galvanometer, which is a measure of the product of the change of current and the mutual induction. In each case it is necessary to determine the meaning of the swing of the galvanometer, and to eliminate the unknown electromotive force of the battery. This can be done by the same method in each case.

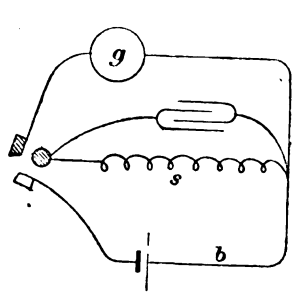

Fig 13.

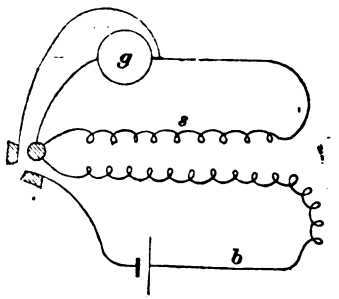

Fig 14.

If, however, the battery and galvanometer connections are made and broken periodically the effects are accumulated, and the galvanometer will give a steady deflection, which, on being compared with the deflection given by the same galvanometer and battery when a known resistance is in circuit, will render it possible to determine the required coefficient directly in terms of the resistances used, the ratio of two deflections, and the period of the commutator cycle. A ballistic galvanometer may therefore be dispensed with. In the method indicated by Fig. 13 a short interval may be allowed to occur between breaking the battery connection and making the galvanometer connection, provided a condenser be used. It is, however, better to dispense with a condenser, and allow a short time to elapse between making one connection and breaking the other, for when the coil having self-induction is suddenly isolated its electro-kinetic momentum will cause the potential difference of the condenser shunted to it to alter almost instantly to many times its original value. In either case, however, a correction will have to be applied to the formula. In the method of Fig. 15 an interval may with advantage be allowed to occur between the breaking of one connection and the making of the other. In the method of Fig. 14 it is advantageous to make the connection which short-circuits the galvanometer before breaking the battery connection.

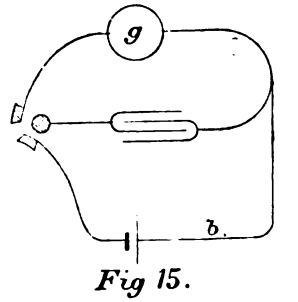

Fig 15.

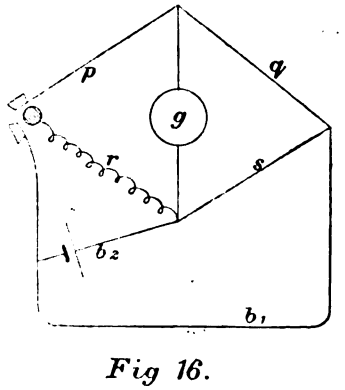

Fig 16.

As, however, the effect of accumulating all the impulses in one direction is, as far as galvanometers are concerned, to produce steady currents, it is easy to develop these methods into null methods. We have only to shunt part of the battery current continuously through the galvanometer. Figs. 16, 17, and 18 show the result. The battery has to be placed differently in Figs. 16 and 18, because a condenser discharges in the opposite way to that of a coil having self induction. A particular case of Fig. 18 is when the resistance R shunting the condenser is made infinite. If we suppose the self-induction of the wire R to increase, and the capacity of the condenser to diminish, the effect on the galvanometer due to the induction diminishes through zero till, in the limit when the capacity of the condenser is nothing, we have merely the case of Fig. 16. The remarks

Digitized by Google

about the commutators of Figs. 13, 14, and 15 apply equally to those of Figs. 16, 17, and 18. In Fig. 17 it is seen that the commutator develops into that used by Profs Ayrton and Perry.

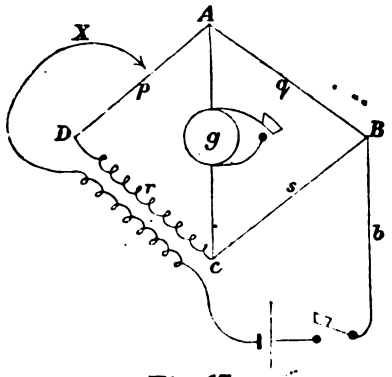

Fig 17.

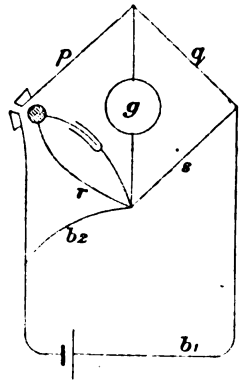

Fig 18.

In seeking the method of measuring mutual induction analogous to the methods of Figs. 16 and 18, it was found that the end X (Fig. 17) of the battery branch could be placed at any point on the bridge along A D C. Now, if the point X be connected with D, we have Maxwell's method; while, if it be connected with C, we have a simple deduction from Prof. Carey Foster's method when we accumulate, since, under these circumstances, it is easy to see that the condenser used by Prof. Carey Foster is needless. There is consequently a close relationship between all these methods, and no one of them is distinct.

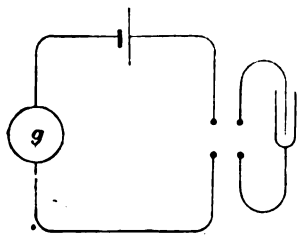

Fig 19.

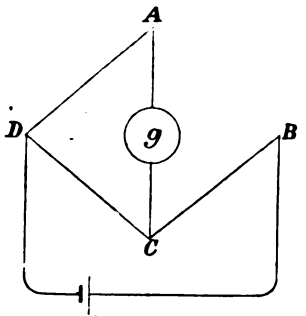

Fig 20.

Figs. 19—21 show methods for finding capacity and self-induction which are analogous with a method given by Maxwell (Vol. II., sec. 776). Fig. 20 represents a Wheatstone bridge in which one of the arms A B is absent, and this absent arm may be supplied by any one of those represented in Figs. 20a to 20f. Figs. 19 and 20a represent Maxwell's method of finding capacity (Vol. II., sec. 776)—a method to which he was led by the consideration that if the connections of a circuit with the terminals of a condenser were periodically interchanged, the effect of the capacity would be comparable with that of a resistance. The same analogy led to a method of finding self-induction described in the appendix of the paper of Profs. Ayrton and Perry, and represented in Figs. 20e and 21. The difference between the two cases consists in the fact that the more rapidly a condenser is commutated the less is its apparent resistance, while the reverse is the case with self-induction. In Fig. 20a, if the resistance Q of the self-induction coil increases without limit, we have simply Maxwell's method, in which an interval between the reversals

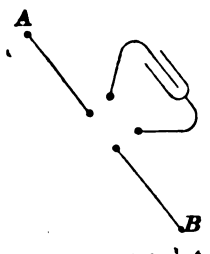

Fig 20a

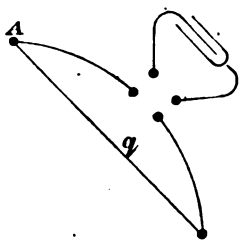

Fig 20b

is advantageous. If, on the other hand, there is no condenser used, a small short-circuit may be allowed to occur during reversal, and its effect eliminated in the way described in the appendix of Profs. Ayrton and Perry's paper. Prof. J. J. Thomson (*Phil. Trans.*, III., 1883) gives a modification of Maxwell's method, which consists of breaking the condenser connection and discharging it, instead of reversing its connections. In Fig. 20c much the same result is brought about by employing a revolving connector, which short-circuits the condenser during a small fraction of a revolution. The formula will have to include a correction for the short-circuiting the arm A B of the bridge while the condenser is being discharged; but this correction need be but very small, for the time constant of the condenser for discharge, being the product of its capacity and the resistance of the short-circuit, is very small indeed, so that the short-circuiting need only last for a very small fraction of a revolution. Figs. 20b and 20d are but extended cases of Figs. 20a and 20c. Maxwell's method may be regarded as a special case of the method represented in Fig 20e. Fig. 20f represents a method of finding self-induction somewhat analogous with that of Fig. 20c, but it has not yielded good results. There are analogous methods of determining mutual induction, but they are not very promising. In these methods the commutator is in the arm of the bridge. This is no disadvantage in the case of measuring capacity, but it is a disadvantage in the case of self-induction unless the resistances of the bridge are much larger than that of the commutator. The connection of these methods with the preceding is shown by Fig. 18. If, instead of discharging the condenser through the galvanometer, the condenser be charged through the galvanometer, we get Prof. J. J. Thomson's modification of Maxwell's method.

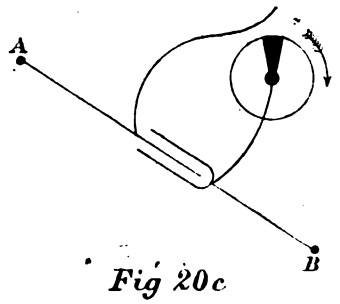

Fig 20c

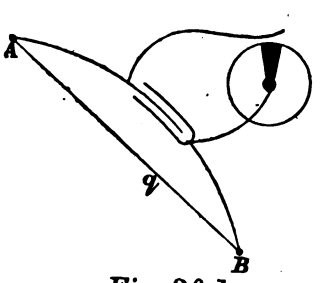

Fig 20d

Fig. 22 represents a method suggested by Prof. Ayrton for determining the coefficient of self-induction of a coil while a particular current is flowing through it. It is but a slight modification of Maxwell's method, and consists in altering by a small amount the current running through the bridge instead of establishing it from zero to its full value. It can be easily shown under the circumstances that

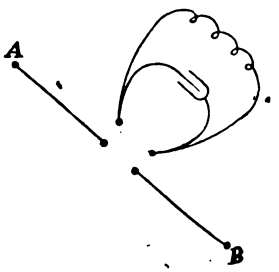

Fig 20e

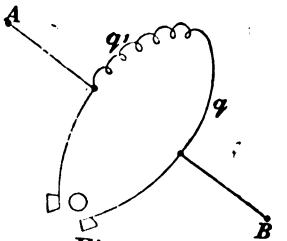

Fig 20f

$$L = \frac{C_1}{C_1 - C_2} \times \frac{\sin \frac{1}{2}\theta}{\tan \alpha} \sqrt{\frac{RT}{\pi^2 + \lambda^2}}\, e^{\frac{\lambda}{\pi} \tan^{-1} \frac{\pi}{\lambda}}$$

where C_1' is the current running through the coil when a derangement R of the arm of the bridge in which the coil is placed produces a steady deflection α on the bridge galvanometer, and $C_1 - C_2$ is the change of current in this arm which, when the bridge is balanced for steady currents, produces a swing θ; T is the period and λ the logarithmic decrement of the same galvanometer.

The experiments, which were performed with the aid of Messrs. Rossiter and Watney, of the Central Institution, were made on the field-magnets of a Gramme dynamo, and also on those of a Ferranti dynamo. The arms A B and A D had resistances of about 10,000 ohms each, B B_1 was the coil whose self-induction was required, D D_1 was a German silver wire of about equal resistance, D_1 D_2 was a very thick German silver wire on which a sliding connector (C) was placed. The D'Arsonval galvanometer G_1 connected A and C through a key. The mercury cups B_1, B_2, were connected by a short-circuit plug, except when the deflection corresponding to known derangment R of the arm B C was required; *a a a* are accumulators, *r r r* is a resistance capable of being inserted more or less into the battery circuit by means of the switch *s*. The currents were changed by moving the switch, and the change of current was read by a second D'Arsonval gal-

Fig 21.

Digitized by Google

vanometer (G_2). By pressing the key K_1 the galvanometer G_2 was shunted to a constant length of the wire $D_1 B_2$, and measured the current absolutely. By pressing the key K_2 the galvanometer was shunted to any convenient length of the wire $D_1 B_2$, and by taking the deflections corresponding with C_1' C_1, and C_2 the ratio $\frac{C_1'}{C_1 - C_2}$ was easily found.

The currents used varied up to 30 amperes, and were sent in both directions. The results show that the coefficient varies with the current, and also with the previous history of the iron. The set of values obtained with an ascending series of currents differs from that obtained with a descending series. The coefficient diminishes rapidly at first, and then more and more slowly. In several cases the results strongly indicate that the maximum value of the coefficient is not that for zero current. This is exactly what it is natural to expect, on the assumption that the self-induction curve is the differential of that of magnetic permeability; for the slope of the latter curve is small at first, increases to a maximum, and then diminishes asymptotically. All the results are, however, much complicated by the fact that the D'Arsonval galvanometer was not sufficiently ballistic. Under these circumstances changing the resistance in the battery circuit alters the time constant of the bridge, although it does not for the same change of current alter the quantity which passes through the galvanometer. The ratio between the swing of the galvanometer and the quantity passing through it was therefore not constant and the results are therefore not accurate.

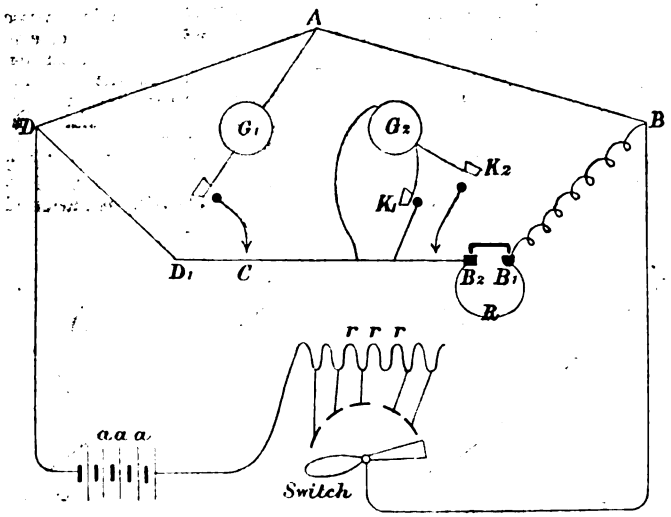

Fig 22.

This method is equally applicable to the measurement of change of coefficients of mutual induction and capacity. It is not easy to render it accumulative. If, instead of making and breaking the battery circuit, the points B and D be periodically shunted and unshunted by a known resistance, it would be necessary to know the resistances in the other parts of the bridge; and this would be difficult if the resistances heat, as they must when large currents are used. In the method just described the only resistance necessary to know was that of R, and this was not allowed to heat.

(*To be continued.*)

PHYSICAL SOCIETY.—June 25.

Mr. Shelford Bidwell, F.R.S., Vice-President, in the chair.

The following communications were read:—

Note on Magnetic Resistance. By Prof. W. E. Ayrton, F.R.S., and Prof. J. Perry, F.R.S.

In the spring of 1886 the authors made experiments on the magnetic induction through horseshoe electro-magnets when excited by constant currents. The inductions through different armatures and air spaces were also measured. The results show that for small exciting powers the law of parallel resistances is true for magnetism, taking leakage into account. From experiments made with two electro-magnets, the poles of which were placed at different distances apart, the authors conclude that the magnetic resistance of air is proportional to length, or to length plus a constant A "Note on Magnetic Resistance" was read before the Society on the 12th March, 1887, by the same authors, describing experiments on two iron rings, one whole and the other divided by a radial saw cut. Since then the experiments have been repeated with great care by Colonel Swinton and Mr. Sorenson, of the Central Institution. The resulting curves agree with those previously obtained. On measuring the air space it was found considerably less than estimated, and the magnetic resistance of air relative to iron (assuming no "surface resistance") comes about 1,500. Experiments made with different air spaces together with the above seem to show a considerable surface resistance. Prof. S. P. Thompson thought dynamo makers had evidence of such "surface resistance" from the care exercised in avoiding joints in the magnetic circuit wherever possible, and Mr. Bosanquet mentioned some experiments he had recently made on the resistance of joints during the various stages of fitting. The changes of resistance are very large, and he concludes that however good the fit it is not possible to reduce the "surface resistance" to a negligible quantity.

On Sounding Coils. By Prof. W. Stroud, D.Sc., and Miss J. Wertheimer, B.Sc.

The paper describes experiments in coils and helices of wire, which emit sounds when variable electric currents are passed through them. The pitch depends on the frequency of the current variations. The authors believe the sounds due to the attractions of adjacent parts of the wire, which cause shortenings and lengthenings as the current increases or decreases. To prove this, two identical coils were made, and one of them embedded in plaster of Paris. This gave no sound when the variable current was passed, whilst the other emitted the usual note. It was also found that no sound could be got from a single turn of wire, whilst one and a-quarter turns gave an audible sound under the same conditions.

On Comparing Capacities. By Mr. E. C. Rimington.

This is an investigation of the conditions under which the integral current through a galvanometer in a balanced Wheatstone bridge is zero, when the battery circuit is broken, two adjacent arms (A and D) of the bridge being shunted by condensers of capacities K_1 and K_2. It is shown that $\frac{K_1}{K_2} = \frac{C}{B}$, where C and B are the resistances of the arms opposite to A and D respectively. If A and D be made infinite the necessity of balancing for steady currents is obviated, but if either of the condensers has an appreciable leakage corrections are required. The best resistance to give to the galvanometer is shown to be $G = \frac{B(C+D)}{B+C}$, and the conditions under which a telephone may replace the galvanometer are $\frac{K_2}{K_1} = \frac{C}{B}$. The case where all the arms have self-inductions is investigated.

On Permanent Magnet Ammeters and Voltmeters of Invariable Sensibility. By Profs. W. E. Ayrton, F.R.S., and J. Perry, F.R.S.

The sensibility of ordinary permanent magnet ammeters and voltmeters increases as the strength of the magnet decreases, whereas in those of the Depretz-D'Arsonval type (in which a suspended coil controlled by torsion swings between the poles of a permanent magnet) the reverse effect takes place. By continuing the two systems the authors have devised instruments whose sensibility is unaltered by changes in the strength of the magnet. The torsional control of the D'Arsonval is removed and a small permanent magnet attached to the swinging coil. As the large permanent magnet changes the controlling and deflecting forces change in the same proportion, and the deflection for a given current remains unaltered.

COMPANIES' MEETINGS.

South of England Telephone Company (Limited).

The third ordinary general meeting of this Company was held on Tuesday last, at Winchester House, Old Broad-street, under the presidency of Mr. D. Owen Bateson.

The Secretary (Mr. Fred. L. Robinson) having read the notice convening the meeting, the report of the Directors was taken as read.

The Chairman said: When I last had the pleasure of seeing you I told you that I expected in future to produce our accounts within six weeks of the termination of our year, which ended 30th April. Our report is dated 16th June, so I think I was not far out in my calculation. I have no doubt but that you have scrutinised the figures that have been presented you, and in your own minds have criticised them. Your Directors consider that under the circumstances they are fairly satisfactory, and I trust you will do the same. Up to nearly the end of the past year we had every reason to be pleased with our progress, and we felt sure that a dividend of 1 per cent. at least would be earned on our ordinary shares. The disastrous storm of the 26th December, in levelling our wires and poles, dashed to the ground all our hopes. Those of you who saw the state of the London streets on the memorable morning of the 27th December can form a very good idea of the condition of our system in most of our centres. It was really an utter collapse in Reading, Northampton, Cambridge, Oxford, Colchester, Ipswich, and Norwich and partially in other places. Fortunately, however, our southern stations were hardly touched, and Brighton and our south coast exchanges did not suffer at all. Well, gentlemen, we set about repairing the damage as quickly as possible, and some of our lines were got into working order pretty quickly. But the main part took a very long time, not so much from the difficulty in running the new lines—though the scarcity of good workmen did in a measure delay us—as the withdrawal of our way-leaves, which hampered us very seriously. The main result was a total loss of fully three months of our existence, as we had to postpone the payment of our rentals quite this time. And even this does not tell the whole story. Our new orders almost ceased entirely in the damaged district during the time of reconstruction; and this was a serious matter, as previously orders to the extent of from £400 to £500 per month were coming in. The total cost of the disaster it is impossible to estimate; but you will notice that we have placed £1,365. 3s. 7d. to debtor of the account, which merely represents our out of pocket expenses. After all, the collapse must not be considered as an unmixed evil, as it taught us a great deal in the way of construction, and we think we have made our system much more secure by adopting pole routes—ground poles where possible—and by avoiding chimney attachments as much as we can. I think it will

Digitized by Google

be found to be so, and that we shall never again have to record a similar disaster, or anything like it. During the year our exchange lines have increased 443, and private lines 100, against 571 and 125 respectively in 1886; and our gross rentals are £11,487, against £7,809 in 1886, showing an increase of £3,678. You will remember that last year's balance-sheet included fifteen months' working, this year only twelve, and from this we must deduct at least three months' loss of time, occasioned by the disaster I have alluded to. Though our progress has not been by leaps and bounds it has been steady and continuous. Your Directors look on the accounts as, under the circumstances, being satisfactory. They have during the past year been engaged rather in developing their old centres than in establishing new ones. We have found it for the convenience of our subscribers in contiguous towns having business relations with each other to connect them by trunk lines; thus Norwich and Yarmouth can speak to one another, and it is not unlikely but that Lowestoft may also be connected with these two exchanges, if we meet with sufficient encouragement to undertake the expense. Northampton and Wellingborough, and Folkestone and Dover are connected, as also Chatham and Maidstone. We are now canvassing for way-leaves between Brighton, Lewes, and Eastbourne, as also between Brighton and Worthing, and we shall proceed with other lines as the demand for them arises. The district in which we work is not a very promising one as regards business. We have few large towns, Brighton being our largest. I may say we have no manufacturing or commercial centres to compare with Bristol, Birmingham, Liverpool, Manchester, Newcastle, and Glasgow. Reading, and its biscuit-baking industry, and Norwich, with its mustard manufactory, are our best. Our district is composed mainly of residents and agriculturists; the former do not require telephones, and the latter, I much fear, cannot afford to pay for them. But we have, I consider, a mine of wealth within our reach if it is only developed. The multitude of City and business men who reside within a radius of 25 and 30 miles of London would—many of them—be thankful to be able to converse with their offices and places of business, and would pay handsomely for the convenience. In addition to this we have applications from towns within a moderate distance of London, who call loudly for communication. Chatham has applied, as also Windsor, Reading, Luton, Cambridge, and several others. We have urged this matter on the consideration of the parent company, the United, but up to the present no satatisfactory terms for the entry of trunk lines on to their system have been suggested. I trust, however, that the time will come, and that with no material delay, when we shall be enabled to carry out some scheme, which will, I am sure, prove of material benefit to both companies. As regards finance, we are certainly in smoother water than when I last saw you. I told you that we had a controversy with the representatives of the late Mr. Kendal as to 13,567 ordinary shares in the Company, which he had agreed to allot to the applicants for a like number of preference shares, the balance of our unissued capital. We were some time before we came to terms with these gentlemen. Ultimately, however, we consented, acting under the strong recommendation of our legal adviser, to accept a compromise of 10,000 ordinary shares in full, and as soon as we got possession of them on the 23rd November they were offered to our shareholders and renters as a bonus on their applying for a similar number of preference shares. There were applications for about 15,000 shares, which was considered to be a satisfactory result. On these shares 30s. each has been called up, the last call of 10s. being due 4th May, and the entire has been paid, with one trifling exception. The greater part of our expenditure, as you are aware, is on capital account, and as you will note from the figures in our report there is a debit of £5,632. 9s. 11d. against capital. In order to square this up we have decided to call another 10s. per share, payable 2nd August, on all our issued preferences, which, being 16,433, will yield us £8,216. 10s. There still remain unissued 3,567 preference shares. We are prepared to receive applications for them, with £2 paid, and are prepared to pay a 6 per cent. preference dividend on them on the terms of our prospectus, carrying interest from the commencement of our financial year, namely, 1st May last. We have, however, no bonus ordinary shares to allot with these. We paid an interim dividend of 6 per cent. per annum on our preferences on the 1st October last, and warrants for a second half-yearly dividend at the same rate will be posted this evening. These amounts, as you will see from the figures presented to you, have been fairly earned. I am sorry that your Directors cannot recommend any payment on account of the ordinary shares, as they at one time hoped to have been able to do. The task imposed on us, namely, to pay a dividend on £300,000 of paper shares is a very onerous one. Were we only to pay 1 per cent. in addition to the 6 per cent. on our preferences, which is a first charge on our net revenue, it would amount altogether to nearly 20 per cent. on our working capital of £22,000. This is a serious undertaking, and it must of necessity be a very good paying concern that can do it. But I, for one, do not despair, and trust that we shall at the end of another year, if no untoward accident again happens, be able to give a good account of ourselves. You may depend on the efforts of those on this side of the table being directed to effect this desirable end.

Mr. T. F. CAMPBELL seconded the motion.

A SHAREHOLDER said he thought that the accounts were not nearly so satisfactory as those for the previous year. The expenses in the last year's balance-sheet, with a revenue of £7,800, were £1,200, and this year, on a revenue of £11,400, the ordinary expenses had gone up to £3,460. He also desired to know how it was that the Post Office royalties had trebled, amounting to over £3,000 in the present balance. After allowing for the amount set aside for the snowstorm the accounts did not come out nearly so favourably. With an increase of nearly £4,000 in the revenue there had been only a net increase of £400, so that the prospect of a dividend on the ordinary shares looked very doubtful. He understood the Chairman at the last meeting to state that a dividend was in sight for the ordinary shareholders, and it was also in print that 1½ per cent. on the ordinary shares was carried forward then. He thought that the state of the Company's position ought to have been brought before the shareholders by circular, for during the whole of the year which had elapsed since their last meeting the ordinary shares had been changing in the belief that a dividend was to be soon paid on them. As late as a fortnight before the issue of the report he was told by a stockbroker that there was to be a dividend this year on the ordinary shares. The shares had been changing hands at 5s. to 6s., making the total market value of those shares between £70,000 and £80,000. With the increase in the preference shares it seemed to him that the ordinary shares are being put out of court altogether.

The CHAIRMAN stated that the trunk wire between London and Brighton was the property of the Post Office and the United Company, and the South of England Company paid a rental for it. All the trunk lines between Norwich and Yarmouth, and so on, belonged to this Company; but when they came into London the case was different. As soon as ever they could make a line to pay, they would run such a line. They got their agreements signed before they ran the line. Referring to the shareholder who had first addressed them, he said that the Directors could not be held responsible for what that gentleman had been told by stockbrokers as to the value of the ordinary shares, respecting which the Board had given no indication. Although a certain amount had been carried forward at the last meeting, there were all the expenses to come off. The snowstorm had caused them a very large outlay. They would have been able this year to have paid 1 per cent. on the ordinary shares but for the snowstorm, and he thought that 1 per cent. on £300,000 would be an uncommonly good dividend. In answer to another shareholder the Chairman stated that the claim (referred to at the foot of the balance-sheet) for £633 for royalty on surplus instruments was a matter of account between the United Company and the Company.

Mr. QUILTER, M.P., said he was quite sure as a Director of the United Company, who were very large shareholders in this Company, that nothing but what was right and fair would be required by the parent company. He certainly agreed with one of the shareholders who had already spoken, that the result of the past year's working by the Company had been very unsatisfactory. He might be wrong, but he regarded the field possessed by the Company as one of the best for telephonic enterprise in England. He would be more than disappointed if on the next occasion there was not quite a different balance-sheet. It was impossible to hold Directors responsible in connection with any purchase of shares, but he did feel that a great deal was to be said in favour of half-yearly meetings—a suggestion which he would be quite ready to support if the hon. shareholder who had raised the point would bring the matter forward by way of a substantive resolution.

The CHAIRMAN said he could not agree with Mr. Quilter that the Company had a very good district, which, as a matter of fact, was rather barren. The Directors had worked as hard as they could to promote the welfare of the Company, and they had great hopes of doing better; but they had been seriously affected by the snowstorm.

Dr. ELLIS, of Eastbourne, referred to the prominent part which he had taken to induce the Town Council there to allow the use of overhead wires. The progress of the enterprise at Eastbourne had been rapid, and he thought that within the last twelve months the Company had done all that could reasonably have been expected from it. Owing to the executors of the late Chairman holding the ordinary shares for some time there was a difficulty in raising the additional capital required, and no doubt 12 or 18 months ago they were not in a position to raise sufficient capital to carry out the necessary works. As soon, however, as the present Board obtained capital, the results were at once seen. Judging from what had been done at Eastbourne, he thought that the Directors had displayed considerable energy. The shareholders ought not to forget the adverse effect on the Company of the snowstorm. At no very distant period the Government had the option of taking the lines, and therefore it was to the interest of the Directors and the shareholders that the system should be developed on the largest possible scale in the shortest possible time. He suggested that the Directors might, by means of lectures, at the cost of a few pounds, endeavour to make the uses of the telephone more generally known.

The CHAIRMAN said that the Directors would consider the subject of half-yearly meetings, with every desire to carry out what was wished; but there was some difficulty in connection with the accounts.

At the instance of Mr. WILLIAM ROE a resolution was passed expressing the opinion of the meeting in favour of half-yearly meetings, at which the Chairman should make a statement as to the progress of the Company, but at which a balance-sheet need not be presented.

The CHAIRMAN, in reply to a question, said that there would be no difficulty in informing the shareholders at the meetings of the number of subscribers at each of the towns as compared with the number at the time of the previous meeting.

Mr. HENRY ROBERTS then proposed, and Mr. W. A. MACGREGOR seconded, the resolution to the effect that the Directors should receive the sum of £700 for their services during the twelve months ended 30th April, 1887.

The CHAIRMAN, in explanation, said that immediately after the last meeting the Directors appointed him Managing Director at a remuneration of £500. That resolution was handed to the United Company, who referred it to Mr. Brand, who decided—and they had that gentleman's letter to that effect—that the £500 should be passed; but it was to appear in the way the mover of the resolution had put it. He (the speaker) gave his whole time to the affairs of the Company.

A SHAREHOLDER said that the shareholders were asked to augment their expenses by £500 a year in a very bad year.

The CHAIRMAN said that that was not the case. The amount mentioned was in the accounts. Part was in the item of general management,

Digitized by Google

salaries, &c., and part had gone to construction account, because half his time was spent in the country.

After some further discussion,

Mr. QUILTER stated that he knew nothing about the approval of the United Company having been given in regard to the question under discussion.

Mr. ROE moved and Mr. FITZGERALD seconded a resolution adjourning the meeting for a fortnight for the purpose of completing the business, which was passed.

On the motion of Mr. QUILTER, a vote of thanks was passed to the Chairman, and the meeting then separated.

United Telephone Company (Limited).

Report of the Directors for the year ending 30th April, to be presented to the shareholders at the seventh annual ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, E.C., on Tuesday, July 5th, 1887, at two o'clock :—

A reference to the capital account will show that up to the 30th April, 1887, the sum of £228,180. 12s. 2d. had been expended upon the works in connection with the Metropolitan District and instruments on royalty in the Metropolitan District and subsidiary companies, being £41,513. 18s. 2d. more than the outlay shown in the last balance-sheet. The revenue accounts, exclusive of Metropolitan District royalties, show that the receipts of the Company from all sources properly attributable to the year have been £130,704. 7s. 5d., as against £122,283. 15s. 1d. in the preceding year, or an increase of £8,420. 12s. 4d., and the expenditure (including snow storm expenses, &c., £15,777. 0s. 8d.), has been £66,954. 11s. 8d,, as against £54,681. 6s. 1d., or an increase of £12,273. 5s. 7d. The working expenses of the Metropolitan District for the year have been £30,483. 14s. 2d., as against £32,548. 4s. 8d. for the preceding year, or a decrease of £2,064. 10s. 6d. The balance of net revenue account is £62,235. 17s. 3d., of which amount the sum of £22 377. 15s. has been absorbed by the payment of an interim dividend at the rate of 10 per cent. per annum for the first half year ended 31st October, 1886, and the Directors recommend a further dividend of 8s. per fully paid £5 share (part paid shares receiving in proportion) for the second half year ended 30th April, 1887, amounting to £35,804. 8s., making a total dividend of 13 per cent. for the year, leaving a balance of £4,053. 14s. 3d. to be carried forward. A sum of £4,203. 9s. 10d., representing profits derived from exceptional sources, &c., has been carried direct to the reserve fund, in addition to the amount set aside for depreciation on instruments. Mr. James Brand, Mr. James Staats Forbes, and Mr. Joseph B. Morgan retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Quilter, Welton and Co., and Messrs. Price, Waterhouse and Co., also retire.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 24th inst. amounted to £4,147.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due on the 30th inst. on the debentures of this company will be paid by Messrs. Barclay, Bevan and Co. The coupons must be left three clear days for examination. The directors have declared an interim dividend of 4s. per share, free of income-tax, in respect of the first half of 1887, payable 15th July, 1887.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 24th inst. amounted to £3,429, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NOTES.

EDISON.—Mr. Edison, it is said, is about to construct a great experimental laboratory at his home in Orange, New Jersey.

TENDERS FOR LAYING UNDERGROUND WIRES.—In our advertising columns particulars will be found as to the laying of underground wires required by the Hornsey Local Board.

THE PORTRUSH ELECTRIC TRAMWAY. — The Portrush electric tramway has now been extended from Bushmills to the Giant's Causeway, and the extension has been in use since the 1st inst.

TELEGRAMS BY TELEPHONE.—The delivery of telegrams by telephone has become very popular in Belgium. The average number of telegrams passing through the telephone exchanges daily now exceeds 1,200.

THE INTERNATIONAL CONFERENCE ON SUBMARINE CABLES. The International Conference on the protection of submarine cables, which suspended its sittings in December last, meets again this week in Paris, under the presidency of M. Flourens.

ROYAL SOCIETY OF VICTORIA.—We have received copies of the 22nd and 23rd volumes of the *Transactions* of the above society. These volumes contain a paper on "Systems of Electric Lighting," by Mr. J. Booth, and one on "Lightning Conductors," by Prof. W. C. Kernot.

THE ELECTRIC TELEGRAPH JUBILEE DINNER.—The meeting of the committee, which in our last issue we announced to be held on Tuesday, July 5th, should have referred to the *sub*-committee. The next meeting of the general committee will be held on Tuesday next, July 12th.

SPAIN.—The Madrid paper, *El Imparcial*, states that active preparations are being made for the installation of the electric light at Pontevedra in the province of Galicia.—It is reported that Madrid is to be added to the list of towns in which the electric lighting of theatres has been made compulsory.

IRON TELEGRAPH POLES.—A local paper states that Messrs. Bayliss, Jones and Bayliss, of Wolverhampton, have secured an order to supply a colonial market with 50,000 iron telegraph poles. This order is probably the one referred to in the specification published in this journal on the 24th ult.

TOLEDO, SPAIN.—The municipal authorities have decided upon adopting the electric light for public lighting, and a notification dated Toledo, 30th June, appears in the Spanish papers inviting proposals to be sent in within a period of 45 days from that date. The conditions can be seen at the Secretaria Municipal do Toledo, and in the leading towns of the province.

RAILWAY CARRIAGE LIGHTING IN GERMANY.—A train of six carriages on the Main-Neckar Railway, running between Darmstadt and Heidelberg, has been lit during the past month with electric light. Each carriage is supplied with two secondary batteries containing each eight Khotinsky cells. One of these batteries is in use while the other is being recharged by a dynamo placed in the guard's van.

THE OERLIKON DYNAMO.—In the Liverpool Exhibition (Machinery Court). Mr. B. H. Thwaite, C.E., has just fixed an Oerlikon dynamo. This type, patented by Mr. C. E. L. Brown, has given wonderfully high efficiency results, stated to be 98 per cent. electrical and 96 per cent. commercial. In this dynamo there is no sparking at the brushes. The machine is described as a perfect model of mechanical engineering.

TENDERS WANTED FOR PUBLIC LIGHTING.—In our advertising columns particulars will be found as to the lighting of the town of Malton, about which the local authorities would like to hear from some of the electrical engineers.—Tenders are also asked for lighting 120 public lamps in the district of Great Ilford (Essex) "with gas, paraffin oil, or electric light." Further information may be obtained from Mr. A. Sherman, clerk to inspectors, 1, Oakfield-road, Ilford.

"JOURNAL OF THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS."—The sixty-seventh issue of this journal, which has just been issued, contains the papers by Profs. Ayrton and Perry on "Self and Mutual Induction," and the paper by Mr. W. E. Sumpner on the same subject; also the paper on "Underground Telegraphs," by Mr. C. T. Fleetwood, and on "Driving Dynamos by Very Short Belts," by Profs. Ayrton and Perry, together with the several discussions.

THE LIGHTING OF THE CITY OF LONDON.—At the last meeting of the Commissioners of Sewers the clerk submitted a notice of Messrs. Bircham and Co., on behalf of the South Metropolitan Electric Supply Company, that application is intended to be made under the Electric Lighting Act, 1882, in the ensuing session, for a Provisional Order for power to supply electricity for lighting and other purposes in certain streets and places within the City. It was referred to the Streets Committee.

THE FINSBURY TECHNICAL COLLEGE.—The students' *conversazione* at the Finsbury College on Friday next promises to be a more than usually interesting affair. In addition to the usual display of scientific apparatus, &c., there will be a lecture by Prof. Ayrton on "Church Bells," illustrated by working models, and one by Prof. Neldola on "Spectrum Analysis." An illuminated fountain will play in the court yard, and the concert to be given in one of the rooms will be transmitted telephonically to another part of the building.

THE WEST METROPOLITAN TRAMWAYS.—The Bill promoted by the West Metropolitan Tramways Company to authorise the use of electrical or other mechanical power on their existing tramways came again before a Select Committee of the House of Commons on the 12th inst. The Metropolitan Board of Works appeared as opponents, on the ground that it was *ultra vires* for the provisional order which the Bill confirms to be issued without the consent and approval of the local authorities. The Committee, however, passed the Bill.

BOURNEMOUTH.—On Thursday evening a lecture on "Lighting, Past and Present," was delivered before the members of the Bournemouth Society of National Science by Mr. Octavius Curtis. The latter part of the subject was illustrated by a number of arc lamps of various types which had been lent by Messrs. Mortimer, Shepherd and Co., a firm which, as our readers are aware, has been running an electric station at Bournemouth during the last few months. We were pleased also to learn that there is a probability of the installation assuming a permanent character.

WHERE WAS IT?—From the top of Titterstone Clee Hill, in Shropshire, on the night of the Jubilee celebrations, about 100 bonfires were visible. Amongst these a brilliant white glare, in the direction N.W. by N., was universally believed to be due to the electric light, but it has not yet been discovered from what locality it proceeded. A line drawn on the Ordnance Map in the direction indicated passes over the towns of Shrewsbury, Chester, and Liverpool, distant respectively as the crow flies 20, 55, and 67 miles. It appears that neither at Chester nor at Shrewsbury were any electric lights displayed on the 26th ult. It would be interesting to know whether a light at Liverpool was actually visible from this distance.

THE ELECTRIC LAUNCH "THE COUNTESS."—It is stated that Elieson's electric launch will go down to Spithead for

Digitized by Google

the Naval Review on the 23rd inst. Our readers will remember that this boat carries on board an engine to be used for recharging the accumulators. On the authority of a paragraph in a daily journal we now learn that this engine "derives its power from the force accumulated by the vessel's passage through the water." The engine charges the accumulators, the accumulators drive the motor, the motor propels the vessel, and the vessel "accumulates" the power which works the engine. Mr. Elieson has doubtless been grossly libelled by the reporter in being made to appear as a perpetual motion man.

CENTRAL STATION LIGHTING IN PARIS.—The opening of the Montmartre central station will very shortly be followed by a second in the neighbourhood of the Pantheon, where a 2,000-light plant is now being erected by the Société d'Oerlikon.—M. Philippart has applied for the authorisation of a scheme for lighting all the public buildings in Paris by means of accumulators to be charged from a central station.—A similar scheme (and one we should say with as little chance of success) has been set on foot by the Société pour la Transmission Electrique de la Force, which proposes to light all the theatres in Paris from a single station.—The new Opera Comique will be lit by the Edison Company.

PRICE LIST.—Mr. G. Sharples, of Preston, sends us a copy of his illustrated descriptive catalogue and price list, which contains a remarkably extensive list of physical and chemical apparatus of all kinds. Mr. Sharples is well known as having had the good fortune to acquire a large stock of royalty-paid Gower-Bell telephones at the time when the instruments were in the market. The list before us contains also a good deal of useful information for amateurs and others on such subjects as the proper way of using and maintaining batteries of various types, methods of connecting electric bells, annunciators, and telephones, and the fixing of lightning conductors; also information concerning the Science and Art Department and grants in aid of the purchase of apparatus for science schools, &c.

CONVERSAZIONE AT THE SCHOOL OF TELEGRAPHY, PRINCE'S STREET, W.—On the evening of Friday, July 1st, a *conversazione* was held at the School of Telegraphy and Electrical Engineering, in Prince's-street, Hanover-square. The guests were received by Mr. Wm. Lant Carpenter and Mr. Leon Drugman, and found much to interest them in the display of electrical and physical apparatus, the lantern "lecturettes," by Mr. A. D. Wilkinson and Mr. E. C. Rimington, and the very enjoyable musical programme which had been provided. A loan collection of apparatus was also on view, to which the principal contributors were Messrs. Nalder Brothers and Co., Messrs. Immisch and Co., and Messrs. F. E. Becker and Co. Amongst those present were Prof. Silvanus Thompson, D.Sc.; Mr. Swan, F.C.S.; Dr. Fleming, Mr. Desmond FitzGerald, Mr. Sidney Sharp, Mr. W. B. Esson, Mr. Immisch, and many old pupils of the School.

THE ELECTRIC LIGHTING BILL.—It is stated that Mr. Hugh Watt intends shortly to give notice in the House of Commons of the following resolution:—"That the Electric Lighting Amendment Bill introduced by Lord Thurlow in the House of Lords having been deprived of its most important provision by the decision of the Committee of that House, and thus rendered useless for the purpose for which it was intended, no measure short of a repeal of the Electric Lighting Act (1882), and the substitution therefor of legislation rendering it possible to supply electric light to the public with a fair prospect of remunerative returns, will be of any benefit to the electric lighting industry, and as that Bill has to a very large extent destroyed the growth of the industry in this country and driven the export trade into American hands, it is desirable that the aforesaid Act be forthwith repealed, and those engaged in this new industry (which now employs nearly £50,000,000 of capital, and over 50,000 workmen in America) be freed from the fetters of legislation, which have proved of so disastrous a character."

BATH.—During the Jubilee celebration at Bath the market place was illuminated by Mr. Massingham with a Thomson-Houston 30 arc light plant; and on Monday last a lecture on electric lighting was delivered in the theatre by Mr. Wharton, the mayor occupying the chair. Considerable interest was manifested by the audience, and at the close of the lecture Mr. Wharton replied to a number of questions. We regret to learn that a misunderstanding of some kind has subsequently arisen between Mr. Massingham and the Corporation, and the lights in the market place were ordered to be removed several days earlier than had been originally intended. The local journals publish a correspondence between the parties concerned, but the origin of the squabble is not made very clear. In erecting the lamps, Mr. Massingham had been allowed to use the fire escape to reach the front of the Guildhall, but the officials thought proper to refuse this facility for their removal. Whatever may be the actual merits of the quarrel, an incident of this kind is unhappily sufficient to prove the narrow-minded provincialism of the authorities of the ancient city of Bath.

BERLIN.—The Berlin correspondent of *Industries* states that some large and comprehensive schemes for the extension of the existing central electric light stations, and the establishment of two new ones, have fallen through, the reason being a disagreement between the Town Council and the Edison Company. Hitherto the fitting up of the electric light on the consumers' premises has been carried out by the Edison Company; but the Town Council wanted to secure to consumers the right of having their installations fitted up by third parties, the electric light company to supervise and pass the work, for which they were to be paid at the rate of 10 per cent. on the cost, whilst the supervision for work done for the municipality would only be paid at 5 per cent. on the cost. To these innovations the Edison Company would not agree, and the negotiations were thus brought to a close. The central stations under the management of the town will now be increased so as to furnish current for 40,000 glow lamps. Experience has shown that out of the total number of lamps fixed only two-thirds are ever lighted simultaneously, and therefore the enlarged stations will be able to serve a district containing 60,000 lamps.

THE CAUSES OF DEATH BY ELECTRICITY.—The *Lancet* remarks that the observation of M. D'Arsonval that dynamic discharges and alternating currents do not (like static discharges) produce serious organic disruption of the lining tissues is not a new discovery. The special disruptive and fatal effect of the statical discharge has long been known in this country, and was most fully brought out in Dr. Richardson's experiments on death by electric shock, conducted in the Royal Polytechnic Institution in 1869. In those researches sheep and other animals were killed by the statical discharge, and the cause of death was shown to be due to the sudden expansion of gaseous parts of the blood and tissues, by which organic lesions of the most extensive kind were induced. In one of this series of experiments the skull of a dead animal was fractured by the statical discharge, and arborescent markings of external veins, distortion of large veins, rupture of the heart, ecchymosis, rupture of the stomach, and decomposition of the blood itself, from the same kind of discharge, were phenomena

Digitized by Google

traced to disruption from gaseous expansion. At the same time the statical discharge does not always kill. It may simply stun, or cause a temporary anæsthesia, or produce a state resembling catalepsy, followed by recovery.

THE GAS INSTITUTE.—The annual general meeting of the Gas Institute was held last week at Glasgow. The President (Mr. William Foulis, M.I.C.E.) made the following sensible remarks upon the relations between electricity and gas:—"Notwithstanding the continued depression of trade throughout the country gas manufacture continues to prosper. The quantity produced is steadily increasing, greatly due, no doubt, to the varied uses to which gas is being applied. The most timid shareholder no longer fears electricity as a possible extinguisher of gas, although this system of lighting is also making progress; and with so many minds engaged in its development it must progress both in efficiency and economy. In both of these respects gas lighting is still well in advance. Our duty is not in any way to impede the development of electric lighting, but rather to render it every assistance, while at the same time we strive to cheapen and improve the mode of lighting in which we are more immediately interested. We have to thank the introduction of electric lighting for much of the progress that has been made in recent years in improving the lighting power of gas, in creating a demand for more brilliant illumination, and in stimulating invention to supply the demand."

TRANSFORMER EFFICIENCIES.—In another column will be found a note by Captain Cardew (which we reprint from *Industries*) on the efficiency of the Gaulard-Gibbs transformer. It is satisfactory to find that these tests are in agreement with earlier measurements in assigning an efficiency of considerably over 90 per cent. Captain Cardew's note is interesting also as affording a confirmation of Mr. Kapp's recent theoretical prevision that the limiting value of the sum of the angles expressing the lag of the primary current over impressed E.M.F., and the lag of magnetisation over the primary current is always 90°, and this value is approached asymptotically as the efficiency increases. In the series of experiments in which the periodic time (or number of revolutions) was allowed to vary, seeing that the efficiency of a transformer is a function involving this quantity, it is rather a pity that the speed of the machine is not given in the tables. It is obvious that the efficiency of a transformer would increase continuously with the rate of alternations if it were not for the simultaneous increase of Foucault currents in the core; hence every transformer has a particular value of the periodic time for which its efficiency is highest, and that type of transformer in which the Foucault current loss is least will naturally have its highest efficiency at a relatively higher output.

ERRORS IN TRANSMISSION.—Errors in the transmission of telegrams, says the *Evening Standard*, very frequently occur, but it rarely happens that the consequences of such errors are sufficiently serious to induce the receivers of the incorrectly transmitted message to bring an action for damages for shock to the system. This, however, has been the case in America, the plaintiff being a Mr. Laviolette, a New York business man, who has sued the Western Union Telegraph Company under the following circumstances:—He resided in Astoria, and some time back started for Syracuse to see his son, a pupil at a boarding school near that place, intending to accompany him home. On the arrival of the train at a certain station a Western Union telegram was handed to Mr. Laviolette, which read, "Lewis (the son) is dead." It was signed by his wife, and, greatly shocked at the news, the father continued his journey to Syracuse, where he expected to find the boy's corpse; but on reaching his destination he learned that his son had left by rail on the previous day. He could learn no tidings of him on the route back, and concluded that he must have been killed in some railway accident. Reaching his home in Astoria, he was agreeably surprised, however, to find the boy with his mother, alive and well. It turned out that the message sent by his wife was—"Lewis is home," and that all his anxiety, suspense, and suffering were due to an error in transmission. Under the circumstances, Mr. Laviolette determined to sue the telegraph company, claiming $2,000 for shock to his system, loss of time, and expense occasioned by the delivery of an untrue message; the hearing of the case is to come on shortly.

COST OF ELECTRIC LIGHTING AT BREMEN.—The *Deutsche Bauztag* says that during the progress of the dredging operations which have been going on day and night in the harbour at Bremen it was decided to replace the lanterns and petroleum flare-lights by the electric light, and the contract was given to Messrs. Schückert, of Nürnberg, their tender being the lowest. They were able to reduce the cost of the installation by utilising the surplus power of two steam boilers at the chief pumping station, and by making use of a 25 horse-power reserve engine, already in position, to drive the dynamo, the arrangements being such that the engine could also be made to work a centrifugal pump if required. The engine was driven at 180 revolutions per minute, and the dynamo of the Schückert type constructed to give a current of 16 amperes with 840 revolutions per minute, but 14 or 15 amperes only were utilised in the present case. The light was obtained from 12 arc lamps, each of about 3,000 candle-power, enclosed in clear glass globes of 45cm. in diameter, furnished with overhead reflectors a metre in diameter, and attached to masts 20 metres high. The circuit wires were suspended on ordinary telegraph poles six to seven metres high by means of porcelain insulators. The total cost amounts to 3·62d per lamp-hour. The electric light has been found much more satisfactory than the petroleum lights, especially in wet or stormy weather, when the latter, besides being frequently extinguished, consumed about twice as much petroleum as in fine weather. Experiments are now being carried out to determine how many of the petroleum lights would be required to produce an illumination equivalent to that of one of the arc lamps.

DR. O. FRÖLICH ON DYNAMOS.—Dr. Frölich, writing in the *Electrotechnische Zeitschrift*, gives some measurements upon the increase in the impedance of the armature of a Siemens D_2 machine with increasing velocity of rotation. The armature resistance measured 0·3 ohm. When mounted in a wooden frame, and run at 1,100 revolutions, the impedance was 0·911 ohm; while, when in position in the machine, the impedance amounted to no less than 3·62 ohms, the difference being, of course, due to the increased magnetisation of the core. Dr. Frölich makes the remark that the coefficient at a given velocity is independent of the position of the brushes, and also of the magnetic intensity of the armature field [current in armature]. This, however, merely shows that the machine was working on the horizontal part of the characteristic. He adds that in the machine used as a motor there is some variation which requires further investigation—a conclusion at which several other investigators have arrived. The chief discrepancy is undoubtedly due to the fact, pointed out by Mr. Mordey, of the different relations of the Foucault currents in the two cases; but this does not seem to cover the whole of the ground. Dr. Frölich, in conclusion, advances the opinion that the characteristic curve of a machine is not the

Digitized by Google

end of the theoretical discussion, but rather the beginning, and gives a solution of only a few points required, and by no means an insight into the behaviour of the machine; and to the "knights of the characteristic" he propounds the following proposition:—Given, for a simple shunt-wound machine in which the armature exerts considerable reflex action, a series of experimental observations with different external resistances and velocities; required, the electrical qualities of the machine demonstrated in such a manner as to give a sufficiently accurate solution without special difficulty, and at the same time an insight into its internal economy.

THREEPENNY TELEGRAMS.—Mr. E. Cox-Walker, of Darlington, writes to the *Northern Echo* as follows:—"The idea of the above, when we have only just entered upon the 'sixpenny' state, may seem somewhat premature—and perhaps it is—but only slightly so, and then only so long as it would take the Postal Telegraph Department to prepare for it. The wonderful way in which the reduction to sixpence has increased the use of the telegraph, and rendered its further development so desirable to all commercial men in particular, is my reason for indicating what it must shortly come to, and the way in which this further reduction in the price would influence and enormously extend the use of the telegraph may be gathered from a consideration of the present cost of a letter with its penny stamp, paper, and envelope, and the time occupied in writing. There cannot be a doubt in any one's mind as to the enormous increase that would take place, and the benefits which would arise therefrom to the commercial world, which is really the great user of this mode of communication. The cost of transmitting messages will, of course, be greatly reduced, as regards each message, by the full use made of all the instruments and wires. Then the capacity of the carrying power of the wires is being greatly increased by the substitution of copper for iron wires by the Telegraph Department; and the speed at which signals and words can now be transmitted has been wonderfully increased during the last year or two—news being now sent at the rate of 450 words per minute between London and Ireland and elsewhere. There is also an immense increase in the number of the wires between town and town during the last few years; and the telephone companies have made us acquainted with the fact that messages are constantly passing between their subscribers in and about London at an average cost of about a penny. Everything, therefore, seems to point out to us that the Postal Telegraph Department might, at any time when they are prepared to do the enormously-increased work, reduce the charge to threepence for twelve words, to the great advantage of the country at large."

THE POSTAL TELEGRAPH SERVICE.—In the House of Commons on Friday last Mr. Raikes, in answer to Mr. De Lisle, said:—"The accounts for the last financial year have not yet been closed, and I am therefore unable to furnish any more definite information as to the deficiency in the telegraph revenue than I did on the 6th ult., when the votes for the Post Office were under discussion in this House. I then stated that there was a permanent charge of £326,000 for interest on capital, and that the actual deficit on the working of the telegraph system was estimated at £223,000, making a total deficit for the year of about £550,000. The estimate of a loss of £223,000 on the working of the system has reference to the whole of the telegraphic business of the Department, including inland telegrams, foreign telegrams, press telegrams, the rentals of private wires, and various other branches of the business. So soon after the introduction of the reduced rate I do not see my way to advise Her Majesty's Government to make any further alteration in the charge for telegrams; and although, for some reasons, it would be better, both for the public and the Department, that the registration of abbreviated addresses should be abolished, I think it would be difficult to withdraw the privilege of registration at present. I will, however, cause the system to be carefully watched, and will not lose sight of the suggestion made by the hon. member. I regret that it is not in my power to state what is the present proportion of stock and betting messages, but a return is now in course of preparation, which I hope to be able to publish before the end of the year, giving the desired information for a week just prior to the introduction of the new rate and for a corresponding week of last year. I do not see how arrangements could be made to deliver telegrams free at the houses of persons who live in places outside the free delivery of any telegraph office without increasing the loss which is already incurred on the telegraph business of the country."

THE INSTITUTION OF CIVIL ENGINEERS.—In the Court of Queen's Bench last week a case came before the Lord Chief Justice and Mr. Justice Field, in which the question involved was whether the Institution of Civil Engineers was liable to assessment under the Customs and Inland Revenue Act of 1885, which provided that corporate bodies should pay 5 per cent. on the annual value, income, or profits, of their property, in lieu of probate, legacy, and succession duties, it being contended on behalf of the Institution that it came within the exemption contained in the Act applying to property legally appropriated or applied for any purpose connected with any religious persuasion, or for any charitable purpose, or for the promotion of education, literature, science, or the fine arts. The Solicitor-General (for the Inland Revenue authorities) argued that this was not an association for the promotion of education, literature, science, or the fine arts within the meaning of the Act. It was an association of gentlemen, who for their own purposes and advantages in their profession came together and provided themselves with appliances which were very necessary for the objects they had in view. Mr. Charles submitted that the institution was covered by the exemption, as it was devoted to education with regard to the promotion of mechanical science. Last year there were 900 students connected with the institution. The Lord Chief Justice was of opinion that the institution was liable to pay the duty, on the ground that the exemption applied to associations generally devoted to education, literature, science, and the fine arts, and this association was only for the promotion of a particular branch of knowledge, for the purpose of increasing the intelligence and cultivation of a particular profession. If this institution were exempted it would be difficult to know where to stop in regard to the exemption of teaching institutions. Besides, the point was concluded by authority, it having already been held that this very institution was liable to pay poor rates, although there was a slight distinction, inasmuch as the Act in that case provided that associations to be exempt should be exclusively devoted to charitable or educational objects. Mr. Justice Field concurred. Judgment for the Crown accordingly, with costs.

OPPOSITION TO THE ELECTRIC LIGHTING OF THEATRES IN PARIS.—The movement in favour of effecting the compulsory lighting of theatres by electricity is being energetically opposed by a portion of the Parisian press. The extraordinary and practically prohibitive regulations, which were drawn up by the Prefecture of Police before the catastrophe at the Opéra Comique, and which still remain in force, tend also to show that the opponents of electricity are able to exercise considerable influence in certain quarters and will not scruple to avail

Digitized by Google

themselves of every weapon within their reach. Only upon such grounds does it seem possible to account for an article which has appeared in *La Liberté*, and has been reproduced in one of the financial journals. This article begins by pointing triumphantly to the action of the French insurance companies, who at present require an increased premium upon the introduction of the electric light, though we have little doubt that, eventually, the example of the English offices in this matter will be widely followed. The writer sapiently proceeds in the following strain :—"Electricity is not, after all, that which we call lighting, it is a universal property of matter. In introducing electricity into a place of public entertainment, we add one danger more, a special and frightful (*fondroyant*) danger, which has already made many victims. But this is not all ; in order to produce electricity—as we do not at present know how to bottle up natural electricity, atmospheric and terrestrial—we are driven to create the magnetic current, and to establish in the building powerful steam or gas engines whose presence gives rise to a double risk of fire or of explosion. Still further, the wires develop an intense heat which frequently sets fire to adjacent woodwork. This effect is above all produced when the consumption of current is less than the production. In theatres, the scintillation of the light rapidly becomes insupportable. We are, moreover, to be exposed to sudden extinctions, which would give rise to the greatest inconvenience, unless, indeed, we employ accumulators. But these latter offer such numerous chances of accident that even when they are purchased, people seldom dare to use them (!) as in the Hotel de Ville of Paris, for instance." We need waste no time in commenting upon this preposterous article, which in every sentence displays the grossest ignorance and the most reckless perversion of the truth.

THE ROYAL METEOROLOGICAL SOCIETY.—At a meeting of this society, held on June 15th, the following papers, amongst others, were read :—"Note on a Display of Globular Lightning at Ringstead Bay, Dorset, on August 17, 1876," by Mr. H. S. Eaton. Between four and five p.m. two ladies who were out on the cliff saw surrounding them on all sides, and extending from a few inches above the surface to two or three feet overhead, numerous globes of light, the size of billiard balls, which were moving independently and vertically up and down, sometimes within a few inches of the observers, but always eluding the grasp; now gliding slowly upwards 2ft. or 3ft., and as slowly falling again, resembling in their movements soap-bubbles floating in the air. The balls were all aglow, but not dazzling, with a soft superb iridescence, rich and warm of hue, and each of variable tints, their charming colours heightening the extreme beauty of the scene. The subdued magnificence of this fascinating spectacle is described as baffling description. Their numbers were continually fluctuating; at one time thousands of them enveloped the observers, and a few minutes afterwards the numbers would dwindle to perhaps as few as twenty, but soon they would be swarming again as numerous as ever. Not the slightest noise accompanied this display.—"Ball Lightning Seen during a Thunderstorm, on July 11th, 1874," by Dr. J.W. Tripe. During this thunderstorm the author saw a ball of fire, of a pale yellow colour, rise from behind some houses, at first slowly, apparently about as fast as a cricket ball thrown into the air, then rapidly increasing its rate of motion until it reached an elevation of about 30°, when it started off so rapidly as to form a continuous line of light, proceeding first east, then west, rising all the time. After describing several zigzags, it disappeared in a large black cloud to the west, from which flashes of lightning had come. In about three minutes another ball ascended, and in about five minutes afterwards a third, both behaving as the first, and disappearing in the same cloud.—"Appearance of Air Bubbles at Remenham, Berkshire, January, 1871," by the Rev. A. Bonney. Between eleven and twelve a.m. a group of air-bubbles, of the shape and apparent size of the coloured india-rubber balls that are carried about the streets, were seen to rise from the centre of a level space of snow within view of the house. The bubbles rose to a considerable height, and then began to move up and down within a limited area, and at equal distances from each other, some ascending, others descending. These lasted about two minutes, at the end of which they were borne away by a current of air towards the east, and disappeared. Another group rose from the same spot, to the same height, with precisely the same movements, and disappeared in the same direction, after the same manner.

THE JUBILEE OF THE TELEGRAPH.—At the Jubilee meeting of British electricians, held in New York on June 20, Mr. F. W. Jones, general manager of the United Lines Telegraph Company, in responding to the toast of "Our Profession," spoke as follows :—To me having been assigned the honour to acknowledge in behalf of the telegraph the toast so heartily dedicated to "Our Profession," I deem it incumbent on me as an American citizen to pay my respects, first of all, to the foremost object of this celebration, the golden anniversary of the reign of your gracious Sovereign, in whom "a thousand claims to reverence close, as mother, wife, and Queen," and in behalf of the American members of the telegraph I proffer our united congratulations to the illustrious electricians who have met here to night to pay loyal homage to their revered ruler ; and we cherish the hope that Victoria may long be spared to continue her fostering care over science and art, and to use her good offices in the furtherance of peace and goodwill between our respective countries, and may the stars and stripes, the banner of the brave and the free, ever lovingly entwine its folds with the folds of the union jack, which "has braved a thousand years the battle and the breeze." I come now to a more delicate part of my duty in responding to the toast proposed in honour of our profession. In doing this I cannot confine myself to any country, nor to any time. Science knows no political boundary. The whole world is ours, and telegraphers of every clime are brothers. The lines which stretch from San Francisco over continents and under seas to Japan, New Zealand, and South America include a "million miles of wire," connecting every community of civilised beings on the face of the earth, and endow our profession with a cosmopolitan character. We heartily join with you to-night in commemorating the grand achievements of William Fothergill Cooke and Charles Wheatstone in the year 1837, the very dawn of the electric telegraph. But for them I do not think we would have cable telegraphs to-day, and New York, to-night, would not have witnessed such a notable gathering of British electricians who have adopted this country for their field of labour and residence. In paying this highly-deserved tribute to the two illustrious men who were the first to put in operation a line of telegraph from Euston Station to Camden I do not wish to detract in the most remote degree from those great discoverers and inventors in the same field. Without them the success of Cooke and Wheatstone and later electricians would have been impossible. You will recall the great contributions of Œrsted, Ampère, Steinheil, Franklin, Schilling, Gauss and Weber, Volta, Henry, Morse, Faraday, Dyer, Edward Davy, Cromwell Varley, and many others, nearly all of whom have had the seal of death placed upon their lips, and their records have been left in our hands. We can well afford to be just to their memories.

INCANDESCENT LAMP MANUFACTURE.—XIX.

BY J. SWINBURNE.

Exhausting Continued.

Fig. 21 shows an apparatus for exhausting. The lamp is sealed to the end of a short Sprengel tube, which is bent and sealed into a bulb. Enough mercury is put in the bulb to fill the lamp and leave a few ounces over. The whole is held in such a position as to leave a clear passage between the lamp and the tube with the tap, and the bulb and lamp are then exhausted as well as possible. The tap is then closed, and the apparatus is tipped till the mercury is run into the lamp; by tipping it backwards and forwards the air can be taken from the lamp into the bulb. The last small bubbles that remain can be got into the neck of the tube and the lamp full of mercury can be heated when expansion of the mercury takes them round. Though this looks easy it is troublesome in practice, as the apparatus is unwieldy when full of mercury. The vacuum produced was no better than that of the factory pumps. Unless the carbons are strong and the lamps sealed on so that the loop comes as shown, the mercury breaks the carbon. None of these experiments give promise of commercial success. The question of high vacua and the methods of testing them will be discussed under "Testing."

Fig. 21.

The vacuum for starting the pumps is supplied by mechanical pumps. There should be no difficulty in getting suitable mechanical pumps driven by power; but as a matter of fact it is, as there are no such things in the market, and they have to be specially made.

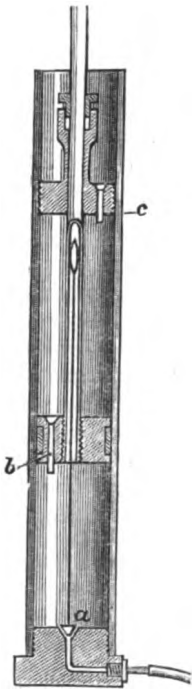

Fig. 22.

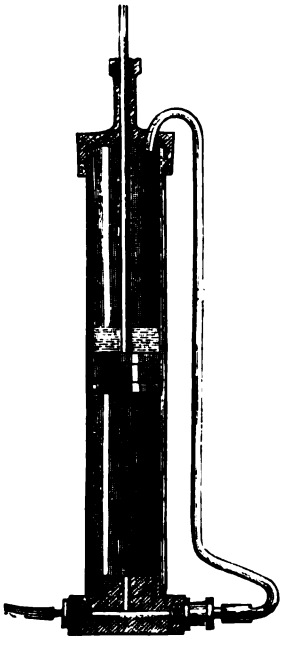

Fig. 23.

The simplest form is the ordinary silk valve pump, or exhausting syringe, as made by opticians. Several of these can be mounted and driven by power by means of a crank and connecting rod.

They are, however, very troublesome to keep in order, as little bits of dirt get under the silk valves, or the pumps get hot or leaky.

Fig 22 is a diagram of the pump that the writer used for some time. It is a modification of the pump used in Carré's hand ice machines.

As the piston rises the valve *a* is lifted by the friction arrangement which passes up the whole piston rod. When the piston begins to descend the valve *a* is closed, and kept shut by the friction of the rod. The piston comes down till it touches the bottom. If the pressure of the air has not already lifted the valve *b* in the piston it is lifted then, as the foot touches the bottom of the pump. The air left in the lower part thus gets out without being compressed by the effort of lifting a valve. When the piston rises the valve *b* shuts and *a* opens. When the piston reaches the top it opens the valve *c*. There is thus a vacuum produced both above and below the piston, so that when the lower chamber discharges through the valve *b* it discharges into a vacuum. These pumps will freeze water by exhausting over sulphuric acid. When driven by power they are apt to get out of order. The pistons cannot be packed with cap leathers, as there is a vacuum on both sides. The space at the top is filled with oil, so that if there is a slight leak the oil is sucked through and does no harm, as it is pumped out again.

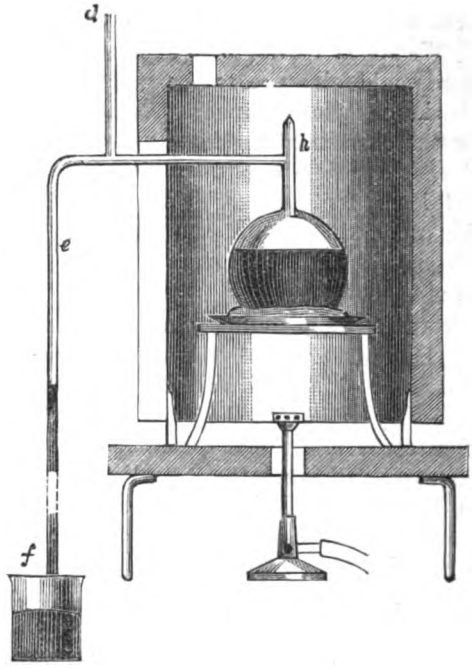

Fig. 24.

Fig. 23 is a diagram of a pump, that does not give such a good vacuum, but is easier to keep in order. The upper chamber is not utilised, and the long neck at the top is merely a guide, not being packed. Two oil-silk valves are arranged at the bottom. They can be screwed out without dismounting the pump. A few ounces of oil travel up and down on the piston; this keeps the pump well lubricated, and leaks through into the lower chambers. The delivery is connected with a pipe, which leads any oil that has leaked through back into the upper part.

The French make curious pumps, in which the cylinder is made of glass carefully ground true. The piston is made of a solid block of brass, turned a trifle smaller than the inside of the cylinder. At first sight one might suppose that such an arrangement would leak, but it does not. Air seems to flow with great difficulty through a very narrow crevice. The writer has used the Deleuil pump, which is made on this principle. This pump is not, however, suitable for factory work, as it is apt to run hot when driven continuously by power. It is unnecessary to describe the Deleuil pump here, as it forms a stock illustration in books on Physics. It is a beautiful piece of laboratory apparatus, and the workmanship is perfect.

Digitized by Google

In Boston a Knowles steam pump was used. When the little brass pumps are used, one is used for every six pumps or so, so that each operator has her own pump, or else there is a pump between two, so that there is less chance of the vacuum being broken in the mercury pumps. With the Knowles pump, of course this practice was not followed, as one pump will work the whole pump room. This pump is used for exhausting the evaporating pans in sugar manufacture. The pump is a cylinder with a packed piston and india rubber or composition valves. The whole is flooded with glycerine, and there is a little adjustable bypass which allows the glycerine to leak slowly into the cylinder. The air and surplus glycerine are ejected every stroke, and the glycerine fills up all the little interstices. A 10in. pump was used for the pump room and a 7in. for the flashing room. The 10in. pump would preserve a fair vacuum even with a $\frac{1}{8}$in. hole open.

The mercury that is swept up from the floor is generally too dirty to be returned to the pumps. If it is merely dusty it may be run through a funnel; but generally that treatment is not sufficient. The methods given in books, such as squeezing it through chamois leather, shaking it up with sugar, or dilute acids, &c., are of no use. The mercury must be distilled. An iron retort, with a long delivery tube, is used. A glass reservoir will do. The retort may be heated by a large Fletcher burner. The receiver should be in water, and the whole must be under a chimney, so that the poisonous vapour cannot escape into the room. The surface of the mercury is covered with half an inch or so of iron filings. If this precaution is neglected the mercury will spurt over into the receiver, causing failure.

The writer much prefers to distil in a vacuum. His apparatus is shown in Fig. 24. It consists of a bulb about 3in. diameter. This is on a tripod stand in a cover like one of those used for keeping the lamps hot, but made of asbestos, not tin, so that any mercury spilled on it does not adhere. It is heated by a Bunsen burner. The tube *d* is connected to a hand mercury pump. The fall tube and the bend above it form the condenser, and the distilled mercury collects in *f*. To fill the bulb the tube *h* is opened. It would not be difficult to arrange a feeding tube so that the process would be continuous, but it is not worth while. A Sprengel fall tube was also tried so as to keep the mercury exhausted better, but it was continually cracking. The apparatus works well, but it must be kept going steadily, else the fall tube gets cold and cracks when some very hot mercury, newly condensed, runs down.

CORRESPONDENCE.

NON-POLAR DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Does not Mr. Snowdon's difficulty arise from a too materialistic conception of the "lines of force"? These have, I take it, no actual existence, but are simply a convention, useful as a graphic means of representing, by their number and direction, the condition of a magnetic field. To a given intensity and direction of magnetic force corresponds a definite distribution of lines of force; and any displacement of the magnet, whereby the intensity or direction of the field is not affected, causes, from the very nature of the lines, no alteration in their position or density. Thus, the rotation of a cylindrical bar magnet about its axis does not induce a current in a *fixed* metallic circuit placed in its field, because the number of lines of force which pass through the circuit are unaltered by the rotation of the magnet, the field being symmetrical about the axis.

So in the Forbes dynamo, the magnetic field is, from the construction of the machine, symmetrical about the axis of rotation, and under fixed conditions of speed, &c., it is also constant; hence the lines of force cannot be said to rotate. The external iron sheathing is, as Mr. Snowdon says, as much armature in a sense as the rotating iron; but it is a stationary armature, and therefore, situated as it is in an invariable field, useless for the production of current. If the machine could be so arranged that this external "armature" were made to revolve as well as the armature proper, a current could, by suitably arranged rubbing contacts, be drawn from it also.—Yours, &c.,

BERNARD P. SCATTERGOOD.

London, July 2nd, 1887.

"NONPOLAR" DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In De la Rive's "Electricity," Vol. I., page 435, there is an account of an interesting experiment which is something like this:—A cylindrical magnet, Fig. 1, is mounted axially in a horizontal position by pivots running in bearings. At its equatorial part a flange is fixed, whose outer edge dips into a mercurial cup as it and the magnet revolve. A similar flange is fixed at the end of the magnet. A sufficient speed is given to the magnet by the crank handle, pulley wheel, and strap. The wires from a galvanometer dip into the two mercurial cups respectively, as shown. By the rotation of the magnet the needle is deflected, proving the existence of a current. The direction of current reverses as the direction of movement is reversed. Now, how is this? De la Rive says the current is produced by the "moving" lines of force cutting that part of the stationary conductor which leads to the galvanometer. But there would be no difficulty in arranging these conductors so as to be practically parallel with the lines of force, and in that case it is difficult to see how the wires could be in any way affected. The question rather appears to be this:—When the magnet revolves does the magnetism, or do the lines of force, revolve with it? If they do, it seems impossible that a current should be generated. If, on the other hand, the magnetism is regarded as separate from the iron, and as a fixed element uncontrolled by the iron, only so far as it is held in it as a mass, then the possibility of a current presents itself at once, for in that case every molecule of iron would cut the magnetism in the most favourable direction for producing a current.

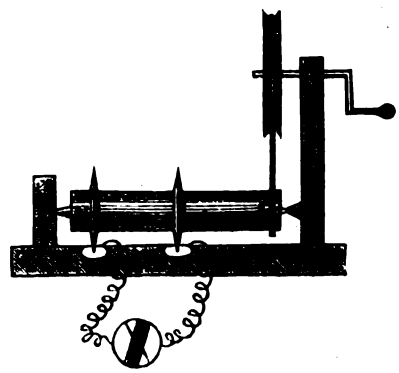

FIG. 1.

In a letter of mine which appeared in your journal on October 13, 1883, I drew an analogy by likening a cylindrical bar magnet to a similarly-shaped vessel containing water. The water was intended to represent magnetism, and, moreover, for convenience, it was supposed to possess lines of force in all respects the same as a bar magnet. If such a cylinder were rotated in the same way as the magnet in the above experiment, it is easy to see that the water and its imaginary lines of force would be held stationary by gravitation. To make the analogy plainer I conveniently ignored the friction of water against the sides. It is evident that the vessel as it revolved would intersect all the lines of force precisely in the same way—according to this theory—as does the revolving magnetised iron in the experiment (Fig. 1).

Faraday carried out a series of experiments involving the same phenomena in quite a different way. As most of your readers are probably acquainted with them I will only just notice them. In his method he employed a jar of mercury, and immersed the magnet in it up to its equatorial part. One collector was applied at this point, and the other at the top of the magnet. Faraday's explanation in this case was that the

Digitized by Google

lines of force passing through the mercury generated the current, so that even he evidently thought that the magnetism was rotated with the magnet, and that a stationary conductor was essential. But we have it in his own words that a definite result was obtained by suspending a magnet by a thread and sharply spinning it round in the air while collectors were properly applied. Surely there was no stationary conductor in this experiment, the action being the same as Fig. 1.

From the simple magnet (Fig. 1) it is but a step to the electro-magnet, when the conditions for my theory would appear to be more favourable, the iron molecules being more magnetically porous, if I may be allowed the expression, and the magnetism more powerful. I think it is generally admitted that the distribution of lines of force in the core of an electro-magnet are longitudinal or parallel to its length. It is convenient in the present case to have the cores of considerable diameter, and if two such electro-magnets be placed side by side and their ends magnetically closed by iron they may be made to form a closed magnetic circuit as shown in Fig. 2. The cores may be capable of rotation in the solenoids, and are formed of discs of iron and copper insulated from each other, but mounted on, and in electrical contact with, the spindles. By connecting all the peripheries of the discs to longitudinal rods the whole of the radial currents developed in the rotating system may be taken off by having contact at the spindle and at the periphery. I have designed a dynamo on this principle in which both the solenoid and core rotate, the wires to the solenoid being led up the spindle, and terminating in flanges immersed in cups of mercury.

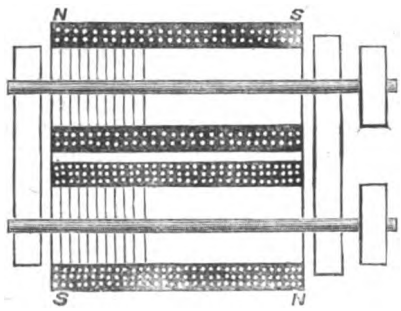

FIG. 2.

It will be seen that there is a difference between the experiments Fig. 1 and Fig. 2. It is this. In the former the chief cause of the current is the outer surface of the magnet intersecting the curved lines of force as they come out of one pole to return to the other pole in air; whilst in Fig. 2 there is practically none of this external magnetism, it being all confined to the cores. With reference to the Forbes dynamo, Mr. Snowdon says:—"What prevents the lines from going round with the armature?" If this theory which I have ventured to propound be correct the question is unnecessary.

The earth has often been compared to a magnet, which it no doubt really is. Query—Does terrestrial magnetism rotate with the earth, or is it fixed in space while the earth rotates through it? At the first glance it would seem that, inasmuch as terrestrial magnetism is probably produced by the earth, it would be expected to rotate with it. But if, with regard to the universe, it were stationary or a fixed element independent of, although caused by, the earth, then, to us, it would appear to move; whilst if it rotated with the earth it would, to us, be stationary. It is only by comparison that we know anything, and it would appear to be necessary, in order to solve this problem, that some other magnetised earth body would have to be taken into account.—Yours, &c.,

London, July 5th, 1887. E. L. VOICE.

ADMIRALTY DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 1st inst. you publish the Admiralty specification recently issued for dynamos and engines, and, commenting thereon, question whether 20°F. is not an almost impracticable limit for the increase of temperature in the machines. An extensive experience with dynamos of most sizes and types enables me to say that the limitation specified is not only impracticable, but, under ordinary conditions of weight, impossible. No dynamos have been yet constructed which will satisfy the conditions named, nor is such construction possible unless the ratio of weight to output far exceeds any limit which the Admiralty would be likely to allow.—Yours, &c.,

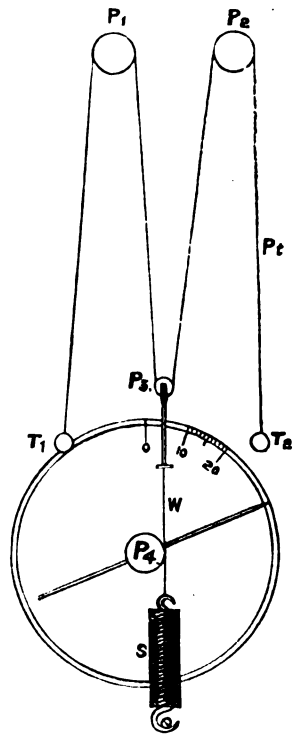
W. B. ESSON.

London, 4th July, 1887.

CARDEW'S VOLTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would some reader having a knowledge of the aforementioned instrument say if the modification as per sketch herewith be practicable? A platinum wire, P*t*, runs from terminal T_1 over pullies P_1 P_2 and P_3 to terminal T_2. A wire,



W, from P_3 to the spring S drives by friction the pulley P_4. Supposing the length of the platinum wire to be 12ft., what gauge would be most suitable? Would it be advisable to increase the traverse of the index finger by a wheel and pinion? The instrument is required to read up to 130 volts or thereabouts. Trusting some reader will oblige.—Yours, &c.,

June 25, 1887. J. H. H.

NOMENCLATURE.—MAC; USE OF *PER* AND *BY*; INTENSITY AND DENSITY; SCIENTICULOMETER; GRAMMATICULIST.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With your permission I would like to add a few remarks on the never-ending subject of nomenclature.

Mac.—I would be obliged by information regarding any reason that can be stated against the use of the word mac as the name of the practical unit of inductance. I mean, of course, a reason that has a backbone in it. I think it possesses to an unrivalled extent all the qualifications, positive and negative, that it is desirable the name of a practical unit should possess.

Use of *Per*.—Coals, twenty shillings per ton, means that the price of a ton of coals is twenty shillings. Now if we divide the price expressed in shillings of any quantity of coals by the

Digitized by Google

quantity expressed in tons, we obtain the number twenty, the price in shillings of a ton. I do not think, however, that the coal purchaser goes through this process, but that he or she goes the other way to work, and on seeing that coals are twenty shillings per ton, thinks immediately of the sum of money twenty shillings, and of the quantity of coals in a ton; and to obtain the price of any quantity of coals, multiplies the number of tons by the price per ton. I am induced to make these very elementary remarks by observing that some writers seem to use *per* to signify "divided by," and nothing more. This practice reaches its climax when the word unit, or the name of the unit itself, is omitted, and it is said, for instance, not that the inductance of a circuit is the momentum per unit current (which is similar to the phrase twenty shillings per ton), but that inductance is momentum per current. If this were all, my remarks would have the usual value of verbal twiddling; but they serve to lead to the real point, which is, the use of *per* in an extended sense. If I say, to avoid circumlocution, that conductivity is the conductance per unit volume, or that resistivity is the resistance per unit volume (not "per volume" observe), I think that what is meant is so immediately obvious that no one thinks of examining whether this use of *per* conforms to the rule, per = divided by. In fact it does not. Yet conductivity is the conductance of a unit volume. I think, therefore, that the use of *per* in the extended sense, which is very convenient, may be permissible.

Use of *By*.—In comparison, it is a very trivial matter, whether we use *by* to signify "divided by" or "multiplied by." My preference is toward the former practice. I would prefer that *into* should signify multiplication. Thus, E by R equals C; and E into C equals activity.

Intensity and Density.—There is usually so marked a physical distinction between a force and the corresponding flux that I think it would be as well to consistently recognise it by applying the word "intensity" to the force and "density" to the flux. This is already generally done as regards forces, and it is becoming common as regards one flux, electric current. In respect to the flux energy-current, which has no force to match, I would speak of its density, because it is not merely nominally, but really a flux.

Surface-integral of a Flux.—Sometimes the distinction between the flux and the force is lost (generally in theoretical investigations in which false conditions are assumed to exist), and then we have surface-integrals of forces. I am, however, convinced that it is well to keep as much as possible to physical ideas, which lead us to line-integrals of forces (intensities of) and surface-integrals of fluxes (densities of).

Scienticulometer.—This word must define itself. I have given a preliminary account of my recent researches with the scienticulometer in a memoir, which is not yet published. Some of my results, however, have been already given by Prof. S. P. Thompson.

I have also endeavoured to apply this instrument to the investigation of a quite new phenomenon, which I may term, provisionally, the learned grammaticulist. Up to the present time, however, I have failed to extract anything but froth, with a parting smack of vulgarity (*see* p. 161). This is disappointing. Froth is excellent in its way, but is rather too insubstantial. As for the other, it is certainly not the proper thing to use, especially for so accomplished a literary critic, who should, I think, endeavour to copy the refined style of Addison and other polite writers.—Yours, &c.,

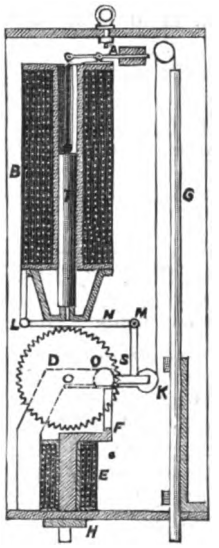
OLIVER HEAVISIDE.

ELECTRIC PORTABLE LAMP.

In connection with our notice of this battery M. Friedländer writes:—"Will you have the extreme kindness to add a few remarks in your next issue. The solution used in my lamp battery is entirely different from any yet known preparation of potassium bichromate. My solution affords one regular and constant current for several hours. The zinc plates always remain amalgamised, and need never be cleaned. When used up to a certain extent the zinc rods can be removed and new ones replaced by anyone in less than five minutes. One principal advantage with my new lamp is the simplicity. Recharging is as simple and easy as with an ordinary petroleum lamp. The lamp can be lit by simply turning the knob, because the lamp can be kept with battery charged any length of time, and be at hand any moment. The light can be regulated from 2 to 4 candle-power."

THE HARDT ARC LAMP.

The adjoining figure shows the mechanism of an arc lamp designed by M. Hardt, and described in *La Lumière Electrique*. B is a solenoid connected in shunt, and containing a hollow core, T, which carries at its lower extremity a catch which engages with the teeth of an iron wheel, D.



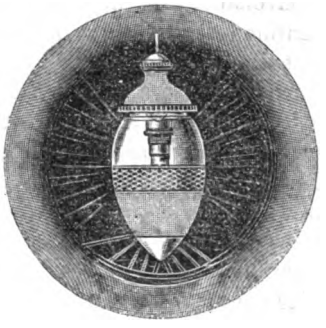
E is an electro magnet in series in the main circuit. This magnet has an armature in the form of a bent lever, F, which is pivoted at O, and is pulled down when the current is switched on. This lever carries the pulley K, over which passes the cord which supports the upper carbon holder G. The piece M is connected to F, and the lever N is articulated at M and at L. H is the lower carbon holder. The cord supporting the upper holder is wound around the axis of the wheel D.

The carbons being in contact, when the circuit is closed the lever F is pulled down by the magnet E and the upper carbon is raised, striking the arc. At the same time the lever N is also pulled down, and the core T, which was previously upheld by N, engages with the toothed wheel D, and checks its rotation.

As the arc elongates the solenoid B is more powerfully excited, until at length the core T is again raised and the wheel released. The movement is retarded by means of a lever and counterpoise connected with the core. When T is thus raised the weight of the upper carbon and holder is sufficient to cause the rotation of the wheel D and the consequent shortening of the arc. This, however, is prevented from taking place too rapidly by the braking effect of the magnet E upon the iron wheel.

LEA'S ORNAMENTAL GLOBES FOR INCANDESCENT LAMPS.

Messrs. Fowler, Lancaster and Co. are introducing a globe for enclosing incandescent lamps, which is represented in the adjoining figure. Of course, the object of such an attachment is to conceal the filament itself from the eye, while intercepting the light as little as possible. Both the globe and its cover are made entirely



of glass, and there are no metallic rims or screws to work loose, the connection being of an elastic character. The method of attachment adopted relieves the electrical connections of the lamp-holder from the weight of the globe. So far as can be judged from the figure, this globe will probably strike most of our readers as being particularly well designed from the æsthetic point of view.

ENTOMOLOGICAL ADVANTAGES OF ELECTRIC LIGHTING.—It has been observed in Ottawa, Canada, that the introduction of the electric light in street illumination has facilitated the collection of entomological specimens, particularly of rare species, as insects of all kinds are attracted to the lamps in large numbers.

THE BANQUET TO PROF. TYNDALL.

The large and distinguished gathering at Willis's Rooms last week to do honour to Prof. TYNDALL on his retirement from the Chair of Natural Philosophy in the Royal Institution was an event which, although in the highest degree complimentary to him personally, may also be taken as a notable recognition of scientific research which he has so long and so brilliantly represented. Hardly less so are the ungrudging praises bestowed upon his career by the daily press. Not so very many years ago neither the banquet nor the newspaper articles would have been possible. Prof. TYNDALL has generally worked upon contested ground; and it has been his lot in times past to come in conflict with the most cherished convictions of his countrymen. The recollection of these feuds, however, has been wiped away, partly no doubt by his own singular powers of persuasion, but partly also by the spread of scientific knowledge which has reconciled the world to his teaching by making it less novel and startling. Formerly he was pointed at as a dangerous man, and a warning example of what science was tending to; to-day he is the honoured guest of all shades of politics and almost all shades of religious belief. If the strictly theological element was not there, it was more because its presence might have been misunderstood than from any prejudice against science, or any want of respect for one of its greatest modern exponents.

Prof. TYNDALL'S own speech on the occasion referred to has naturally formed the chief subject of public comment, and we need not go over the same ground here. It was a lucid and eloquent discourse, and a fine example of that literary talent which has done so much to make science in these days a popular and attractive study. But, as bearing on our remarks above, the other speeches which followed were equally noteworthy and instructive. There was the speech of the Statesman in the person of Lord DERBY, and that of the Man of Letters represented by Lord LYTTON. "The Public Services in Relation to Science" was handled by Sir LYON PLAYFAIR, who, if not distinguished as a public servant or a man of science, is a sufficiently conspicuous representative of the Politician. We do not know in which capacity it was that he deplored the loose connection that existed between Science and the Government; but if he spoke as a politician he got very little countenance in the person of Lord DERBY, who replied on behalf of the State. With regard to the common complaint that our statesmen have done so little for science, Lord DERBY retorted that "they had done the best they could for it—they had let it alone; they have not corrupted it by their intrigues, nor vulgarised it by their squabbles; and they being what they are, and science being what it is, that is probably the best service they could have rendered it."

Now, in this blunt expression of the practical statesman we should imagine Prof. TYNDALL would himself concur. Possibly Sir LYON PLAYFAIR meant technical education, while Lord DERBY had in his mind the kind of education represented by their illustrious guest. Certainly Prof. TYNDALL'S own language does not lend itself readily to the State patronage of science. He extols the pursuit of truth for its own sake, and the steady application to scientific research, without the least regard to its utilitarian aspect, as the highest vocation to which a man can devote himself; and it is pretty obvious that you cannot claim the merit and seek the reward at the same time. We say seek it, because, of course, in certain circumstances, it may be the duty and the highest privilege of the State to confer that which is not sought. An instance of this kind was furnished in the career of FARADAY, whom we feel sure Lord DERBY would not have "let alone" in the sense of leaving him unfriended and penniless. Probably what the practical politician means is that it will never do to make Science the object of political patronage; and that this is certainly a danger which would be incurred by making the relations between Science and the State less "loose" than they are at present.

Perhaps the advocacy of State patronage is rendered rather more than less difficult by the transcendental aims and motives ascribed to the pursuit of science by men like Prof. TYNDALL. We are not for a moment questioning their sincerity; on the contrary, we are confident that their ruling motive is as far removed from selfishness as any human passion can be. But it is clearly not a cry upon which one can "appeal to the country," though an excellent one for an appeal to the conscience. "I do not know and I do not care whether my discoveries are, or may ever be, of any use," says the ideal philosopher, according to Prof. TYNDALL. "Very good," remarks the common-place world; "you satisfy your notion of duty, you cultivate the special aptitudes which you are conscious of possessing, and you gratify your thirst for knowledge; but you are by no means sure or anxious we should get any benefit by your industry. That being so, really the best thing we can do is to 'let you alone;' for if we were to endow you we should run two serious risks, the one of corrupting you, the other of paying for what, according to your own showing, may be of no value." *The Times* is evidently per-

Digitized by Google

plexed by the problem here presented by this lofty standpoint of science, and solves it in the usual way, by ascribing to science its highest value as an educational instrument. But surely this is reducing it to the level of mathematics or the study of the classics. Natural philosophy may be superior to either of these as a trainer of the mind; but this is not the matter in question. The votaries of scientific research have not followed it as a lifelong vocation merely in order to train their minds. If that were the case their education would be exclusively their own affair; and we instinctively feel that it is not exclusively theirs, but is ours as much as, and even more, than theirs. In our judgment it would be well to drop, in some degree, this talk about superior motives, and dwell a little more upon the superiority of results. The motives in this cynical and time-serving age may be called in question; but the utilitarian side of scientific research can be confidently asserted by its professors, and is not likely to be contradicted by the non-scientific world at large. The world, indeed, feels itself profoundly indebted to the class of man of whom Prof. TYNDALL is a shining example; but the debt will be more cheerfully paid if his services, rather than his virtues, are made the subject of laudation.

EFFICIENCY TESTS OF A GAULARD AND GIBBS TRANSFORMER.

BY P. CARDEW, CAPTAIN R.E.

From *Industries*, July 1.

The excellent articles by Mr. Kapp on the determination of the lag of primary current behind impressed E.M.F., and of magnetisation behind primary current in a transformer, have been of great service to me, as I happened just at the time that they appeared to be engaged in determining the efficiency of one of these instruments, specially wound and submitted for test by the company connected with Messrs. Gaulard and Gibbs. I was preparing to wrestle with the problem myself when I found this labour saved by the articles mentioned, and as a slight return for this benefit I give herewith the tests taken, with the lags worked out and expressed as angles, and the external efficiency deduced. The tests do not pretend to anything like exact accuracy, as time and the present importance of the question to the War Department did not permit of elaborate precautions being taken. Nevertheless, and in spite of considerable variation in all the quantities measured, the resultant efficiencies are very close, and the sum of the angles ϕ and ψ still more strikingly close in all the tests. The turns of the primary and secondary conductors were to each other in the proportion of 4:5, which obviously would not be suitable for a practical instrument, but which was very convenient for our means of measuring. The weight of the transformer was about 90lb.

The angle ϕ is the lag of primary current behind E.M.F., as used by Mr. Kapp in discussing a single magnetic coil. I think it is a pity that he called this ψ in discussing a transformer; ψ is the lag of magnetisation behind primary current. The efficiency is

$$\frac{\text{Secondary current} \times \text{secondary E.M.F.}}{\text{Primary current} \times \text{primary E.M.F.} \times \cos\phi}$$

The resistance of the two coils was: Primary, ·023ω; secondary, ·036ω. This indicates equal mass of each conductor, in which case the resistances should be to each other in the proportion of the square of the conversion factor, not in the simple proportion, as I think I have seen it stated. The calculated external efficiencies are certainly too high, for the following simple reason, as pointed out by Mr. Kapp, viz., whatever power is absorbed by the iron core should be expressed as current × E.M.F.; the current must oppose the magnetisation, and its ampere turns should be added to those of the secondary current in calculating ψ, making ψ greater and ϕ less than as now calculated. This, of course, will make the number of watts in the primary somewhat higher. It is quite hopeless, I think, to attempt this correction; but, from estimating the radiation from the core, I should put the power wasted at full load at about 2½ per cent., leaving an efficiency of conversion of 97·5 per cent.

However this may be, I consider the results undoubtedly show a very high efficiency for these transformers, and I must say that, in my opinion, great credit is due to Messrs. Gaulard and Gibbs and the company connected with them for what they have done in the face of every sort of discouragement to perfect the system, which I am convinced has a great future before it.

The interchange of energy between the transformer and the supplying circuit is a curious phenomenon. When ϕ is appreciable the transformer begins to return energy during a portion of each alternation, and when $\phi = \frac{\pi}{2}$ the energy given to the transformer during one quarter of an alternation is returned during the next quarter, except what is exhausted in heating the conductor. There is a sort of ebb and flow of tide enduring in the case of the last experiment but one, for about $\frac{1}{600}$th second, and only a little leaks out each time. In this experiment the calculated primary watts are 55·4, of which 40·57

* Primary volts probably read too high. † Estimated current in voltmeter.

NOTE.—The dynamometers were very insensitive for the currents used, it being considered desirable to avoid self-induction in them.

Digitized by Google

are absorbed in the primary coil, and 15·4 in the secondary circuit, so that in this case we get an apparent efficiency of conversion of $\frac{55·97}{55·4}$, just over 100 per cent., but of course this should be reduced on account of the power absorbed by the iron core. The fact that the primary current absolutely rose to a higher value in this experiment as compared with the previous one is very curious.

The primary circuit was connected to a 32-magnet Wilde machine, the secondary circuit to 50 candle-power 60-volt lamps. In the first series the volts at machine were maintained constant by the engine driver altering his speed to suit the load, and the tests were taken on one Siemens electro-dynamometer and one Cardew voltmeter, by rapidly changing the instruments from one circuit to the other. In the second series an attempt was made to keep the speed constant by altering the strength of field in the machine; but as no suitable rheostat was available, and the engine was not governed this could not be exactly effected, and the volts on the primary circuit show considerable variation. Two dynamometers and two voltmeters, however, were used, so that absolutely simultaneous readings were secured. In the third series no attempt was made to keep any value constant, but simultaneous readings were taken. The angle ϕ is the lag of primary current behind impressed E.M.F., ψ that of magnetisation behind primary current; their sum, as shown, is in all cases nearly 90°.

ON THE SUPPOSED "NEW FORCE."

At one of the May meetings of the Royal Society Mr. Crookes discussed the supposed "New Force" of M. J. Thore, whose experiments led him to believe in the existence of a new force inherent in the human organism. M. Thore suspends a small cylinder of ivory by a fibre of cocoon silk forming a small pendulum which hangs freely over the centre of a table. The cylinder having become motionless, M. Thore brings a second cylinder, called the "pillar," about a millimetre from the first cylinder, when the latter begins to rotate clockwise if the pillar is on the left, and counter clockwise if the pillar is on the right of the cylinder. The observer is supposed to face the cylinder and pillar. M. Thore says that the rotation is independent of the nature of the cylinders, of their mass, or the dimensions of the pillar; light, heat, electricity, magnetism, gravity, and air currents, he says, are also inadequate to explain the phenomena.

Mr. Crookes repeated M. Thore's experiments, and came to the conclusion that the action is one of radiation from the face or other warm body in front of the apparatus, and that there is nothing special in the human organism beyond the heat it radiates to produce rotation of the cylinder.

Mr. Crookes's experimental results were sent to M. Thore, who replied that the dynamical explanation was not sufficient to account for more than a few of the facts he describes, and saying that he "persists in still believing that this force emanates from the observer, or else that the observer is the indispensable intermediary for its manifestation." In reply to this Mr. Crookes states that although he experimented in an enclosed space, while M. Thore experimented in free air, and thinks that enclosure may almost or quite suppress force, he has verified nearly all M. Thore's facts of rotation by his method. He had verified the facts of rotation when working in the free air of a large room, and it was only when he found the delicacy of the observations was impeded by draughts and currents that screens were put round the apparatus.

It may be wondered why we mention experiments which are not directly electrical, but as—as will have been seen from our correspondence columns—Dr. Shettle maintains that the results obtained are directly due to electric or magnetic influence, and not to heat radiations, our readers may be perhaps interested in obtaining from Dr. Shettle a brief account of the experiments he has carried out in this direction.

NOTE ON THE ELECTRO-DEPOSITION OF ALLOYS, AND ON THE ELECTROMOTIVE FORCES OF METALS IN CYANIDE SOLUTIONS.*

BY SILVANUS P. THOMPSON, D.SC., B.A.

It is known that the electro-deposition of such alloys as brass, bronze, and German silver is not practicable from mixed solutions of the sulphates or chlorides of the constituent metals, but can be accomplished by using cyanide solutions or neutral solutions containing cyanide of potassium in excess, thereby apparently departing from the law of Berzelius, that out of a solution of mixed metals the least electro-positive metal is deposited first.

To ascertain the cause of these facts the author has investigated—

(*a*) The electromotive forces of a number of metals in aqueous solution of cyanide of potassium.

(*b*) The dependence of these electromotive forces, in particular those of copper and zinc, upon the degree of concentration of the solution.

(*c*) The variation of the electromotive forces of copper and zinc in a standard solution of cyanide of potassium at varying temperatures.

(*d*) The electromotive forces of zinc and copper in a "brassing" solution, consisting of the mixed cyanides of zinc and copper, having excess of cyanide of potassium present, and their variation at different temperatures.

It is found that the effect of higher concentration of the cyanide solutions is invariably to increase the electromotive force of copper more than it increases that of zinc.

In a cold dilute solution of cyanide of potassium the electromotive force of zinc against carbon is 1·158 volt, while that of copper against carbon is 0·948 volt, or zinc is 0·210 volt higher than copper. In a boiling saturated solution of cyanide of potassium, the electromotive force of zinc against carbon is 0·768 volt, and that of copper against carbon is 1·300 volt; or copper is 0·532 volt higher than zinc.

It is therefore possible to construct a voltaic battery containing one metal only, namely, copper, and one electrolyte only, namely, an aqueous solution of cyanide of potassium, kept hot at the anode and cold at the cathode of the cell.

In cyanide solutions, containing about the following number of grms. of cyanide to the litre, the following were the electromotive forces observed with a carbon cathode:—

Solution containing per litre 99·4 grms.		191·4 grms.		1·18 grms.	
		Metals at 18° C.			
Zinc	1·520	Copper	1·434	Zinc	1·13
Copper	1·425	Zinc	1·401	Brass	0·58
Brass	1 400	Brass	1·315	German silver	0·50
German silver	1 05	German silver	0 936	Lead	0·44
Gold	0·885	Gold	0·834	Copper	0·39
Silver	0 845	Silver	0·810	Silver	0·39
Lead	0 64	Lead	0·609	Gold	0·34
Iron	0·47	Iron	0 181	Steel	0 30
Steel	0·44	Steel	0·161	Iron	0 30
Platinum	0 27	Platinum	0·017	Platinum	0 14
Carbon	0	Carbon	0	Carbon	0

Several of the metals exhibit maximum electromotive force at an intermediate concentration.

The following figures were obtained for zinc and copper in solutions of cyanide of varying strengths at 17° C.:—

Grms. per litre.	E.M.F. zinc.	E.M.F. copper.	Difference Z—C.
2·9	1·158	0·948	+0·210
5·9	1·167	0·967	+0·2 0
11 2	1·184	1·018	+0 166
23·8	1·221	1·058	+0·163
47·7	1·269	1·130	+0·139
95·5	1·303	1 220	+0 080
191·1	1 355	1·360	−0·005

In a mixed solution of cyanides of zinc and copper there is a neutral condition where the electromotive forces of zinc and copper are equal, and this neutral condition varies with the relative amounts of metal present, with the concentration of the solution, and with the temperature. The neutral temperature for a solution of given concentration is lowered by adding cyanide of potassium, and is raised by adding ammonia. The neutral point, however, is not well defined, the behaviour of copper being very uncertain; in general the electromotive force of clean copper in a cyanide solution rises, in some cases, as much as 0·06 volt, in a few seconds after immersion, but is rapidly though temporarily lowered on agitation.

Since the degree of concentration of the solution greatly affects the electromotive force of the metal, and since, in the act of deposition of a metal from its solution, the concentration of the liquid around the cathode is reduced, owing to slowness of diffusion, it follows that in electro-deposition the counter electromotive force at the cathode will vary with the rate at which metal is being deposited, and will therefore vary with the current-density employed. And since, moreover, the variations in electromotive force due to differences of concentration are greater for copper than for zinc, it follows that in the deposition of brass from a mixed solution of cyanides of a medium concentration, in which zinc is slightly more electro-positive than copper, there will be a certain density of current with which the metals will be deposited in nearly equal quantities, while for weaker current densities the less electro-

* Paper read before the Royal Society, June 16, 1887.

Digitized by Google

positive metal will be deposited in excess, and for stronger current densities the more electro-positive metal will be deposited in excess.

Hence, to variations in the concentration of the electrolyte near the cathode are due the departures, observed with all currents except weak ones, from the law that out of a solution of mixed metals the least electro-positive is deposited first.

THE DRIVING OF DYNAMOS WITH VERY SHORT BELTS.*

BY PROFS. W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

When fast-speed machines, such as dynamos, are driven in the usual way by belting, there is a certain waste of power in overcoming the friction that is set up between the driven spindle and its bearings by the tensions necessary to be given to the two sides of the belt to produce the required grip on the small driven pulley. This waste of power is usually kept small by using a long belt and putting the dynamo at a considerable distance from the large driving pulley, and thus obtaining a large angle of contact with the belt with the small driven pulley. But such an arrangement is very inconvenient to employ on board ship or in the guard's van of a railway train or elsewhere, when the space is confined, and a short belt would always be employed were it not that the small angle of contact of the belt with the driven pulley, that would be produced if the small pulley was put close to the large driving one, would necessitate the tension on the belt being large. And this large tension would cause considerable pressure on the bearings, leading to a considerable waste of power in overcoming friction; further, the belt would be much stretched, requiring constant adjustment of the dynamo to tighten it to avoid slip. And further, the occasional stretching of the belt produced by atmospheric changes would make the belt slip were the tension when the belt shortens again not far greater than is necessary for driving purposes. Hence the average tension of such a belt must be made to far exceed what a simple calculation of the necessary driving tensions would give, and the waste of power is in consequence also much in

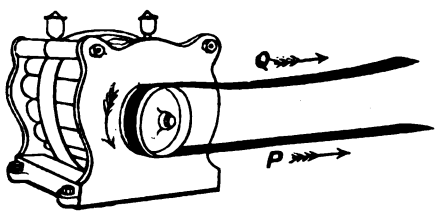

FIG. 1.

excess. Indeed, this is the reason why belting is usually placed more or less horizontal, and why long belts are employed with the upper side the slack side, so as to introduce a weight compensation, as seen in Fig. 1.

Similar difficulties occur when an electro-motor, or other fast-speed motor, is used to drive machinery by means of belting.

Very many plans have been tried of overcoming this difficulty. For example, to increase the angle of contact of the short belt with the small driven pulley, and to keep the belt tight, Messrs. Mather and Platt used a large tightening pulley with their compact engine and dynamo at the Inventions Exhibition, and also now at the Manchester Exhibition.

In transmitting power from an ordinary steam engine to a dynamo, or from an electro-motor to a tool, we have to gear a slowly and a fast rotating shaft, and the problem of doing this in a limited space, and with small loss of power in overcoming friction, has led to the many forms of "*friction gearing*" that have from time to time been devised. Indeed, one part of the joint work in telpherage carried out by the late Prof. Fleeming Jenkin and ourselves was the designing of many modifications of such friction gearing, or, as it has been called, "*nest gearing*," for enabling power to be transmitted between a slowly and fast rotating shaft by means of a *pure couple without side thrust*. To enter into even a short description of these many forms would take up too much of your time; but we may mention that those interested in the subject will find descriptions of some of them in papers read before the Society of Arts and the British Association. The great objection to the employment of such friction gearing is the expense of construction, since adjustments have to be introduced to take up the wear of the rolling pulleys, which is considerable; hence, in spite of the ingenuity of friction gearing, from a mechanical point of view, and of the captivation it has for those who are concerned with this problem of transmitting power between slowly and fast rotating shafts, it has not come into general use.

You are probably familiar with the form of friction gearing employed by Messrs. Siemens† for driving dynamos. The dynamo is balanced so as to turn on an axis at right angles to the axis of rotation of the armature and the dynamo pulley; the pulley is made of compressed paper, and rests on the top of the fly-wheel of the engine. The arrangement is good, since the force pressing the pulley against the rim of the fly-wheel is not all transmitted through the bearings, but is partly furnished by the weight of the dynamo pulley. But this form of friction gearing has the following objections: First, the paper pulley has to be constructed in a very special way, under hydraulic pressure, and is necessarily much more expensive than an ordinary cast-iron pulley. Secondly, the fly-wheel of an ordinary engine cannot be employed without having first its rim turned up true. Thirdly, the axes of rotation of the armature and fly-wheel must be placed accurately parallel to one another, otherwise there is a grinding action at the surface of the paper wheel, which destroys its surface. Next, it is a mistake to place the dynamo so that the paper pulley rests on the very top of the fly-wheel, since with this arrangement there is necessarily a side

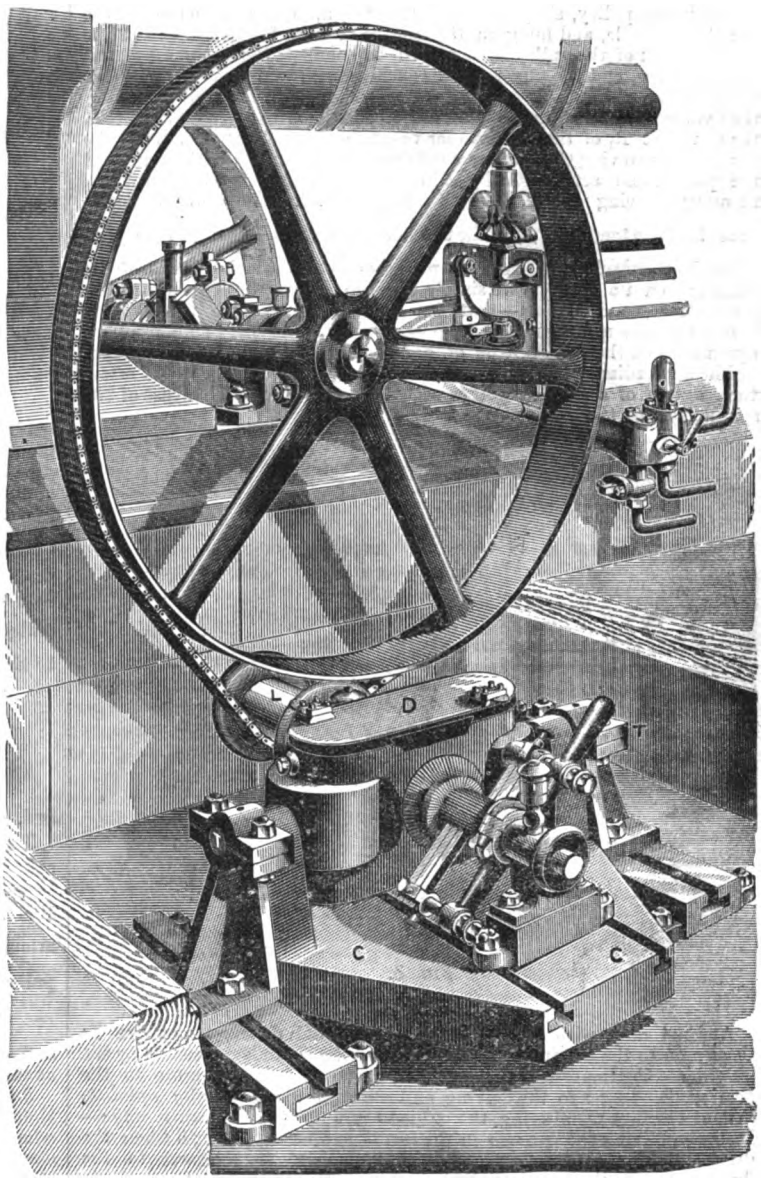

FIG. 2.

thrust on the bearings, and the power wasted in friction at the bearings cannot be made as small as is possible. And lastly, we are told by users of this form of gearing that there is a tendency for the whole framework supporting the dynamo to get into a state of vibration. The result is that this method is not one by means of which any dynamo can be arranged so as to be driven directly by the fly-wheel of any engine, and is only employed when the engine and dynamo are constructed so as to form practically one piece of machinery.

A form of gearing employed for driving a dynamo with a gas engine may be seen in the city, and at first sight this might appear to be merely the inversion of the gearing just described, because in this latter the pulley of the dynamo, instead of resting on the top of the engine fly-wheel, is pressed up against it below. But although this makes a less cumbersome arrangement, there is not any saving in the power wasted in friction at the bearings of the armature spindle, as there is in the Siemens gearing, since with the latter arrangement a force equal to the sum of the weight of the pulley and the force pressing the pulley up against the fly-

* Paper read before the Society of Telegraph-Engineers and Electricians, April 28, 1887.

† Since the writing of this paper we have learnt that this ingenious method of driving is due to Mr. Raworth.

Digitized by Google

wheel has to be transmitted through the bearings. It is not, therefore, necessary to consider this form of gearing in detail, since it is not one that saves any portion of the waste of power in the friction at the bearings.

We now come to the new method which we wish to bring before you, and which consists in hanging the dynamo pulley L from a short belt passing round the engine fly-wheel F, as seen in Fig. 2, the belt being only just long enough to embrace the fly-wheel and dynamo pulley without the two being brought into contact. The dynamo D, as in the previous case, is supported so as to turn round an axis at right angles to the axis of rotation of the armature, and the method of fixing the dynamo is as follows :—The pulley is removed from the spindle S, and the dynamo is fixed in a cradle, C C, turning on trunnions, T T, in such a position that the dynamo and cradle just balance. Then, if p_1 p_2 be the pressures of the armature spindle on the two bearings B_1 B_1, respectively nearer to and further from the pulley end of the dynamo,

$$p_1 + p_2 = \text{weight of armature, commutator, and spindle.}$$

The pulley, which is heavier than an ordinary dynamo pulley, but, like an ordinary pulley, simply made of cast-iron, is now keyed on to the armature spindle, and hung in the belt, as seen in the figure, and as the entire weight of the pulley is supported by the belt, the dynamo by itself still balances, and the pressures on the bearings are simply p_1 and p_2, as before. The pulley L_1 is made of such a weight, and the cradle carrying the dynamo is placed in such a position relatively to the fly-wheel, that the resultant R_1 of the tensions for the two sides of the belt, when the dynamo is receiving the maximum driving power, is equal to the weight of the pulley, and acts vertically through its centre, together with the necessary driving couple, V V, as seen in Fig. 3. The horizontal components of the tensions P, Q in the two sides of the belt $\frac{A B}{B C}$ are in equilibrium by themselves, so that the pressures exerted by the spindle of the armature on its bearings are simply equal to the weight of the armature, commutator, and spindle—that is, are even less when the dynamo is receiving the maximum driving power than in the case of an ordinary dynamo when the armature is *at rest*, since our form of belt gearing, unlike any ordinary belt, communicates *simply a pure couple* to the armature, instead of a couple together with a smaller or greater thrust of the spindle against the bearings.

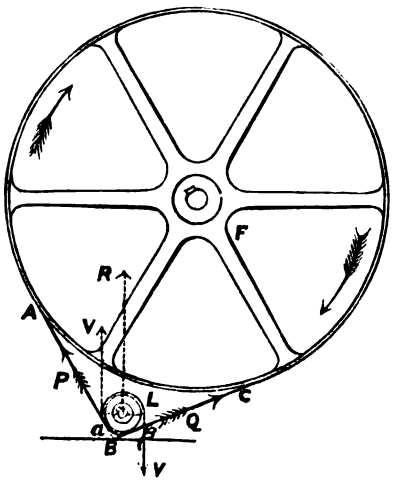

FIG. 3.

And not only with this mode of driving need no extra pressure be thrown on to the bearings, but the pressure that is produced merely by the weight of the armature can be diminished. In fact, the pressure on the bearing, B_1, nearer to the driving pulley *can be made actually equal to nought* by slightly altering the adjustments in the following way :—Instead of fixing the dynamo in the cradle so that it balances when the driving pulley is removed, fix the dynamo a little nearer to the fly-wheel, so that the pulley end of the dynamo is a little the heavier, and move the cradle C C a corresponding distance away from the fly-wheels, so that the pulley, when keyed on to the armature spindle, and the fly-wheel are properly in line. Then the tensions in the two sides of the belt are balanced, not merely by the weight of the pulley, but by this weight plus any portion, or the whole, of p_1 depending on the exact position in which the dynamo has been fixed on the cradle. Hence the weight of the pulley may be made smaller by an amount equal to the portion of the pressure p_1 which is carried by the belt, and the pressure on the bearing B_1 nearer the pulley, which, with an ordinary dynamo, is by far the larger, can, with this arrangement, be made as small as we like, or even nought, whether the armature be at rest or the dynamo be producing its maximum power. The pressure on the other bearing, B_2, will of course never exceed p_2, which is usually equal to about half the weight of the armature, commutator, and spindle. And, since the diameter of the spindle on the side farther away from the pulley can be made comparatively small, as power is not transmitted through it, the power spent in overcoming friction at this bearing, B_2, will be trifling. Hence the total waste of power at the bearings can be made practically nought by employing this form of belt gearing.

And further, this gearing has the following advantages not possessed by the Siemens gearing :—

1. There is no paper pulley to be constructed and to wear out.
2. The rim of the engine fly-wheel need not be specially turned up.
3. The axes of rotation of the armature and fly-wheel need not be accurately parallel, as the yielding of the belt allows for want of perfect parallelism.
4. The cradle of the dynamo is low down, and therefore can be made steady.

It is also clear that any slight stretching of the belt will not cause it to become slack, since the only effect will be to lower the pulley slightly, and incline the axis of the armature to the horizontal.

To further illustrate this method of belt gearing we give the actual calculations made for determining the proper weight to give to the dynamo pulley, and the proper position in which to place the dynamo, which is now being driven by a short belt at the central institution.

The four things to be determined are—

1. Proper size of dynamo pulley.
2. Proper weight of dynamo pulley.
3. Proper distance to place axis of armature below axis of fly-wheel.
4. Proper distance to place axis of armature to one side of axis of fly-wheel.

1. The dynamo in question requires about 6 horse-power when running at 1,600 revolutions per minute, and when giving out the safe maximum number of watts. The fly-wheel of the engine is 4ft. 11in. in diameter, and runs at 180 revolutions per minute; therefore, in order that the dynamo may be driven by a belt directly from the fly-wheel, the diameter of the dynamo pulley must be

$$\frac{180}{1600} \times 4' 11'', \text{ or } 6\tfrac{3}{4}\text{in.}$$

2. Let P and Q be the tensions, in pounds, of the belt on the tight and slack sides respectively, when the dynamo is receiving 6 horse-power, then

$$(P - Q) \times 1{,}600 \times \pi \times \frac{53}{8 \times 12} = 6 \times 33{,}000,$$

$$\text{or } P - Q = 71{\cdot}3, \text{ say } 72\text{lbs.}$$

If the rim of the dynamo pulley were in actual contact with the rim of the fly-wheel, it is easy to show that the angle between the belt on the two sides of the pulley would be 105deg. The pulley and fly-wheel must not touch, since they would be moving in opposite directions at the place of contact. But in order to make the arrangement compact it is desirable that the pulley should be as near the fly-wheel as it conveniently can be without touching; therefore let us take 100deg. as the angle that the belt shall make on the two sides of the pulley. Then, since the belt makes a tangent with the pulley, the arc of contact of the belt with the rim of the pulley must be 180deg. – 100deg.—that is 80 deg., or $\frac{4}{9}\pi$. Therefore, if P be the tension of the tight side of the belt, and Q that of the slack side,

$$\frac{P}{Q} = \epsilon^{0{\cdot}4 \times \frac{4}{9}\pi}$$

$$\therefore \quad P = (P - Q)\ \frac{\epsilon^{0{\cdot}1778\pi}}{\epsilon^{0{\cdot}1778\pi} - 1},$$

and, as just shown, P – Q equals 72lb.

Therefore $P = 169\text{lb.}$,

and $Q = 97\text{lb.}$

By the triangle of forces it is seen that the resultant of P and Q equals 180lb. Therefore, if the dynamo is so placed that half the weight of the armature and spindle, which is $\frac{94}{2}$lb., is borne by the belt as well as the pulley itself, the weight of the pulley must equal

$$180 - \frac{94}{2}, \text{ or } 133\text{lb.},$$

and a pulley of this weight was cast, and is at present in use on the dynamo at the Central Institution.

3 and 4. To determine the position in which the axis of the armature should be placed below and to one side of the axis of rotation of the fly-wheel, we have the condition that the horizontal components of the tensions on the two sides of the belt should be equal and opposite in order that there may be no side thrust. Hence, if α and β be the angles that the two sides of the belt make with the horizontal (Fig. 3),

$$P \cos \alpha = Q \cos \beta,$$

$$\text{or} \quad \frac{\cos \alpha}{\cos \beta} = \frac{Q}{P} = 0{\cdot}574.$$

And since the angle between the two sides of the belt is 100°,

$$\therefore \alpha + \beta + 100° = 180°,$$

$$\text{or} \quad \beta = 80° - \alpha,$$

$$\therefore \cos \alpha = 0{\cdot}574 \cos (80° - \alpha),$$

and expanding we have

$$\tan \alpha = \frac{1 - 0{\cdot}574 \cos 80°}{0{\cdot}574 \sin 80°} = 1{\cdot}59,$$

$$\therefore \quad \alpha = 57° 50',$$

$$\text{and} \quad \beta = 22° 10'.$$

Plotting these results to scale it is found that the distance of the centre of the dynamo pulley below the centre of the fly-wheel must be 2ft. 8½in.,

Digitized by Google

and the distance sideways 10½in., a result which is also confirmed by calculation. And this is the position in which the dynamo was placed some six months ago.

As a proof of our conservative familiarity with the ordinary method of driving a dynamo, instead of with the principles of belt gearing, the first remark made by almost everyone who has seen the new gearing is that the belt must slip very much. As a matter of fact, however, so far from there being any serious slip, experiment shows that the dynamo, when giving out its maximum power, rotates a little faster than the calculation makes it, due of course to the diameters of the fly-wheel and pulley not being exactly as stated in the calculation.

We need not dwell here on the fact that ropes may be used instead of belts. Again, when a number of dynamos have to be driven from one fly-wheel in a confined space, one driving belt may be used for all, and, by means of guide pulleys, arranged so that each dynamo pulley lies on the belt between two guide pulleys, the part of the belt on one side of each dynamo-pulley being nearly horizontal and on the other side nearly vertical.

THE MEASUREMENT OF SELF-INDUCTION, MUTUAL INDUCTION, AND CAPACITY.

BY W. E. SUMPNER, B.SC.

(Continued from page 172.)

General Formula.

The following method of treating the general problem of a network of conductors will be found simpler in working than that of Clerk-Maxwell, who (Vol. I., sec. 280) expresses potentials in terms of the conductivities of the different branches:

Let E_x denote the E.M.F. in any branch x of the network.
" C_x " current " " "
" L_x " coefficient of self-induction in any branch x of the network.
" M_{xy} " coefficient of mutual induction between the branches x and y of the network.
" x " resistance of the branch x.
" F_{xy} " ratio of a definite electromotive force in the branch x to the steady current in the branch y produced by it. This ratio depends only on the resistances of the network branches.

Let the positive direction of any branch be defined as that direction in which an electromotive force must act in that branch to produce a current in a particular direction in a particular branch, and let the current or E.M.F. of a branch be considered positive when acting in the positive direction of the branch.

It follows, from Maxwell (Vol. I., sec. 281), that

$$R_{xy} = + R_{yx},$$

and also that the above definition is equivalent to the following:—

The positive direction of any branch is the direction of the current produced in it by a positive electromotive force in a *particular* branch.

The kinetic energy due to the mutual induction of the branches x and y is

$$M_{xy} C_x C_y.$$

If the electromotive forces in the network tend to increase either of the currents C_x or C_y there must be created an opposing electromotive force in the other branch, since otherwise energy would be created. From this it follows that

$$M_{xy} = + M_{yx}.$$

Since self-induction, mutual induction, and capacity supply extra electromotive forces while the currents are changing, we can at once write down an expression for the current passing through any particular branch g

$$C_g = \Sigma \frac{E_x}{R_{xg}} - \Sigma \frac{L_x}{R_{xg}} \frac{d C_x}{d t} - \Sigma \Sigma M_{xy} \left\{ \frac{1}{R_{xg}} \frac{d C_y}{d t} + \frac{1}{R_{yg}} \frac{d C_x}{d t} \right\} + \Sigma \frac{z^2 K_z}{R_{zg}} \frac{d C_z}{d t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where we suppose each condenser K_z to be shunted by a wire of resistance z and no self-induction. Under these circumstances it has been shown in an earlier part of the paper that the extra electromotive force due to this cause is

$$+ z^2 K_z \frac{d C_z}{d t} = + z \frac{d K_z V_z}{d t} = z \frac{d Q_z}{d t},$$

where V_z is the potential difference and Q_z the charge of the condenser z.

If, with Maxwell, we define the electro-kinetic momentum of the branch x to be

$$P_x = L_x C_x + \Sigma M_{xy} C_y,$$

we may write equation (1)

$$C_g = \Sigma \frac{E_x}{R_{xg}} - \Sigma \frac{1}{R_{xg}} \frac{d P_x}{d t} + \Sigma \frac{z}{R_{zg}} \frac{d Q_z}{d t} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

In order to get the effect of a condenser whose terminals are merely connected to two points on the network, we shall have to consider the limit of $\frac{z}{R_{zg}}$ when z is made infinite.

We get, by integrating (2),

$$Q_g = Q_e - Q_p + Q_k \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where Q_g = total quantity which has passed through the galvanometer.

$$Q_e = \Sigma t \frac{E_x}{R_{xg}},$$

$$Q_p = \Sigma \frac{1}{R_{xg}} \{ (P_x)_t - (P_x)_o \},$$

$$Q_k = \Sigma \frac{z}{R_{zg}} \{ (Q_z)_t - (Q_z)_o \},$$

the suffixes t and o denoting the line of evaluation. If the currents proceed from one steady state to another, we can evaluate the effect of all condensers shunted by wires by diminishing the self-induction of each wire by Kz^2, K being the capacity of the condenser and z the resistance of the wire. In the case when z is infinite we must find the limit of $\frac{z}{R_{zg}}$.

Imagine the terminals of the condenser replaced by those of a battery, and let ρ be the ratio of the current through the galvanometer to that through the battery; then

$$\rho = \left[\frac{z}{R_{zg}} \right]_{z=\infty}$$

For imagine an electromotive force E to be located in the branch z. The ratio ρ is, by definition,

$$\frac{E}{R_{zg}} : \frac{E}{R_{zz}} = \frac{R_{zz}}{R_{zg}},$$

But $\frac{R_{zz}}{R_{zg}}$ is independent of z, as we show later (10); so that ρ is also

$$\left[\frac{R_{zz}}{R_{zg}} \right]_{z=\infty} = \left[\frac{z}{R_{zg}} \right]_{z=\infty}$$

because $R_{zz} = z + R_o$, where R_{oz} is the resistance of the network between the extremities of z, supposing z removed.

It follows $\frac{1}{\rho}$ = (coefficient of z in R_{zg}).

It is noteworthy that we may write equation (1)

$$C_g = \Sigma \frac{E_x}{R_{xg}} - \Sigma \frac{L'x}{R_{xg}} \frac{d C_x}{d t} + \Sigma \frac{z}{R_{zg}} \frac{d Q_z}{d t}, \quad (4)$$

where

$$L'x = L_x + \Sigma \frac{R_{xg}}{R_{yg}} M_{xy};$$

so that the total effect on the galvanometer will be exactly as if the self-induction of every branch x were increased from L_x to $L'x$, as above defined, and the mutual induction removed.

Equation (3) shows that for a complete cycle Q_p and Q_k will be each zero, provided the resistances of the bridge are not changed. If, however, as in an Ayrton and Perry's cycle, some of the resistances are changed, the cycle must be divided into parts during which no such change takes place, and the integrals for each part must be added. In such cases the self-induction of the galvanometer will probably produce an effect, and must be allowed for.

Thus Mr. H. B. Bourne, while experimenting at the Central Institution on the apparent resistance of a periodic make-and-break placed in one of the arms of the bridge, found that by adding self-induction to the galvanometer branch the result was considerably affected.

The definition given above of the positive direction of a branch serves our present purpose. It is, however, faulty in so far that a positive electromotive force in any branch does not necessarily produce positive currents in *all* the other branches. The ambiguity arises from the fact that the network functions R_{xy} are constrained by definition to be essentially positive quantities.

General Network of Conductors.

The most general case of a network of conductors is that in which p points are connected by branches in such a way that each point is the junction of three branches, and of three branches only. Any other network can be deduced from this by diminishing to zero the resistances of one or more of the branches. In the general case p must be even, since the number of branches is $\frac{3}{2} p$. Let $p = 2n$, and call n the degree of the network. If we increase to infinity the resistance of any branch, we merely diminish the degree of the network by unity.

There will be $3n$ branches, $3n$ currents, $\frac{3n(3n-1)}{2}$ network functions of the form R_{xy}, and $3n$ more of the form R_{xx}. There are only $(n+1)$ independent currents, since at each of the points of the network we have an equation of continuity, and $2n-1$ of these are independent.

Moreover, for each point of the network we have three equations of continuity for the network functions—

$$\left.\begin{aligned} \frac{1}{R_{xx}} &= \frac{1}{R_{xy}} + \frac{1}{R_{xz}} \\ \frac{1}{R_{yy}} &= \frac{1}{R_{yz}} + \frac{1}{R_{yx}} \\ \frac{1}{R_{zz}} &= \frac{1}{R_{zx}} + \frac{1}{R_{zy}} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where the branches x, y, z meet in a point. We shall get $(n+1)$ independent equations connecting the electromotive forces, the currents, and the resistances of the different branches. These equations will be linear for either currents or resistances. By solving for any current C_x we shall get

$$\Delta C_x = \Sigma E_y \Delta_{yx},$$

where Δ is a determinant of the resistances of degree $(n+1)$ which will be the same for each of the independent currents, and which, in consequence

Digitized by Google

of the simple sum and difference relation between these currents and the others, will be the same for all the currents. Δ_{yz} will be a first minor of Δ corresponding with the electromotive force E_y and the current x. Its degree is n. Suppose the only electromotive force is that in the branch y, then, from definition,

$$R_{xy} = \frac{\Delta}{\Delta_{yx}}.$$

Now Δ must consist of products formed by taking combinations of $(n+1)$ of the resistances. It can only consist of positive terms; for, from simple physical considerations, $R_{xx} = x + R_{ox}$, where R_{ox} is the resistance of the network between the extremities of the branch x, supposing x removed. R_{ox} must be positive, and is independent of x;

whence
$$R_{xx} = \frac{\Delta}{\text{coefficient of } x \text{ in } \Delta} = \frac{\Delta}{\Delta_{xx}} \quad . \quad . \quad . \quad . \quad . \quad (6).$$

The sign of Δ must therefore be the same as that of the coefficient of x. But x is any resistance of the network, therefore each term of Δ must have the same sign.

This argument also proves that Δ can contain no power of x higher than the first, for otherwise R_{ox} would involve x. Hence Δ consists of products of different combinations of $(n+1)$ resistances of the network, and consists of only positive terms. It does not involve all the combinations possible, because, although involving all the resistances, and although the same for each current, it has not been formed in a symmetrical fashion. It has been obtained by considering $(n+1)$ branches, no three of which meet in a point.

In the expression for Δ we must therefore exclude those combinations involving the product of the resistances of any three branches meeting in a point.

Δ consists of the sum of the products of the resistances of all combinations of $n+1$ branches which are such that independent currents may be supposed to exist in them . . . . . (7).

If we diminish to zero the resistance of any one branch of the network, Δ will be diminished by the sum of the products containing this resistance as a factor. We cannot introduce new products by this means.

Now let $a\ b\ c\ \ldots\ x$ be any $(n+1)$ branches of the network, and suppose we diminish the resistances of the remaining $(2n-1)$ branches till they are infinitely small. It will still be true that

$$R_{xx} = \frac{\Delta}{\text{coefficient of } x \text{ in } \Delta},$$

where x is any one of the $(n+1)$ branches chosen.

Now Δ will be infinitely small unless it contains as one of its terms the product $a\ b\ c\ \ldots\ x$, since any other product of $n+1$ resistances will contain at least one infinitely small resistance as a factor. If Δ does contain this product we shall have

$$R_{xx} = x + \text{terms infinitely small.}$$

Proceeding to the limit, we have

$$R_{xx} = x,$$

which means that the branch x has been short-circuited by making the $2n-1$ resistances zero.

Δ can therefore only consist of the sum of such products of $(n+1)$ resistances that the branches with which they correspond are each short-circuited by making the remaining $(2n-1)$ resistances zero. It must contain every such product, for if the remaining $(2n-1)$ resistances are zero we must have for each of the $(n+1)$ resistances

$$x = R_{xx} = \frac{\Delta}{\text{coefficient of } x \text{ in } \Delta},$$

which shows that Δ must reduce to and contain the product $a\ b\ c\ \ldots\ x$.

(To be continued.)

THE RELATION BETWEEN THE CROSS SECTION OF THE IRON IN ARMATURE AND FIELD OF THE GRAMME DYNAMO.*

By Mr. Dugald Jackson, of Cornell University.

The relation between the cross section of iron in the armature core to that in the magnet limbs in a dynamo machine is an important one. On its proper adjustment, in an otherwise well-designed machine, depends the attainment of maximum efficient output per pound of wire with minimum of iron. Of two machines designed for a given purpose, the one with a Siemens armature and the other with a Gramme ring, the path of the lines of force through the armature of the latter machine will usually be considerably longer than in that of the other. It is evident that special care should be exercised to make the Gramme armature of sufficient area of cross section that its magnetic resistance be not increased unduly. Siemens armatures from mechanical principles call for a goodly amount of iron, while an increase of cross section in a Gramme armature increases mechanical difficulties considerably. Consequently Gramme armatures usually have considerably smaller cross section than Siemens armatures in machines intended for a similar use, magnetic conductivity being sacrificed for mechanical convenience in the Gramme. How far this sacrifice may be carried without impairing the value of the machine must of necessity be specially determined for each individual case.

The question of how far the characteristic, and so the output of a machine, is influenced by variations in the cross section of the armature could be determined by Hopkinson's very beautiful method of predetermining characteristics. In a machine, the outline and dimensions of which are determined by conditions imposed, the curves of magnetisation, such as Dr. Hopkinson used, would be fixed for the field and air space. By plotting curves for armatures of various cross section, the area giving the best characteristic, and yet not unduly decreasing the internal diameter of the ring, would be evident. The value of the leakage ratio n might be estimated by Prof. George Forbes' method, if the shape of the diagrams were not too complicated.

An experimental solution of the problem for a little dynamo was made this term in the Physical Laboratory at Cornell University. If we had armatures for one dynamo made with cores of various cross-sections, the best section would be apparent from the characteristics. However, it is not necessary to wind the armatures, but simply to measure the number of lines of force passing through the armature for various magnetising forces—that is, observing the data for a curve of magnetisation. This may be done in several ways.

In the experiment referred to, a single turn of wire was placed around the section of the armature core perpendicular to the direction of the lines of force. This was connected with a ballistic galvanometer. The swing of the needle of the galvanometer was observed when the current was reversed in the magnetising coils on the field. The swing was thus proportional to 2 H A, A being the area of the turn of wire, and H the induction per unit area. Knowing the magnetising current and the corresponding swing for a number of points for each of several different armatures, the corresponding curve of magnetisation may be plotted. These curves are exactly similar to the total characteristic of a series dynamo or the internal characteristic of a shunt machine.

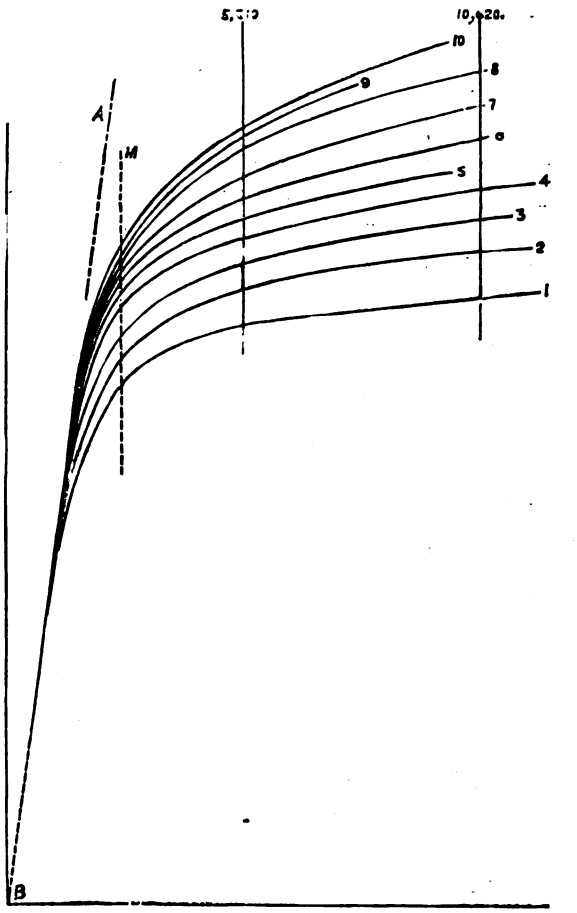

Fig. 1.

The field of the little dynamo experimented upon is of the single horse-shoe type standing upon the yoke. This is rectangular in cross section. The limbs are cylindrical and are held in place on the yoke with two pins each, the contact surfaces being perfectly plane. The yoke and limbs are of the best Norway iron. The pole-pieces are of a very good quality of cast iron, and are chambered to fit the upper ends of the limbs, which enter for a length of 7 cm., making the area of contact considerably greater than the cross section of the limbs. The cross section of the pole-pieces is much greater than that of the limbs. The bore of the pole-pieces is 10·8 cm. in diameter, there being a gap at the top and bottom subtending an angle at the centre of the bore of 51 degrees. The width of the surfaces on either side of the gap is ·3 cm. The corners of the pole-pieces are all rounded off.

Following are the dimensions:

Limbs (cylindrical)—

Length	20·3 cm.
Diameter	6·35 ,,
Area of cross section	31·66 sq. cm.
Distance apart from centre to centre	17·9 cm.

* Paper read before the American Institute of Electrical Engineers.

Digitized by Google

Yoke (rectangular)—

Length	26·8 cm.
Width	8 2 ,,
Depth	6·9 ,,
Area of cross section	56·6 sq. cm.

Pole-pieces—

Height	10·2 cm.
Width	10·2 ,,
Bore	10 8 ,,
Mean area of cross section	— sq. cm.

The magnetising coils consist of 785 turns on each limb, making a total of 1,570 turns.

The armatures were composed of thin punched discs of soft wrought iron obtained through the courtesy of T. Pray, jun., of Hartford, Conn. The discs were insulated by dipping them into shellac varnish and then built into armatures by placing them on wooden mandrels turned to fit their internal diameter. The variation in the cross section of the armatures was obtained chiefly by using armatures of the same number of discs, but of different internal diameters. As it was not possible to secure discs with the proper internal diameters to give all the area desired, some of the armatures were composed of fewer discs. In these, thin spaces were left between the discs, and the area enclosed by the exploring coil was slightly greater than that of the iron. The effect of this has been neglected as too small to be appreciable. The areas were obtained by multiplying the thickness of the discs, which was ·0462 cm., by the number on the armature.

The magnetising current was furnished by a number of storage cells. In the circuit of these were placed a tangent galvanometer and the magnetising coils. A reversing key was so placed in the circuit as to simultaneously reverse the current in the galvanometer and coils. The magnetic induction was measured by a ballistic galvanometer, as already explained. The observations were taken by Mr. F. R. Jones, an engineering student working in the laboratory. The regularity of the curves attests the care with which he carried out the work. I have here a sketch (Fig. 1) of the curves determined by Mr. Jones, which, I think you will agree with me, are very interesting.

The following table gives the areas of the cross section of the armatures and their ratios to the cross section of the magnet limbs :—

Armature No.	1	.....	17·75	Cm.	.....	Ratio	.....	0·561
,, ,,	2	.....	19 23	,,	.....	,,	.....	0·607
,, ,,	3	.....	20·70	,,	.....	,,	.....	0·654
,, ,,	4	.....	22·19	,,	.....	,,	.....	0·701
,, ,,	5	.....	23 66	,,	.....	,,	.....	0·747
,, ,,	6	.....	25·14	,,	.....	,,	.....	0 794
,, ,,	7	.....	27·36	,,	.....	,,	.....	0·864
,, ,,	8	.....	29·18	,,	.....	,,	.....	0·922
,, ,,	9	.....	34·49	,,	.....	,,	.....	1·09
,, ,,	10	.....	42·44	,,	.....	,,	.....	1·34

In curve No. 1, where the armature has little more than half the area of the limb, the turn in the characteristic is sharp, and the straight line representing the upper portion of the curve is almost horizontal. The rapid and great increase of magnetic resistance shown by the curve to the right of the line M must be due entirely to the saturisation of the armature. As the area of the armature increases, the turn in the corresponding characteristics grows into a longer sweep, and the upper part of the curve takes an increasing angle with the horizontal. Curves Nos. 9 and 10 are given by armatures greater in cross section than the limb, and though there is a difference in their areas equal to a quarter of the area of the limbs, there is very little difference in the total induction passing through the armature. The curve No. 10, then, probably very nearly represents the curve of magnetisation of the iron in the field and the air space. The straight line, which constitutes the lower part of the characteristic, being the backbone of the curve, as it were, must very nearly represent the line of magnetic resistance of the air space. By air space I mean the space between the pole-piece and armature.

Looking at the curves there, you see the armature No. 1 was highly saturated, or, in other words, had become of enormous magnetic resistance before the permeability of the field began to decrease appreciably. On the other hand, armature No. 9 has increased in magnetic resistance very little up to the point to which the characteristic has been carried, while the field is quite saturated. Between these extremes there are varying degrees of relative saturisation of the armature. In curve No. 7, the field and armature are apparently at about equal degrees of saturisation throughout. The curve (shown in Fig. 2) illustrates the effect on the total induction through the armature of the ratio of the area of the armature to that of the limbs. As ordinates are plotted total induction through the armatures taken from the characteristics on the section line M. The abscissæ are ratios of the cross-section of the armature to that of the limbs.

This curve is exaggerated in vertical scale so that its character may be more plainly seen. It shows obviously that the induction through the armature increased quite rapidly when the armature core was increased in area from ·5 of that of the magnet limbs to about ·75 of that of the limbs. From ·75 to ·9 there is still an increase of induction with increase of armature core, though not so good as before, and beyond ·9 the increase is of no practical importance.

If the section at M, Fig. 1, had been taken farther up the curves, the relative increase of total induction with increase in the area of the larger armature would not have been so marked.

The section at M is taken at 2,660 ampere turns ; that is, an absolute magnetising force of 33,420. The absolute total inductions for this magneto-motive force are shown in the curve, Fig. 2. These were determined by comparing the throw of the ballistic galvanometer given by the armature with that given by a standard coil turned through 180 degrees in the horizontal component of the earth's field. The value of the horizontal component at the place of the standard coil was determined by comparison with that in our magnetic observatory by the use of the compensated magnetometer.

We may safely assume that the cross section of the armature should be about ·75 of the cross section of the limbs if the wire on the armature is to have the greatest activity without an excessive quantity of iron in the core. By making the cross section of the armature ·6 of that of the limbs, a loss of 10 per cent. of the total induction, when the ratio is ·75, would be made, and consequently an equal loss in E.M.F. and the output of the machine. This is a case where the permeability of the field-magnet is equal, or very nearly equal, to that of the armature. If the permeability of the armature core were greater than that of the field the area of armature could be a smaller ratio.

No allowance has been made in this for the effect of a current in the armature. That should at any rate be small, except in the case of arc lighting machines, where a great number of turns of wire are placed on the armature with the purpose of gaining stability in the lights.

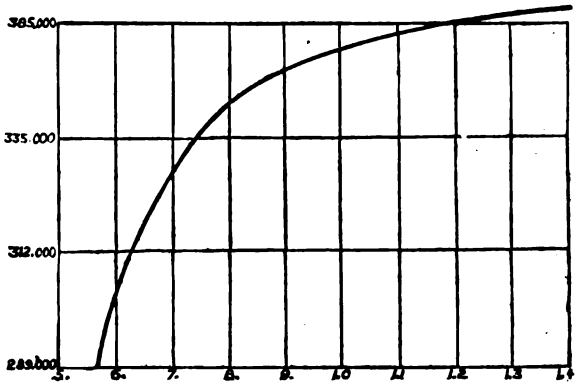

FIG. 2.

The absolute intensity of the magnetic flow per square cm. in the armature was quite high. In armature No. 5, the section of which is practically ·75 that of the limbs, an induction of 14,000 per square cm. was given by 2,666 ampere turns. For about 10,000 ampere turns the induction was 17,000 per square cm. 10,000 ampere turns gave an induction of 11,000 per square cm. through armature No. 10, and about 18,000 in armature No. 1. The latter was increased to nearly 19,000 by 12,500 ampere turns.

The induction per square cm. corresponding to the best conditions in this machine is 14,000 per square cm. This is high for a dynamo. I believe Dr. Hopkinson has placed the figure in the Edison-Hopkinson machine as 8,000, and, if true, this is probably seldom exceeded. I am aware that the value apparently reached 20,000 in the Manchester dynamo in Hopkinson's late tests, but that high value cannot be given much weight, even though the armature was pretty well saturated. I may be placing the limit entirely too low, as I have a number of records where from 10,000 to 15,000 is claimed, but simple claims are endowed with great uncertainty.

It may be interesting to note the ratio of the areas in two or three dynamos of ordinary size. It is impossible to estimate the area of iron in an armature with wire on it, because of the uncertainty in the space occupied by insulating material between the iron discs. In the record of their late tests the Hopkinsons have given the areas of the armature and magnet limbs in the Edison-Hopkinson and the Manchester dynamos. In the Edison-Hopkinson machine the field had probably nearly the same permeability as that of the armature core. The cross section of the armature was about ·8 that of the field, and the field was considerably more saturated than the armature. In the Manchester dynamo the field probably had a lower permeability than the armature, and they were about equally saturated. The cross-section of the Gramme ring in this machine was about ·6 that of the cross-section of the field.

COMPANIES' MEETINGS.

United Telephone Company (Limited).

The seventh annual ordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on the 5th inst., under the presidency of Mr. James Brand.

The SECRETARY (Mr. Thomas Blaikie) read the notice convening the meeting.

The CHAIRMAN then said : Gentlemen, I will commence the few remarks I have to make with one or two references to the accounts. You have all had a report, and I trust you will consider it sufficiently clear to speak for itself; but there are one or two points I will allude to. The capital expenditure this year has been £41,500; of this sum £36,000 has been

Digitized by Google

used for the development of the metropolitan system, and £5,000 has been spent for telephones in use in our subsidiary companies distributed all over the country. Then, as to our revenue and expenditure, our metropolitan system, which, as you are aware, is now entirely separated from the rest of our business, shows an income of close on £90,000, being an increase of about £8,000 over the previous year. This is a substantial figure, but would have been disappointing to us did we not know that our progress had been retarded by the snowstorm in December last. To earn this increase we have spent about £2,000 less in working expenses. In addition to our expenditure for working expenses, we have spent £11,000 in repairs and replacements and by the damage through the snowstorm, and have put about £5,000 to suspense account for liabilities which are possible to turn up. Our reserve fund is now over £102,000 by the addition of over £4,000 from exceptional sources, and £1,200 has been set aside for depreciation of instruments in use all over the country. As to the dividend, the amount available for the whole year is £62,236. Of this you have received an interim dividend at the rate of 10 per cent., and we now propose to make this up to 13 per cent. for the year by a further payment of £35,804, and to carry forward to next year £4,053. The comparative statement we have placed at the end of the accounts will enable you to compare easily each year since the formation of the Company. You will notice that our metropolitan system is now debited with £11,000 for royalties, the same as if it had been worked as one of the subsidiary companies. It is now, however, divided into ten separate sections, each section having an efficient staff to develop, canvass, and work it. This division has for the moment caused some extra expenditure, as we have hired extra stores, &c., in most of the districts, so that all materials may be at hand for whatever work there is to do. But our extra expenditure will be more than repaid by greater efficiency. By this time next year we shall have 14 divisions, and the carrying out of the work for forming these divisions and working is even more difficult and intricate than the opening up of telephonic systems in the same number of separate towns. Then, as to switch-boards and the general working of the system; when I last had the pleasure of speaking to you I told you that we were completing the renewal of our two largest exchanges and one central trunk exchange with the most perfect switch-boards in existence, and that shortly we hoped to show our subscribers a much improved working. Well, in October last we had got our exchanges into a high state of efficiency, and our calls at the end of December had reached the high figure of 42,000 in one day, or equal to 84,000 telegrams. We were congratulating ourselves, and beginning to feel that our subscribers were well pleased, when the great snowstorm took place—you will recollect it was on Boxing Night—and in a few hours upset the labour of the whole year. This snowstorm hit us in two ways. It not only upset our system, which was working so well, but prevented us for nearly four months canvassing for new subscribers, and stopped all our plans for further development which we were preparing to carry out during the spring months; and it was necessary to devote the whole of our energy to putting our old subscribers once more in connection, rather than try to get fresh customers, which we knew could not be joined up. A good deal of annoyance was expressed and vexation caused by the apparent long delay that occurred in the replacement of our system. Many people thought that our work could have been done quicker, and ought to have been done quicker. But I can assure you that we did everything that seemed possible to us, and used every good man that was available at the time. You must remember that we did not stand alone in our misfortune. The storm was general all over the country, and every great railway as well as our subsidiary companies were suffering, and it was impossible to get trustworthy and skilled men at a moment's notice to fulfil the great demand for this special labour that had arisen. We did our best to overcome our troubles, and I believe we have succeeded fairly well. Our calls have again reached the position they were in when the disaster occurred. While we suffered much from this snowstorm, I trust we have gained somewhat by the lessons we have learned. We have secured the services of a very efficient consulting engineer, Mr. John Tomlinson, who has superintended the replacement of our wires, poles, and derricks. We hope we have found out our weak points, and have mended them in such a way that we are advised will minimise the effects of any future trouble. We should be glad, of course, if we could so arrange our wires as to avoid any further mishap; but the state of the law forces us to do work in one way that we would often like to do in another. If the recommendation of the Committee of the House of Commons of 1885 could be carried out to even a modified extent, we could overcome many of our difficulties without the least prejudice to the public, and certainly all danger from a breakdown of our wires would be done away with if we were allowed to run them in a straight line along the streets at right angles. This would avoid all the necessity of long spans, which is our principal weak point. I am glad to tell you that no accident whatever occurred to the public during all the time of the snowstorm. I may tell you that the telephone enterprise of Great Britain now comprises 212 exchanges, 19,000 subscribers and 225,000 messages per day average, with a gross income of £325,000 and about 30,000 miles of wire. Very little money has been spent by us in law, and there has been no litigation of any consequence in regard to the patents, since the decision of the Court of Appeal in favour of the Company in the action against Messrs. Bassano and Slater, of Derby, about twelve months ago. There was talk of an appeal in that case by the defendants to the House of Lords, but the time for notice has expired and no notice of appeal has been given. As might have been expected, a good deal of ingenuity has been exercised in attempts to construct good working telephones which do not come within the scope of the Company's patents, and if the paragraphs which appear from time to time in the newspapers are to be believed, these gentlemen are doing great things. But, singularly enough, they seem never to get beyond newspaper paragraphs. As soon as they make a decent instrument they seem to come within the Company's patents, and when they keep outside them they make instruments of no real commercial utility. We will not fail to maintain in the future, as in the past, the valuable patent rights secured by so much labour and expense, but we think we are best protecting our property by allowing many of these ingenious efforts to fail by their own weakness rather than by bringing the formidable and expensive artillery of the law to bear upon them in every case. That, gentlemen, I think is all I have got to say to you. I shall, however, be glad to answer any questions, or hear any suggestion that any shareholder has to offer before I put the resolution that the report and accounts be adopted.

The DEPUTY-CHAIRMAN (Mr. J. Staats Forbes), in seconding the motion, called special attention to the fact that the large sum of £15,777 had been charged boldly against the revenue of the year to meet the costs of the damage sustained by the Company through the severe snowstorm last December. That exceptional expenditure might fairly have been spread over a period, but it had been at once dealt with, and still they were able to pay the same dividend. He could not refrain from referring to the services which the Chairman, at great personal risk, rendered the day following the disaster; and the Managing Director, and, indeed, the staff generally, also deserved the warm thanks of the shareholders.

Mr. S. J. BUTCHER asked whether the Directors had considered the policy of having underground wires for, at least, the trunk lines. He thought that with underground lines they would be less liable to interruptions, the fear of which deterred new subscribers from joining.

Mr. WILLIAM ABBOTT said he was quite ready to admit that the Directors had had a very bad time during the snowstorm, but he must also not shut out from his mind that they were likely to have snowstorms again. He was greatly pleased to hear that they had called to their aid an efficient engineer. He thought that the Directors ought to have found out before the weak places in the system, but now that they were beginning to do so he had no doubt that they would discover a remedy. He must call into question one of the Chairman's statements—that the working of the telephone was giving perfect satisfaction at the time of the snowstorm. As one of the earliest subscribers he could say that that certainly was not the case. A large number of shareholders present were subscribers, and they had had a great deal to complain of with respect to the working of the Company's system. He certainly had no desire to throw cold water on the undertaking. On the contrary, he believed they were in possession of a veritable gold mine, second only to the telegraph itself; but he wanted the Directors to understand that what the shareholders expected was that the Board would leave nothing undone in order to secure rapid progress being made in the lifetime of the present subscribers. The Chairman had spoken of the comparative statement given at the foot of the accounts. Well, he (Mr. Abbott) observed from that that they had made the smallest amount of progress last year in the gross receipts than in any year since the Company was established. They could blame the snowstorm for a great deal of loss of net revenue, but they could not blame the snowstorm for the great loss of progress in the gross revenue. The gross revenue from the metropolitan system was £95,655 in 1886, and for the present year it had been only £100,899. What did that mean? Was it because they had not made any special effort to increase the number of the subscribers so long as this system was in a state of disorganisation? If so, that was an answer to his criticism. There was a feeling out of doors that there was a want of vigour shown in the administration of the Company's affairs. One of the things said to support that was that nothing had been done by the Company to extend its usefulness outside of London. He knew that on the Continent they had established a trunk line between Paris and Brussels, and he believed that that was doing remarkably well. Why should they in that Company not do something of the same kind? Was there any bar to their making a connection between the subscribers in London and Manchester and Liverpool? If so he wished the Chairman to let the shareholders know it; but, interested as the Company so largely was in the subsidiary companies, the sooner that the subscribers in London and the country had full advantage of conversation through the telephone the better for both of them. Last July he made a very daring proposal to the Chairman, to the effect that some effort should be made to separate the shares of the subsidiary companies held by them, and that they should be placed in a trust and distributed among the shareholders, the control of those companies being still vested in the Board. The Chairman told him on that occasion that they would think over the matter, and he (Mr. Abbott) would like to know to what extent their thoughts on the subject had carried them. Was there anything objectionable in his suggestion, or did they see their way to carrying it out? If not in the shape he had suggested, perhaps the financial genius on the Board, which he was pleased to acknowledge, could propound some other scheme, by which the shareholders might receive in the form of a bonus the very large amount of dormant capital held by them in other companies, and from which the Company derived a certain amount of revenue. He thought they were all agreed that they had a great and valuable property.

Mr. HENRIQUES said that a most important matter in the report was the reference to the snowstorm, and having such an efficient Board he thought they would do well to turn their serious attention to the strengthening of the supports which carried the wires. He had been in New York and had seen much more serious snowstorms than anything that was seen in this country, but he had not seen anything of the fall of wires such as had been the case here. He was an engineer, and knew something about what he said; and he said that anyone with ordinary knowledge would not have put up such weak supports to carry such wires as theirs and of such great weight. With a small expenditure the supports could have been strengthened, and thus, in his opinion, much of the loss they had sustained could have been avoided. He desired to know why, in the general revenue account, it cost nearly £8,000 to collect a sum of £43,000, which was the net revenue. He supposed that they took away from that the depreciation of instruments, but even then it was an enormous percentage to

Digitized by Google

charge the accounts with in order to secure £43,000 out of £51,000. Coming on to the Metropolitan District account, it seemed to him that the Directors received the lion's share of the whole business. The salaries and wages amounted to £5,986, while the salaries of the Directors came to £5,298—in other words they got as much as the crowds of workmen who must necessarily be employed to do all the work. He considered that the enormous profits earned by the Company ought to go in a larger proportion to the shareholders.

Dr. BROWN said he had been greatly struck with the long lengths of wire crossing the streets, and they were dangerous owing to the want of solidity in the houses on which the supports stood. Every care ought to be used to fasten them so that snowstorms should not affect them.

Sir J. GOLDSMID, M.P., said he was chairman of a company which had a capital of £4,000,000, and the Directors were paid £5,000 a year. That was a very large business, and involved enormous attention on the part of the Directors. He saw that in the case of this Company the capital was £500,000, and the Directors had received £5,300 for the year. He knew that the system of paying directors by commission was the French system, and that it was adopted in many companies; but it was a bad system, and he regretted to see it introduced in London companies. He held that it was the duty of the Directors to reconsider the Articles of Association, and fix a large and liberal salary for themselves, not exceeding a fair amount, which ought to be paid to them for their services. By the present arrangement if the business increased as it ought to the Directors would receive a great deal more than they did already. He had heard the opinion expressed freely that the Directors had not done enough to extend the benefits of the system to the suburbs. He desired to state that his remarks had been made in no spirit of hostility to the Board.

The CHAIRMAN said he would inform the shareholders of how the present system of remunerating the Directors began. He did not think that the amount of capital of a company was anything to do with the question of the remuneration which the Directors should receive. When their Company began it had no capital at all, and it had been made by the efforts of himself and a few others who had been very devoted to the thing. It was much more difficult to manage at the outset when it had no capital than it was now. He wished to state for himself that he had not been paid half as much by the Company as he could have earned at any other business, and the amount he now received from the Company was not large, considering the work he had done, and which he had to do every day. Had Sir Julian Goldsmid spoken to him on the subject before the meeting he believed he could have shown that gentlemen that the Directors were not paid more than they deserved. He did not think it was a bad system to pay directors by commission. He had devoted himself for three years before the thing was got in order, and he received not a shilling all that time for what he did. Then he staked a good deal of money in the concern, and now that it was beginning to do well the Directors were getting a fair proportion; but he did not think that £5,000 was a very large sum for them to receive out of the profits considering the peculiar nature of the work. With regard to the extension of the benefits of the telephone to the suburbs, he knew it was a difficult matter to give satisfaction, but there were great obstacles in connection with extension to the suburbs. When by persistence they had forced lines out to different places they could not get the subscribers. He had got a line established at Tooting, with a call room there and at Clapham, but they were waiting for way-leaves—a question which was even more difficult in the suburbs than in London. The more they looked into these matters the more he was sure they would agree in believing that the Directors had done their best. Dr. Brown had referred to the length of the wires across the streets. That was so, but they could not help themselves in the matter.

Dr. BROWN: We want the Government to help us.

The CHAIRMAN, continuing, said that there was a recommendation by a committee of the House of Commons in 1885, but there had been so many great questions before Parliament and the Government that the telephone had been rather neglected of late, and it was not well for the Company to be always stirring in the matter. Mr. Henriques had spoken of the damage done by the snowstorm, but there had not been so many supports that had broken down. They were not allowed always to go on the best of roofs, and they could not re-roof old and rotten houses. They were obliged to put their poles where they could get the way-leaves. A great many of the way-leaves were on public houses, a great many of which in outlying places were roofed with tiles. Then Mr. Henriques had said that the supports were weak because they were overloaded; but they were overloaded because they could not get more roofs to put their supports on. They were daily doing all they could in regard to these matters, but they could not go where they liked, and they could not have as many poles as they liked, for which reason they were very often obliged to put on more wires than they would otherwise like to do. They did not pay £8,000 to collect the revenue. There were a variety of things included in the amount mentioned. There was the enormous work of the establishments, advertising, rent (which alone was £1,600), depreciation of instruments, &c. Then, Mr. Henriques said that the workmen ought to receive more.

Mr. HENRIQUES: No, I said that the Directors ought to receive less.

The CHAIRMAN: Ah, well I think you are wrong there [laughter]. Speaking for myself, I am sure you are wrong.

Sir J. GOLDSMID said he did not think that what he had said had been properly understood. What he had said was that the remuneration of the Directors, which he considered high now, would, by the Articles of Association, go on increasing with the increase in the revenue of the Company, and he had suggested that the Articles of Association should be reconsidered, with a view to putting the Directors' remuneration on a fair footing.

The CHAIRMAN said the Directors would be most happy to consider the suggestion. Mr. Abbott had spoken about the shares in the subsidiary companies, and he had told that gentleman on a former occasion that if he could show them a plan which would make the shares of the Company more valuable in the market without taking away from their intrinsic value, they would be very glad to consider it. It might be very nice to divide the shares in the subsidiary companies, but if they did that there would be less value in their shares of the United Company, and they would lose the power they now possessed in the subsidiary companies by virtue of the number of shares held. Mr. Abbott had spoken about telephonic communication having been established between Brussels and Paris but he did not know whether they had in those cities as many difficulties to contend against as they had in London. The Directors had made all kinds of experiments, in connection with which they spent a great deal of money, and no doubt they would succeed ultimately. At present, however, he would be wrong if he told them that under existing circumstances, or circumstances that were likely to arise at present, they could get commercial telephonic intercourse between London and Manchester. He believed that if they could get a free line—free from telegraph wires and other matters of induction—they could get communication. They were doing what they could in the matter, and he hoped they would be able to give the shareholders a better account before their next meeting. They expected to be at Tilbury in two months, but it took a long time to put up these wires. Although it had been said that great satisfaction was not being given by the working of the system before the snowstorm, the Directors thought that the service had been greatly improved at the end of last year by the new switch-board, and he thought that that fact was evidenced by the statement he had made, that the calls had increased at that time to 42,000 a day. He was sorry that any dissatisfaction should have been expressed, but that would not prevent them from trying to improve matters. For four months after the storm they were making their old system good, and they could not very well develop new work while the old work was still undone. The patents would last four and a-half years from now. He thought that the danger of overhead wires looked greater than it was. They had never had an accident yet. He was not quite sure that they would obtain great efficiency by placing their wires underground, for even in the case of the telegraph a great deal of efficiency is missed.

A SHAREHOLDER inquired what the object of the reserve fund was, seeing that it was not applied to any great catastrophe such as occurred to them last winter.

The CHAIRMAN said that a great deal of the reserve fund was in the working of the Company—a fact which rendered it unnecessary for them to call up money and issue shares. The shareholders derived the benefit of the reserve fund in that way.

A SHAREHOLDER wished to know in what way the Directors would consider the suggestion of Sir Julian Goldsmid as to the question of their remuneration.

The CHAIRMAN said he could not state in what way they would consider the suggestion, which had only just been made.

A SHAREHOLDER: Supposing we could pay 20 per cent. next year?

The CHAIRMAN: Well, what a good thing for all of us!

Mr. E. DWYER GRAY, M.P., said he desired, as he was not present at the last meeting, when the shareholders did him the honour to elect him, to thank them for the confidence they had shown in him. There was always a certain delicacy in members of a Board defending their own salaries, but as the junior member of the Board, and as one who had had nothing to do with the hard work and tremendous exertions through which Mr. Brand and Mr. Forbes, and other members of the Board had gone, when the Company was in its infancy, and when most people regarded the telephone as a toy, he could approach the matter from an impartial standpoint. The effect of Sir Julian Goldsmid's proposal was this—that the gentlemen mentioned having made the Company a success should not be permitted to participate in its success on the lines to which the shareholders readily agreed before the success was accomplished. All the shareholders subscribed to the Company on the basis of the Articles of Association and the Memorandum of Association, which provided a certain method of remunerating the Board. Now, however, it was in effect suggested that they should turn round and say that the Directors had made the Company too successful, and that they ought not to be remunerated as they were entitled to by the original agreement. One gentleman had intimated that it would be a disastrous thing if a dividend of 20 per cent. could be paid next year, as in that case the Directors would receive so much more; but what would be the value of the shares and the position of the shareholders if 20 per cent. could be paid? He thought that they ought rather to pray that the Company might be able to pay 20 per cent than that they should look forward with any feeling of dismay to such a dividend. He contended, whether it was a general principle or not, that it was a sound commercial principle to pay directors by results. He was a member of the Committee of the House of Commons which investigated the question of overhead and underground wires. One shareholder had suggested that they ought to consider the propriety of trying to adopt the underground system. The evidence before that Committee, however, was clear—that the underground system was not as satisfactory for telephonic purposes as having the wires overhead, and that it was far more expensive. If the shareholders were serious in their desire that an effort should be made generally to adopt the underground system there would be no necessity to consider Sir Julian Goldsmid's suggestion, because the Company would have to provide £1,000,000 more capital, and reduce the dividend to 5 per cent., when the Directors would not be overpaid. That was what the result would be of adopting the underground system, which they might be driven to adopt, but which it would be very unwise for them to seek to establish in the teeth of the recommendations of the House of Commons Committee, who recommended that the Company should have increased facilities in regard to overhead wires. As to the lesser rate of progress in their gross revenue to which Mr. Abbott had referred, the new business had naturally ceased while the old business was dislocated; but new subscribers were coming

Digitized by Google

in again, and they hoped next year to show a better state of things. The reduction of the net profit and the reduction of the rate of increase in the gross revenue were clearly traceable to the same cause—the severe snowstorm of last December. Though there might be snowstorms every year, the evidence before the Committee to which he had referred showed that such disastrous snowstorms as that of last December occurred in the metropolis about once in every ten years. As to what Mr. Henriques had said about severer snowstorms in New York, he would point out that there was a very great difference between one snowstorm and another. One storm might cover the ground feet deep and do no harm to telephone wires, and another stowstorm, where there was scarcely any snowfall, might do immense injury. In New York the atmosphere was dry, and snow fell in small particles, and did not accumulate on the wires, to which no harm was done; but when it fell almost in a melting condition, was then succeeded by a frost, followed by a thaw and another snowstorm, great injury was done to the wires. The question of extending telephonic communication to other towns was beset by great difficulty on account of the attitude of the Post Office towards the Company, and the difficulty of obtaining way-leaves. In view of the difficulties that had to be encountered it was a matter of astonishment to him that the telephone had made such progress in this country as it had.

Mr. BENSTEAD said if he could get a dividend of 25 per cent. he would be quite satisfied to give the Directors the extra remuneration that such a dividend would entitle them to. It had been rumoured that there would be a very great difference in their profits in the current year, owing to the abatement of the yearly fees paid by subscribers through their not having the full use of the telephone during the time the system was being put in repair after the great snowstorm last December.

The CHAIRMAN said that that had all been provided for, and they had put aside more money than they believed would be requisite to meet any contingency.

The motion was then adopted.

Mr. JAMES BRAND and Mr. J. S. FORBES were then re-elected to their seats at the Board.

On the motion for the reappointment of Mr. Joseph B. Morgan considerable discussion followed relative to the amount of fees paid to that gentleman, the value of whose services was generally recognised, and as to the possibility of the Company engaging the whole of his time, at an additional remuneration if necessary. It was pointed out that it was advantageous in the interests of the Company that Mr. Morgan should occasionally be out of London in connection with his position on the Boards of the subsidiary companies, as representing the Company. It was also stated by the Chairman that while they would be only too glad to have the whole of Mr. Morgan's services, that was not so necessary since the appointment of Mr. Tomlinson. Eventually Mr. Morgan was unanimously re-elected.

The retiring auditors, Messrs. Quilter, Welton and Co., and Messrs. Price, Waterhouse and Co. were re-elected.

On the motion of Mr. Abbott, a vote of thanks to the Chairman and Directors was passed, and the meeting then separated.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 1st inst. amounted to £3,361.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return of this company, made up to the 15th of June, was filed on the 22nd ult. The nominal capital is £100,500, divided into 20,000 shares of £5 each, and 500 shares of £1 each. Only 150 of the £5 shares have been taken up; and the full amount has been called and paid thereon.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of June was 3,615, estimated to produce £2,750, against 3,377 messages, producing £2,767, in the corresponding month of last year. The traffic receipts for the month of March, estimated at £3,650, realised £3,727.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for June amounted to £1,563, against £1,522 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—The Eastern Telegraph Company give notice that the time for the exchange of the company's Four per Cent. Mortgage Debenture Stock, in place of the Five per Cent. Debentures, due 1st August, has been extended to July 16th.——The company announces that, subject to final audit, the accounts show, after placing £48,000 to reserve fund, a balance available for dividend sufficient to pay at the general meeting on 14th inst. the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, and a final dividend of 2s. 6d. per share, with a bonus of 1s. per share free of income tax on the ordinary shares, making with previous payments on account a total dividend of 5½ per cent. on those shares for the year ended 31st March, 1887.——The traffic receipts of this company for June, 1887, amounted to £45,426, and to £45,100 in the corresponding period of 1886.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June, 1887, amounted to £35,138, and to £38,894 in the corresponding period of 1886.

GREAT NORTHERN TELEGRAPH COMPANY.—The latest traffic returns of this company are as follows:—Receipts in June, 1887, £23,600; from 1st January to 30th June, 1887, £127,120; corresponding months of 1886, £124,560; ditto, 1885, £142,340.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ended 30th June were £4,400.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 1st inst. were £2,540, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 30th June are £2,921, as compared with £2,881 in the corresponding period of 1886. The February receipts, estimated at £5,844, realised £5,852.

THE SIMPLEX ELECTRICAL SYNDICATE

(LIMITED),

Of No. 109, Farringdon-road, London,

Are prepared to NEGOTIATE for the SALE of their ARC LAMP PATENT in the following countries:—The United Kingdom; Austria; Belgium; France; New South Wales; Victoria; South Australia, and New Zealand.

For Simplicity of Construction, Steadiness in Burning, and Brilliancy of Light, this Arc Lamp is unsurpassed.

SIMPLEX ARC LAMPS

can be made of all sizes as single Carbon Lamps, from 100 C.-P. upwards, and can be used in parallel circuit with Incandescent Lamps. Any continuous current Dynamo will suit them.

THE SIMPLEX ARC LAMP

(Single and Double) will run both in series and parallel circuits. Two series single Carbon Lamps can run in parallel with Incandescents on an Edison 110-volt machine.

THE FOLLOWING LAMPS HAVE BEEN MADE, AND HAVE BURNT SUCCESSFULLY:—

Small Parallel,					taking	**50**	volts,	**6-8**	**amperes.**
„ Series					„	**50**	„	**10**	„
Single Parallel, 8 hours,			**2,000 C.-P.**		„	**50**	„	**10**	„
Double „	**16**	„	„	„	„	**56**	„	**12-15**	„
Single Series,	**8**	„	„	„	„	**45**	„	**10**	„
Double „	**16**	„	**3,000**	„	„	**60**	„	**15**	„

THE SIMPLEX ARC LAMP

Can be seen burning at No. 6 Platform and at the Bookstall of Liverpool-street Station, Great Eastern Railway; also at the Hotel Windsor, Victoria-street, Westminster; also at the Dudley Exhibition, and at Leeds.

For further information apply to the Secretary, as above.

June, 1887.

Digitized by Google

NOTES.

WESTON-SUPER-MARE.—The Taunton Electric Light Company are about to place some arc lamps in the streets of this town.

AYRTON'S "PRACTICAL ELECTRICITY."—We learn that Prof. Ayrton's "Practical Electricity" is now being translated into the German and Spanish languages.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The meeting of the French Association for the Advancement of Science will be held at Toulouse, from September 22nd to 29th next.

THE ELECTRIC LIGHT IN OMNIBUSES.—One of the vehicles of the London Road Car Company running between Liverpool-street and Victoria Station has been supplied with an "Eclipse" primary battery, which is used for lighting an incandescent lamp.

TELEGRAPH EXTENSION IN ZUCATAN (MEXICO). — The extension of the federal telegraph system in Zucatan is to be undertaken at once on a large scale, and it is expected that all the important points in the State will be connected before the end of the present year.

THE BRAY ELECTRIC TRAMWAY.—The application for an Order in Council to authorise the construction of the proposed electric tramway between the Dublin, Wicklow, and Wexford Railway Station at Bray and the entrance to Bray Head will be heard at Dublin Castle on Wednesday next.

ELECTRIC COMMUNICATION WITH LIGHTSHIPS.—The committee appointed to consider the subject of electrical communication between lightships and the shore will report in favour of an eighteen months' trial of the system adopted in connection with the Sunk lightship off Harwich. This cable was fitted by the Telegraph Construction and Maintenance Company.

ELECTRIC LIGHTING IN SOUTH LONDON.—At the last meeting of the Vestry of St. George's, Southwark, a letter was read from the agents for the South Metropolitan Electric Supply Company intimating the intention of the company to apply for provisional orders to enable them to supply electricity for lighting and other purposes in several streets and places in the district.

THE INFANTA OF SPAIN AND ELECTRICITY AS A MOTIVE POWER.—Our Spanish contemporary *La Electricidad* states that the Science and Art Academy of Cadiz has announced a scientific, artistic, and literary competition, and amongst the prizes are bronze and marble vases, offered by the Infanta Doña Isabel, for the best treatise upon "Electricity as a Propelling Power in Navigation."

THE PARIS-ROUEN TELEPHONE LINE.—According to a French contemporary, the telephone line between Paris and Rouen, which was opened for the public service on the 25th June, is working very badly; conversation is said to be most difficult, and at times impossible. This is the result of false economy in the construction of the line, for which galvanised iron wire was employed.

THE LANCASHIRE AND YORKSHIRE RAILWAY COMPANY AND THE POST OFFICE.—Owing to a dispute between the Postmaster-General and the Lancashire and Yorkshire Railway Company, at the end of June last the whole of the telegraph offices at the stations of this company were closed for the public service. The dispute has, however, since been adjusted, and the offices have been reopened.

THE TELEPHONE IN FRANCE.—The following statement shows the extent of the work carried out in France by the Société Générale des Téléphones:—The number of subscribers to the Paris Exchange is 5,010, an increase of 464 during the last six months. There are ten exchanges in the provinces, with a total of 2,283 subscribers, thus distributed—Lyons 720; Marseilles 403; Bordeaux 399; Le Havre 217; Rouen 115; St. Etienne 107; Nantes 105; Calais 95; Alger 80; Oran 42.

TEMPORARY ELECTRIC LIGHTING.—At the ball recently held at the Inner Temple, the marquees, supper rooms, &c., were lit throughout with the electric light, a total of 220 lights of 16 candle-power being supplied from a portable Marshall engine and an Elwell-Parker dynamo placed in Mitre-court. In addition to the above, there were over 120 lights supplied from the permanent plant, which has recently been extended. The work was carried out by Messrs. Drake and Gorham, of 2, Princes' Mansions, Victoria-street, S.W.

RAILWAY CARRIAGE ELECTRIC LIGHTING IN INDIA.—The *Indian Engineer* says that experiments are shortly to be made with a view to the introduction of the electric light into railway carriages in India. Owing to the large distances to be traversed in India night journeys are a necessity; in fact, by reason of the comparative coolness of night travelling, many people prefer trains which run after dark. The carriages are now lighted by the old-fashioned oil lamps, which give only a dim light, and often no light at all when the railway servants omit to trim them.

TRANSFORMERS IN AMERICA.—The Westinghouse Electric Company is meeting with an enormous demand for the alternating system for central station work. The shops employ about 1,200 men and are working a night gang. The lamp factory is already the largest in the United States. There are now over forty stations under construction or in operation. Recent contracts have been made in Pittsfield and Springfield, Mass.; Hartford, Conn.; Denver, Colorado Springs, and Ouray, Col.; St. Louis, Mo.; Cornwall, Canada; Littleton, N. H.; Portland, Me.; Morristown, N. J.; Staten Island, N. Y.; Galveston, Tex., and Charleston, W. Va.

NEWCASTLE EXHIBITION.—The Prince of Wales and his sons visited this exhibition on Wednesday last, and took a ride upon the electric tramway, Mr. Manville having the honour of driving the car upon the occasion. We believe it was also in contemplation to initiate the royal visitors into the mysteries of electric welding, but whether time did not permit, or whether the royal interest was not sufficiently aroused, it at anyrate appears that the Prince did not avail himself of the opportunity of witnessing this most recent and most interesting application of electricity. We may add that we shall shortly give a special description of the electrical specialities of this exhibition, in which will be found some interesting details not hitherto published.

MAGNETISM AND SOLAR PHENOMENA.—Recent observations at the observatory of Lyons have led to some interesting results in connection with the perturbations of terrestrial magnetism. Curves plotted from these observations show that each period of maximum perturbation coincides with the passage of a group of solar spots or a group of faculæ at its shortest distance from the centre of the solar disc. There does not seem to be a relation between the intensity of the perturbation and the diameter of the spots. The conclusion come to by M. Marchand from a consideration of the results is that there is a direct relation between the perturbations of terrestrial magnetism and the displacement in regard to us of certain solar elements accompanying the spots and faculæ.

THE JUBILEE OF THE TELEGRAPH.—A meeting of the members of the general committee appointed to make arrange-

Digitized by Google

ments for the forthcoming dinner at the Holborn Restaurant to commemorate the fiftieth anniversary of the construction of the first telegraph in this country was held on Tuesday at the offices of the Society of Telegraph-Engineers, The Sanctuary, Westminster. Mr. W. H. Preece, F.R.S., occupied the chair. A number of details as to the preparations for the festival were submitted by the sub-committee, and discussed, and among other things it was announced that up to date the number of applications for tickets had been about 200, while the guarantee fund amounted to upwards of £250. A meeting is to be held next Tuesday, by which time the committee will be in a position to state their final arrangements.

SHIP LIGHTING.—A very successful electric light installation has just been completed on the ss. "Zaraté," the latest addition to Messrs. Houlder Brothers' line of London and River Plate steamships. The plant consists of a Phœnix compound-wound dynamo, driven with an ordinary leather belt by one of Shanks's Caledonian engines of 6 horse-power, and 100 fifty-volt 16 candle-power lamps. The brackets and pendant fittings are of a new and elegant design, those in the saloon and first-class berths being silver-plated, each fitted with its own combined switch and cut-out. The ship is also provided with deck lights, having a special contrivance for lowering into hold for loading and unloading cargo and embarking passengers at night. The installation was carried out by Mr. Robert Woodley, electrical engineer, of 248, Burdett-road, London.

CONSTANT CURRENT MOTOR-WORKING.—On the occasion of Mr. Wharton's lecture at Bath (referred to in our "Notes" of last week) an Immisch motor was run on the arc circuit lighting the theatre and part of the city. The circuit was composed of 30 arc lamps, two batches of incandescent lamps in parallels of 6, and the motor. The dynamo was a Thomson-Houston one, giving about 2,000 volts and 6·8 amperes. The motor was coupled by a belt to a two foot circular saw. The saw cut through some 4in. deals with ease, and 2in. and 3in. cuts were made as fast as the wood could be fed. The torque of the motor was regulated by a centrifugal governor, which varied the ampere turns in the field. The motor weighed 350lb. and absorbed about 350 volts at full load. This is, we believe, the first time a constant current motor has been run successfully on this side of the Atlantic.

CONTRACT OPEN AT LEON (SPAIN).—*Industries* states that the municipality of Leon offers a monopoly of fifty years for lighting the town with 260 glow lamps of 20 candle-power, burning each on an average 2,200 hours per annum, for the sum of £720. The contractor will be the only person allowed to fix cables or wires for the purpose of electric lighting, whether for public or private lights. No price is stipulated for private lighting. Tenders, which will be opened on the 6th August, are to be on the basis of a diminution of the number of years of the monopoly. Besides the lighting of the streets, the municipal offices are to be lighted by glow lamps of 20 candle-power, to be paid for at the rate of about 0·4d. per hour. The total number of lights likely to be used, including the theatre and private houses, will not exceed 600, but a price of 0·6d. per lamp hour would in all probabiltiy be obtainable.

MOTORS AND AIR PROPELLERS AT WHITELEY'S.—At Whiteley's, in Westbourne-grove, where there is a large electric lighting installation, some trials of electric motors of the Immisch type have lately been carried out with results of such a satisfactory character that it is probable that extensive use will be made of these machines. The new buildings in Queen's-road are already partially ventilated by means of a large Blackman air propeller, and we understand that it is in contemplation to make use of these propellers in connection with small motors instead of the punkahs which are at present at work in some of the departments. During the last few days a half horse-power Immisch motor has been in use for driving an ice-making machine, previously worked by hand. In six minutes the same amount of ice is turned out as previously required half an hour's grinding. The motor has so far been kept continually running from 6 a.m. to 7 p.m., and great satisfaction is expressed at its performance.

TELPHERAGE IN INDIA.—According to the *Indian Engineer*, the "telpher" system of lines is about to be introduced into India, but no details are given. Our contemporary proceeds: "It is stated that the right to erect posts in this country can be obtained for little or nothing, so that the cost would not exceed, say, Rs.7,000 per mile. It would most assuredly be a great convenience in our outlying agricultural districts, and would exactly meet the requirements of the cultivators; and furthermore would be extremely useful in connecting small towns with the nearest points on the main lines. In addition to the 'telpher' there is some talk of the application of electricity to tramways, &c., which apparently is the outcome of Mr. Reckenzaun's paper read before the Society of Arts. It is noteworthy that the water-power we possess from the Himalayas, distributed along our canals, will prove to be an immense advantage, but it remains to be seen whether it will assume a more definite form than discussion as at present."

FELTEN AND GUILLEAUME'S PRICE LIST.—An excellent plan is now being largely followed in making a price list largely available as a work of reference on the subject to which the firm in question devotes attention. In the recently issued catalogue and price list of Messrs. Felten and Guilleaume, the well-known wire makers, this practice has been followed, and we find a great deal of valuable information on the breaking strains of wire-ropes of various diameters and material. This information is conveyed in the form of a series of tables, and great pains have evidently been taken in the compilation. Perhaps in a subsequent issue Messrs. Felten and Guilleaume will see their way to enlarge the electrical sections of their catalogue by the addition of similar tables referring to the electrical constants of their wire. The lightning conductors of this firm made of stranded copper rope, and terminating in five-pronged spears of gilt copper, appear to adequately fulfil the conditions which the most recent theory has shown to be necessary.

ELECTRIC LIGHTING ON RAILWAYS.—The following paragraph appears in the *Lancet* of July 2nd:—"There are certain blunders of omission or commission in policy which appear inexplicable. One of these is the omission to light railway carriages by electricity, and another the recourse to gas and other highly dangerous appliances of illumination. The peril of travelling reservoirs of gas has been painfully illustrated of late. It is strange that any company has had, and still has, the hardihood to subject its passengers to the very grave peril which besets the use of gas in this way. More wonderful still is the neglect to use the motor force available for the self-generation and storing of electricity. Surely there would be no great difficulty in so adapting the necessary apparatus as to make the moving wheels of the carriage do the work of an engine. It is needless to emphasise this suggestion. There is, of course, nothing new in the idea, but it seems to be one of those very obvious matters which are seemingly too plain to be perceived, or in some way fail to impress that particular part of the mental constitution which we call the common-sense

Digitized by Google

instinct. The task of providing trains which travel at night with special accumulators cannot be overwhelming. Those trains that travel by day, and only require lights for tunnels could, we imagine, be utilised to charge the accumulators required by night trains."

THE TELEPHONE SIREN.—At the last meeting of the Berlin Electrical Society, Prof. Karsten described his telephone siren. The instrument (says *Industries*) consists of a disc, to the face of which are fastened radially small steel bar magnets. This disc is revolved by clockwork, and the pole of an ordinary Bell telephone, with diaphragm removed, is presented to the rim of the disc. The rapid passage of magnet poles induces currents in the telephone, and a musical note is produced in a telephone receiver connected with the siren. If all the magnets present the same polarity outwards, the number of complete waves produced during one revolution of the disc equals the number of magnets; if, however, the magnets are placed with alternating polarity, the number of complete waves is half that of the magnets, but the waves are stronger. In this case the tone heard in the receiver is the lower octave of the tone in the former case. It is also possible to arrange other combinations; for instance, if the poles are placed in the succession N N S, N N S, &c., the tone heard is the fifth of the former. Prof. Karsten has found that this combination gives tones most readily distinguished by the human ear, and he recommends it where this apparatus is to be employed for the measurement of resistances by the use of a telephone instead of the galvanometer in bridge tests. He finds that the sound given by the siren is more easily distinguished from accidental noises, which often accompany the employment of the usual make and break arrangement. By combining the siren with an anemometer it is possible to tell the strength of the wind from the tone produced in the receiver.

A "NEW FORM OF ELECTRICITY."—M. le Dr. Luce has made a very singular discovery—nothing less than "a new form" of electricity. This discovery was made by the learned doctor some five years ago, and has only now been communicated to the world through the medium of a brief letter in the columns of the *Bulletin de la Société International des Electriciens*. From this letter we may quote the principal passages (translating *verbatim et literatim*) which summarise the discovery:—"(1) In a conducting medium the formula of propagation is $I = I_1 - KD$; K being the coefficient of absorption of the medium, I the force at the distance D, and I_1 the initial force. (2) It follows the contour of a wire, but has a great tendency to propagate itself in a right line. (3) Its velocity is some metres per second. (4) Its conductors and its insulators differ notably from those of ordinary electricity; I have called it the *forme nervique* because its properties upon the whole closely resemble those of nervous propagation, if indeed they are not identical. (5) It can be developed by motion, heat, magnetism, or voltaic electricity. (6) The most practical method of evidencing its existence is the sensation which it produces in the hand, or the variation of temperature which it causes in a thermometer held in the hand. (7) I have employed this agent in the treatment of all forms of disease and for five years it has enabled me to avoid the use of medicaments amongst my numerous patients." On reading these closing lines some subtle association of ideas brings irresistibly before us the peaceful images of rural life, and we seem with startling clearness to hear the sound of the duck-pond and the poultry yard.

HARGREAVES' HOT-AIR ENGINE.—The annual report of the Chief Inspector, appointed under the Alkali Works, &c., Regulation Act, 1881, which has just been issued, contains the following:—"While this report is passing through the press a communication reaches me which has so important a bearing on the smoke question, and must be of such great interest to manufacturers generally, that I embrace the opportunity of inserting it. Mr. James Hargreaves, the well-known chemical manufacturer at Widnes, the inventor of the process for the manufacture of sulphate of soda which bears his name, has for several years been engaged on the production of a hot-air engine in which the energy of the fuel consumed should be much more completely converted into motive power than is the case in the steam engine of the present day. His efforts have so far been crowned with success that he can produce 30 indicated horse-power from a consumption of two gallons of common coal tar per hour. This, he adds, 'is the highest efficiency ever obtained by actual practice in any form of thermodynamic engine, and also the least costly. At present prices it is equal to 20 horse-power, or 1d. per hour.' The fuel may be gas tar, paraffin oil, or other liquid hydrocarbon, or it may be coal. In any case the combustion is far too complete to admit of the emission of black smoke. The combustion is carried on in a small but intensely heated chamber or furnace, the fuel being forced in under pressure. This is a step towards the removal of that large proportion of the smoke nuisance which is caused by the fire of steam boilers, and may be viewed as an approach to the fulfilment of Sir F. Bramwell's prophecy, that fifty years hence the steam engine will be regarded as an antiquated machine."

ESTIMATES OF RELATIVE COST OF ELECTRIC AND GAS LIGHTING.—Herr Oelwein, in a lecture to the Austrian Engineers' and Architects' Association, gives the following data as the relative cost of electric and gas lighting. His bases are:—gas burners, 16 candles, 4½ cubic feet; 7 incandescent lamps per horse-power; 150 lamps of either kind fitted up; price of gas 5s. 8¼d. per thousand cubic feet; sinking fund, &c., for electric apparatus 12½ per cent.; for gas fittings 10 per cent. The figures show the costs per hour in pence:—

Hours Consumption.		Incandescent.				Gas Light at 5s. 3½d. per thousand cubic feet.
		Steam engine.		Water-power existing.	Gas Motor.	
Yearly.	Daily.	Existing.	New.			
500	1·38	0·27d.	0·59d.	0·222	0·688d.	0·242
800	2·19	0·21d.	0·44d.	0·163	0 567d.	0·228
1,200	3 29	0·174d.	0·34d.	0·130	0·489d.	0·222
1,800	4.93	0·144d.	0·27d.	0·105	0·428d.	0·216
3,600	9·87	0·123d.	0·20d.	0 085	0·382d.	0·213

The *Gas World* adds to this as follows:—If the gas be 2s. 6d. per thousand cubic feet, we find that, on the given data (including the cost of gas motor, 22 horse, at £550, cost of incandescent lamps, &c., at £525. 8s., and cost of gas fittings at £150. 16s.), the cost per hour becomes:—

Hours Consumption.		Incandescent, with Gas Motor and Gas, at 2s. 6d.	Gas Light at 2s. 6d.
Yearly.	Daily.		
500	1·38	0·518d.	0·126d.
800	2·19	0·397d.	0·113d.
1,200	3·29	0·319d.	0·106d.
1,800	4·93	0·258d.	0·099d.
3,600	9·87	0·212d.	0·097d.

WHAT IS ELECTRICITY?—In another column will be found an abstract of an interesting paper read at a recent meeting of the New York Electrical Society by Mr. Townsend Wolcott. Mr. Wolcott's point of view is one which we confess commends

Digitized by Google

itself forcibly to our judgment. He dissents *in toto* from the idea that there is any objective or subjective necessity requiring that we should express "electricity" in terms either of matter or of energy. In fact, we are reduced in Mr. Wolcott's opinion to the statement that electricity is *sui generis*. Electricity *is*—electricity. Personally, however, we think that it must be admitted that we do not go beyond the limits of our knowledge of the facts if we venture the assertion that "electricity is a vehicle of energy." This may not help us very far as a definition, but the statement has the merit of implicitly containing a denial of the notion that electricity is a form of energy, while leaving open to discussion the more plausible idea that it is a form of matter. It is somewhat surprising that the demonstration that electricity is not a form of energy does not as yet appeal very strongly to all who might be supposed capable of appreciating the argument. Only a few months ago, in an important paper by M. G. Cabanellas, the opposite opinion was stated with much vigour, though with little or no argument in support of the assertion. "Some *savants*," said M. Cabanella—"even men of talent, who, however lack the true philosophical spirit—think that electricity is not a form of energy, and have tried to establish this view, it is needless to say in vain. The history of science contains in fact many of these chimerical notions where truth has been sacrificed to the taste for the marvellous." Thus M. Cabanella, to whom we would with due respect rejoin that

"There are more things in heaven and earth, Horatio,
Than is dreamt of in your philosophy."

Surely, one of the most impressive facts of modern science is found in the number and importance of the phenomena which we are still unable to express in terms of length, time, and mass.

THE BRITISH ASSOCIATION.—At a meeting of the local executive committee for the British Association, held last week in Manchester, the guarantee fund was reported as amounting to £10,345, a sum which is sufficient for the present without any further call on guarantors. The committee propose to provide space in the gallery of the Natural History Museum for the exhibition of instruments and specimens shown in connection with the sectional meetings. The Evening Entertainments Committee reported that the Mayor of Manchester had invited members and associates to a *conversazione* in the Town Hall on Tuesday, September 6th, and that the soirée kindly offered by the Executive Committee of the Royal Jubilee Exhibition had been fixed for the evening of Thursday, September 1st. It was stated that the lecture to working men, by Mr. George Forbes, F.R.S., on the evening of Saturday, September 3rd, would be on the electric light, and the Manchester and District Edison Electric Light Company (Limited) had undertaken the experimental illustrations in connection therewith. The Hospitality Committee reported that their efforts to secure the presence of eminent foreign men of science at the meeting had met with great success. Of those invited nearly 100 have already accepted, including Americans, Germans, French, Russians, Belgians, and men of other nationalities. Not merely will the numbers be altogether unprecedented, but in each of the leading branches of science the most eminent foreign representatives will be present. In physics, chemistry, and biology the attendance will be exceptionally large, and in these subjects the meeting is certain to produce permanent results of great value to science. The Excursions Committee reported that a list of thirteen excursions had already been arranged for Thursday, September 8th, the list including Chester, Chatsworth, Bolton Abbey, Hornby Castle, Crewe and Horwich Railway Works, Stonyhurst, and the Isle of Man. For Saturday, September 3rd, several excursions have already been arranged, including one to the salt-mines at Northwich, to Tatton Park, to Buxton, Knutsford, &c., and a marine dredging expedition will be made from Liverpool. At an influential meeting held at Leeds last week, under the presidency of the Mayor, it was determined to invite the British Association to that town in 1890.

THE SOCIETY OF ARTS.—TRIALS OF MOTORS FOR ELECTRIC LIGHTING.—In our issue of December 17th, 1886, we announced that the Society of Arts proposed to award two gold and two silver medals to the best motors for electric lighting purposes, and we printed the conditions of the competition at full length. The notice given was rather short, being only about two months, and it was intended to hold the trials in London in May or June of the present year. In January, however, the conditions were revised, and the trials postponed until May, 1888, while the time of entering for the competition has been extended up to 31st December, 1887. It is very much to be desired that this competition should be warmly entered into by the leading firms of engine makers, for if this should be the result we have no doubt that the trials will have a beneficial effect upon the electric lighting interest in general, as well as upon the important question of the best type of motor. We think, however, that it is to be regretted that the society has not seen fit to subdivide the classification of the engines still further. At present there are two classes, A and B. A consisting of "motors in which the working agent is also produced," such as steam engines with boilers, and gas engines with gas producers. Class B, consisting of motors to which the working agent must be supplied, such as steam engines without boilers, water and air engines, &c. From an electrical engineering point of view it would have been more to the purpose to have divided the motors in accordance with the requirements of the electric installation for which they were to be used; as, for instance (1) Engines for central lighting stations; (2) For ship lighting; (3) For large isolated installations; (4) For domestic installations; (5) For arc lighting. Some of which classes would perhaps bear still further sub-division. These various types of installation possess such varying requirements that it is impossible to select any one type of engine as the "most suitable for electric lighting" without further particularising. We much fear that these considerations, which are patent to every one interested, will operate to restrict the number of entries, and we would beg respectfully to urge the attention of the Society to the matter while there is yet ample time to reconsider the scheme. The revised regulations are nearly word for word the same as in the first issue, but have been extended to include air engines of all types, and engines working with any hydrocarbon liquid or vapour.

ELISHA GRAY'S TELAUTOGRAPH.—The following paragraph appeared in the Chicago *Tribune* of 25th June:—"Prof. Elisha Gray, of telephone fame, is perfecting an invention with wonderful possibilities, and one which promises great results. It has already reached that stage which ensures its practical success, the experiments thus far proving eminently satisfactory The 'telautograph' is the name by which the instrument will be known, which, by the way, conveys a very fair idea of what the instrument really is. Once in operation it will be possible for the Chicago speculator to deliver to his New York broker a telautographic order to buy or sell 1,000 or 10,000 shares of railroad stock, an exact fac-simile of the order being reproduced in that city at the same instant it is written here. If the Chicago man happens to be in New York and wants to send his wife a check for money, he simply writes it out in that city, and the moment he is through it is in his wife's hands:

Digitized by Google

here. The electric current, of course, is an important factor in the invention, but the chief feature is the plate or instrument on which the writing is done. No particular kind of pen or pencil has to be used; in fact, a sharp-pointed instrument of any kind, or even a piece of wood, will answer the purpose. The paper on which the writing is done and the autograph reproduced does not have to be prepared, for in the first instance it is the pressure on the plate which gives the impulse to the machine, while the reproduction is brought about by a tracing point, which may be a properly-inked pen or even an ordinary lead pencil attached to a movable arm in the receiving machine at the other end of the line. A number of experiments with the machine have been made at Highland Park, where Prof. Gray's laboratory is, all of them of the most satisfactory character. The circuit was not a very long one, but the tests were of that kind which indicated that the length of the circuit did not matter much and that the work could be done over 1,000 miles of wire as perfectly as over 100. Prof. Gray has not yet applied for patents on the invention, but it is fully covered by caveats, so that he has removed the injunction of secresy and feels free to talk upon the subject with his friends. He is inclined to think the machine will be required in all cases where absolute accuracy in the delivery and filling of an order is required, and that it will eventually supersede the present system of telegraphic communication; in fact, that an operator will simply transcribe a message, and, while in the act of so doing, will wire it to any point on the continent, the reproduction at the other point always being a fac-simile of the writing of the person at the machine."

THE RECREATIVE EVENING SCHOOLS ASSOCIATION.—We would invite the attention of our readers to the interesting and important work in the spread of elementary scientific knowledge which is being carried out in London by the Recreative Evening Schools Association. The object aimed at by the Association, of which the Princess Louise is president, and which is actively supported by men of eminence in science, art, and literature, is, in brief, to carry the education of the children of the working classes to a stage of culture beyond that which is obtained in the Board Schools. The scheme is applicable to not less than 400,000 London children, and is dependent solely upon the voluntary help of those who interest themselves in the work. We need say nothing to commend the work of the Association to the sympathy of our readers, and there are doubtless some who will be glad to render active assistance. The Science Committee of the Association, consisting of the following gentlemen, H. G. Rawson, Esq., chairman; W. Lant Carpenter, Esq., C. D. Barker, Esq., Le Blanc Smith, Esq., Prof. F. Jeffrey Bell, F. W. Rudler, Esq., J. J. Harris Teal, Esq., J. Edward Flower, M.A., secretary, has recently issued the following circular letter:—"Lectures on Elementary Science.—The following is the list of subjects selected for courses of Simple Science Demonstrations, with or without lantern illustrations, in evening schools in winter. Each course to consist of ten or twelve lectures of a thoroughly popular but educational kind. Each lecture to be of about 45 minutes' duration. The scholars range from 13 to 18 years of age. The proposal is that each lecturer should give the whole course of lectures on the subject he may select, and in the same school or neighbourhood, in consecutive weeks. About 50 lecturers will be required, in order to supply all the schools. Any gentleman willing to give help is invited to send his name and address, the branch of science he professes, and the locality in which he would prefer to teach, to the secretary at the above address. List of subjects for lectures: *A. Chemistry and Physics*—I. Chemistry (Inorganic). II. Physics. 1. Elementary mechanics and pneumatics. 2. Elementary physical properties of air and water. 3. Sound. 4. Light. 5. Heat. 6. Magnetism and electricity. 7. Physical astronomy. *B. Biology*—1. Elements of animal physiology. 2. Elements of vegetable physiology. 3. Structure of leading forms of animal life. 4. Structure of leading forms of vegetable life. *C. Geology and Physiography*—1. Physical geography. 2. Stratigraphical Geology:—The history of the earth revealed by the stratified rocks. 3. Palæontology:—Leading forms of extinct life; fossils, coal, &c." Communications should be addressed to the secretary, at 37, Norfolk-street, Strand, W.C.

OPTICAL DEMONSTRATION OF THE ACTION OF THE TELEPHONE.—The following abstract of a paper in the *Electrotechnische Zeitschrift* is taken from the number of the *Proceedings* of the Institute of Civil Engineers which has just appeared:—"The mechanical movement of the diaphragm of the telephone, if actuated by powerful currents, can be shown by the nodal lines formed by lycopodium dusted on its face; but if the current be generated by a microphone or by another telephone actuated by singing or speaking, not a trace of a Chladni's figure is produced. By affixing a small mirror, however, between the centre and circumference of the diaphragm, and reflecting therefrom a beam of light on to a distant scale or telescope, its motion can be detected; but for a lecture demonstration the best method for exhibiting this motion is to fasten a stretched wire to a projection on the centre of the diaphragm, and fix a mirror longitudinally on the wire between a loop and node, by which means a movement of 18 inches or so can be given to the spot of light on the scale; the form of the vibration is, of course, not reproduced in this latter instance. If mirrors be fixed to both the actuating and receiving instruments, the beam, after reflection from both being thrown on a screen, as in Lissajou's method, the figures observed afford a most simple means of illustrating the deformation of the musical notes or vocalisation which results from the action of the diaphragm itself. For the most accurate examination of the movement of the telephonic diaphragm the author has adopted König's method of dancing flames analysed by a rotating mirror, and outline diagrams of the different forms of the vowel sounds as sent and received, revealed by this method, are given. The effect of the introduction of electrical resistance, capacity or self-induction in the circuit, as regards the alteration and interconfusion of the different vowels or consonants, is thereby clearly revealed, and is due not so much to reduction of the intensity of the sound as to the rounding off of the current-waves. The permanent record of these flames could not be photographically produced with ordinary gas, but a certain degree of success followed the use of bisulphide of carbon vapour burning in nitrous oxide gas, as by this means the maxima or ridges of the flames were clearly developed, though the minima or furrows were somewhat indistinct. The author proposes the application of this method for testing dynamo machines, as by it can be seen the actual progress of the phase in the alternating current, or the impulse at the passage of the brush over each commutator plate in the continuous current. It could also be conveniently applied for chronographic measurements—*e.g.*, the velocity of projectiles in the gun tube; let the shot contain an iron bar, and the gun be surrounded by a series of coils which are in connection with a telephone and some source of electric current; then the time of the passage across the plane of each coil can be actually recorded on the photographic plate, the great advantage of this method lying in the fact that the gun tube need not be tampered with, and that one or two sets of coils would suffice for guns of any calibre."

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 138.)

We come now to the field-magnets. The degree of saturation assumed in the armature core was $\sigma = \frac{20}{25} = \cdot 8$, and taking as average iron for the magnets that which is practically saturated at eighteen lines per square inch, and making $\sigma_1 = \sigma$ we proceed to find the section of the cores.* First, however, it is necessary to know the value of ρ, the resistance of the air leak. Unfortunately the writer of these papers has not got any experimental figures on which to base this quantity, excepting for four-pole machines of the new Gülcher type, and for two-pole machines having side cheeks and standing poles downwards.

In these last-named, the numerator constant was 355, but in such a machine as the one under consideration this value will be too small, because the leakage emanates from a much smaller surface; it will also greatly depend on which way the machine is set on the bed plate, the least leakage taking place when the poles stand upright away from the bed-plate. In such machines Mr. Kapp has found 500 to be a fairly approximate constant to use, but since the more general practice is to place the poles downwards, as in the Edison-Hopkinson machine, we will take 400 in the present case.

The magnetic resistance of the armature core must now be found. It is expressed by the fraction $\frac{\text{mean length}}{\text{cross section}}$, the factor 2 being omitted because the lines pass through the two sides in parallel. Thus

$$R_A = \pi \frac{\left(R - \frac{p}{2}R\right)}{p q \gamma R^2} = \frac{3 \cdot 46\pi}{17 \cdot 12} = \cdot 636.$$

The total number of lines passing through the armature core is

$$Z_1 = \frac{117 \times 10^6}{174 \times 1000} = 672,$$

that is 336 passes through the area 17·12; the density is thus

$$\sigma_1 = \frac{336}{17 \cdot 12 \times 25} = \cdot 785.$$

The discrepancy between this figure and ·8, which was originally assumed, is due to the practical necessity of adjusting R to the English measurement of $4\frac{5}{8}$in.

The coefficient of saturation will now be

$$K_1 = \frac{\tan \frac{\pi}{2}\sigma_1}{\frac{\pi}{2}\sigma_1} = 2 \cdot 3$$

The real resistance of the armature core is therefore $K_1 R_A = 1 \cdot 46$.

It must be remarked that this figure is undoubtedly higher than it should strictly be, because we have here considered the mean length of the passage through the core as represented by a complete semi-circle drawn halfway through its thickness, but the error is probably small, and is, moreover, on the right side. In the same way the cross section of the air space δ will be considered to correspond with the core surface of equal angle with the pole shoe. The clearance between the outside of the winding and the interior surface of the pole shoe, which is necessary to mechanical safety, depends very much on the quality of the workmanship expended in the winding. When the core is made up perfectly true and the winding is carefully performed it need not be more than $\frac{1}{8}$in. in an armature of 1ft. in diameter.

* With reference to the discrepancy between the practical saturation density of iron in armature and field-magnet cores, it may be noticed that the experience which has led Mr. Kapp to limit the saturation of the external field to 18 lines per square inch is fully in accord with the experiments by Prof. Ewing, who found that far higher inductions could be obtained in comparatively small masses when placed in heavy fields than when directly excited.

It is generally held that in practice this quantity is far nearer a constant than a simple linear function. This, however, is not the author's experience; on the contrary, the clearance always has to increase with the dimensions, and for all but exceedingly small machines this variation can most suitably be made to take place strictly with the linear dimensions.

By the rule given above, the clearance in the present machine would be ·096, let us say ·1, which, added to the depth of the single layer on the outside of the core would give $\frac{\cdot 11}{\mu} + \cdot 1 = \cdot 26$.

The angle covered by the shoe must not be so great as to cause an excessive leakage of magnetic force across the space intervening between opposite poles; 135° will be a maximum in two-pole machines, and about 55° in those with four poles.

The pole surface will thus be

$$\frac{135}{360} \cdot 2\pi R \cdot q R = 101;$$

the air resistance is therefore

$$R_a = \frac{1440 \times \cdot 52}{101} = 7 \cdot 41.$$

The exciting power p_1 necessary to force 672 lines through the resistance $K_1 R_A + R_a$ is thus

$$672 \times 8 \cdot 87 = 5950.$$

The leak z which will take place under this pressure is

$$z = \frac{p_1}{\rho} = \frac{5950 \times 9\ 25}{400} = \text{say } 138.$$

The total number of lines which pass through the field-magnets are therefore $z_2 = 672 + 138 = 810$. Assuming practical saturation at 18 lines per square inch, and $\sigma_2 = \cdot 8$, we have the section of core

$$AB = \frac{810}{18 \times \cdot 8} = 56.$$

The length of armature core $q R = 9\frac{1}{4}$in. Thus the short diameter of the magnet section will be

$$\frac{56}{9 \cdot 25} = 6\ 05\text{in.}$$

and the depth of winding

$$\frac{6\ 05}{4} = 1 \cdot 51; \text{ say, } 1\tfrac{1}{2}\text{in.}$$

It is always best to make the magnet bar in two or more pieces, so as to assist the ventilation as much as possible. In the present instance two bars, each $4\frac{1}{2}$in. × $6\frac{1}{4}$in., set edgeways, with $\frac{1}{4}$in. between them, would constitute a good arrangement; the perimeter would then be $2(6\frac{1}{4} \times 9\frac{1}{4}) = 31$in., which may also be taken as the number of square inches of surface per linear inch of core, and as the watts per linear inch of winding. In modern compound-wound dynamos the shunt current is, as a rule, about $\frac{1}{20}$ of the main current, and the shunt winding constitutes about $\frac{3}{4}$ of the total exciting power. The number of turns in the shunt winding will thus be about 60 times as many as in the series, and the average current in the whole winding will be $\frac{1}{15}$ of the total current. The above rough estimate is based merely upon the average value of shunt current in machines of ordinary dimensions, and it is made in order to furnish the first datum for finding μ.

Of course, the same remarks which were made with regard to this quantity in dealing with the armature winding apply here also, and it is necessary to make a preliminary assumption for the section of wire A on the basis of its conveying the current $\frac{105}{15} = 7$ amperes. Suppose we fix the density provisionally at 1,200 amperes per square inch, the section $A = \frac{9}{1200} = \cdot 00583$, and the diameter of a circular wire of corresponding area = ·086in. Then for this circular wire

$$*\mu = \cdot 885 \times \frac{\cdot 086}{\cdot 086 + \cdot 02} = \cdot 72.$$

* In magnet winding with circular wire ·02in. is the maximum thickness of cotton.

Digitized by Google

Turning now to the equation $\frac{d\,l\,\mu^2}{162\times10^4\times A^2}=\frac{w}{C^2}$ given on page 27, Vol. XIX., we have $d=1\cdot5$ and $l=31+1\cdot5\pi=35\cdot72$in.; we thus get A = ·00521 sq. in., which gives $\mu=\cdot71$—assumed at ·72. For future machines of this type A will be at once known from the equation

$$\text{density}=a\,L^{-\frac{1}{2}}$$

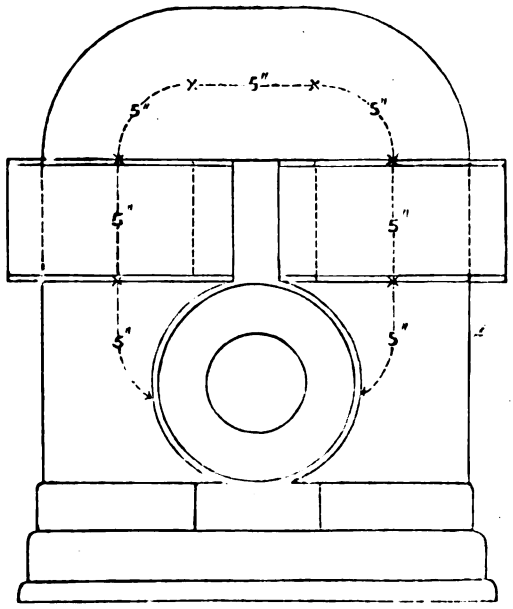
where L is one dimension of the core section and a is a constant; μ can then be taken out of the equation direct.

The number of turns per inch will be

$$n=\frac{\mu^2\,d}{A}=\frac{\cdot505\times1\cdot5}{\cdot00521}=146.$$

It now only remains to determine the total exciting power P in order to complete the dimensions of the magnets. To do this it is necessary to find the magnetic resistance R_F, and we must therefore assume some length for the winding as a first approximation.

The length L on which R_F depends consists of three parts, the mean path of the lines through the yoke, the length of the exciting bobbins, and the mean path of the lines through the pole shoes. Referring to Fig. 13 it will be seen that in our design the first length equals $5+3\cdot125\pi=14\frac{7}{8}$in., and the mean path through the pole shoes will be about 10in. in the



Scale—One-eighth of full scale.

Fig. 13.

two sides. An average length for the winding on such a machine would be about 5in. for each bobbin, and assuming this length provisionally we get a total length of $34\frac{7}{8}$, or, say, 35in. Then $R_F=\frac{70}{56}=1\cdot25$, which, multiplied by 2·45 (since $\sigma_2=\cdot8$ and $\therefore K_2=2\,45)=3\cdot05$; thus $p_2=810\times3\cdot05=$ say, 2500, and $P=p_1+p_2=8450$. For the purposes of designing the carcase of the machine, it would be safer to increase this figure a little and say P = 9000; we then get the length of winding as

$$\frac{P}{2Cn}=\frac{9000}{2\times7\times146}=4\cdot4\text{in.}$$

The thickness of the cases and end insulating washers will just make up the 5in., so that the value for R_F will remain correct.

Having now arrived at all the dimensions of the proposed machine, it is possible to draw the characteristic curve of total E.M.F. by assuming various values for P between 9000 and zero, and then calculating the corresponding E.M.F. for each by the formulæ already given. Since it has been necessary at several points to accept a probable approximation in place of experimental data, it is not to be expected that a curve so drawn should coincide with the experimental curve so closely as would be the case were all the data obtained from actual observations with a machine of this type. If the character of the curve be correct, however, the machine may be compounded directly from it, and the only necessary adjustment, if any, will be one of speed. Of course in practice on any large scale it is generally preferable to experiment with a spare set of bobbins before attempting to calculate the relative strengths of the shunt and series winding; but still cases sometimes occur where it would be of great convenience to determine them at once.

To do this it is only necessary to take such an exciting power p on the line O X as will give the required E.M.F. on O Y, since on open external circuit the slight fall of potential due to the resistance of armature and series winding, and also the self induction, may be neglected. Then $p=\frac{E}{r_s}.n_s$, where E is the E.M.F. required on open circuit, and n_s and r_s the number of turns and resistance of shunt winding respectively.

Thus $$\frac{n_s}{r_s}=\frac{p}{E},$$

also $$r_s=\frac{\text{length}}{162\times10^4\,A_s}=\frac{2\times l_s\times n_s}{162\times10^4\,A_s},$$

where l_s is the length of a mean convolution; whence

$$A_s=\frac{2\times l_s\times\frac{p}{E}}{162\times10^4}$$

all of which quantities are known.

With regard to the number of turns it may be remarked that since the resistance r_s varies directly with n_s, p will remain constant providing that no variation occurs in l_s; in practice, therefore, after having wound on the series wire, the magnet case is filled up with the shunt winding. In calculating the series winding it must be remembered that the exciting power due to the shunt will increase in direct proportion to the E.M.F., so that if, as is usually the case, a higher E.M.F. is required with full load than on open circuit, a proper allowance must be made for the increased shunt power.

(To be continued.)

INCANDESCENT LAMP MANUFACTURE.—XX.

BY J. SWINBURNE.

Testing.

The first thing to test is the vacuum. The usual way is to pass the spark from an induction coil through. If one terminal of a Ruhmkorff coil, giving about a half-inch spark, is connected to the terminal of the lamp, and the other is led to a wire tied round the bulb, and the lamp gradually exhausted, the discharge is purple or lilac at first, with pinkish lights round the carbon. As the vacuum gets better the discharge becomes bluer, and if the bulb is made of German glass it gradually changes to bright green. The green is distributed through the bulb at first, but as the vacuum gets better it is confined to the internal surface of the glass; it then appears only in patches on the glass; and finally it disappears altogether. It is difficult to get it to disappear altogether. If the bulb is made of English or lead glass the discharge is never of the brilliant apple-green seen in the case of German glass; it is of a bluish colour till it disappears.

The primary coil need not be supplied by a primary battery, as the cells are very troublesome. It is best, therefore, to connect it with a dynamo and resistance, or to work it from a secondary battery. If it is put in circuit with a dynamo with resistance in series to reduce the electromotive force, a lamp should be put in shunt to the primary coil and contact breaker, otherwise the sparking is troublesome and soon destroys the contacts. One terminal of the secondary is led to a plate and the other to a loop about an inch off, so that when the lamp is taken by the tip and held in the loop the

Digitized by Google

terminals touch the plate. In testing lamps with very thin or weak carbons it is best to take the lamp in the hand and touch one terminal of the coil only, as, if the lamp has a powerful discharge passed through it the carbon is often broken. Sometimes the carbon remains some minutes stuck against the glass after the discharge. Lamps will also frequently glow in the dark after the discharge.

A large number of lamps can be tested for vacuum very quickly. Those which do not show either a bright apple green on the glass if German, or no discharge at all, are rejected. Any rejected lamps are examined; if there are any cracked at the sealing in they are sent back to the glass blowers' room to be repaired if possible. To repair such a lamp, the nose is held for a moment in the blowpipe flame, which cracks it. The lamp is left till the vacuum is destroyed by the slow leakage thus produced. The nose is then knocked off, and a new exhausting stem is sealed on. It requires some practice to do this neatly, but with care a lamp may be repaired so well that no one could tell it had been exhausted twice. The cracked end is then very slowly and carefully heated and worked till the crack is gone. The lamp is then sent to the pump room in the usual course. If the lamp is merely badly exhausted, a new exhausting tube is sealed on, and the lamp pumped again.

The current opinion is that the vacuum in a fairly well exhausted lamp is about one in a million, and that the Ruhmkorff coil is an infallible means of testing the vacuum.

The writer has come to the conclusion that this is not the case, and that the vacuum generally obtained is not more than about 1 in 20,000. The whole question demands further experiment, as the results obtained so far are conflicting, and there are not enough data to draw conclusions with certainty. In the first place, mercury vapour must have some tension. It seems to have been generally assumed by those who have worked at high vacua that it has no tension. Regnault found the vapour tension of mercury at 20°C.—which may be taken as the average temperature in a pump room—to be ·0372 mm.; this would give 1 in 20,000 as the maximum vacuum obtainable by any mercury pump. Apart from Regnault's determination, the mercury must have an appreciable vapour tension, for it evaporates perceptibly at ordinary temperatures. If a piece of gold leaf is held near mercury it is soon amalgamated. It seems, therefore, probable that the mercury pump ceases to take out air when the pressure is about equal to that of the mercury vapour itself. This would show why a Geissler pump goes on taking air out after a Sprengel stops, as the mercury in a Sprengel, being violently broken up, would give off vapour more easily. The action of the pump would of itself lead one to suppose that some such action takes place. If a Geissler pump, with a bulb the same size as, say, one lamp and the phosphoric and other tubes were set to exhaust the lamp, beginning with a pressure of 10 mm. of mercury, it would reach a vacuum of 1 in a million in 14 strokes, if the glass gave off no air. The glass, of course does give off air, so the pump takes considerably longer. But if the pump really brought the vacuum up to one in a million, it is not likely that the gas would be given off gradually, so that the vacuum soon rose to one in 200,000 or 300,000, and then rose to one in a million very slowly, never getting much better. If the Geissler is worked till it shows a vacuum that would generally be called one in a million, and then left for some hours, the vacuum will apparently have fallen to about what would be called one in 100,000. Even if the lamp be heated very strongly and be pumped for several days, it will show a so-called vacuum of only one in 20,000 or so after standing, though it showed one in a million at the last stroke of the pump. When a Geissler pump is worked till it shows a so-called vacuum of one in a million, it goes on for some time with only slight improvement of the vacuum. If the vacuum were really one in a million or so, and the air delivered by the pump were approximately equal to the air coming off the glass, which is the accepted theory, the vacuum would immediately fall to one in 500,000, if the pump were allowed to miss a stroke. It does not do this, however; the apparent vacuum falls very slowly. This is easily explained on the mercury vapour theory, as the bulb of the pump would be nearly full of mercury vapour, a little air coming in to every stroke, so that the apparent vacuum would increase very slowly. If the pump is left for some hours the air would diffuse into the pump bulb, and the mercury vapour would also find its way into the phosphoric tube and lamp. This would also explain why the apparent vacuum should fall off so much when the pump is allowed to rest for a day or so.

To return to the spark from the induction coil. It has been already mentioned that no spark will pass through the bulb of a good Geissler pump while the mercury is descending, until the end of the tube from the lamp is uncovered. It was known in the last century that pure mercury vapour does not carry any spark. A Torricellian vacuum was made, the mercury having been very thoroughly boiled in the tube. It was found that the spark from an induction coil did not pass. When a little air was admitted, however, the bright green light appeared at once. Mercury vapour, therefore, contrary to the statements generally made, will not pass a spark unless air is mixed with it. As already mentioned, mercury seems to sweep the air off the glass, so that the Geissler bulb contains pure mercury vapour when the mercury is descending, but the spark can pass immediately the end of the lamp tube is uncovered.

Another way of testing vacua, which is only applicable in experimental work, when the lamp is not wanted, is to open the bulb under mercury. It requires care to perform this operation properly. If a lamp is merely held with its nose under mercury, and if the nose is then broken with a pair of pliers, the mercury will leave a bubble of air about the size of a bean. Most of this has come in from the outside, as there is a film of air upon the outside of the lamp, and especially on the jaws of the pliers. If the nose be broken so as to make a very small hole, and if the jaws of the pliers or any such thing be held against the tip, bubbles of air will be seen to come into the lamp. The best way to prevent this source of error is to wet the lamp and pliers with water or oil. If a number of lamps which have broken terminals, or are wasters from some other cause than bad vacua, are taken and tested with the induction coil, and are then opened under mercury, it will be found that those which showed what would generally be considered the best vacua on the coil do not always show the least air when opened under mercury. The air bubble generally left when a lamp is opened under mercury would correspond to a vacuum of about one in 10,000 to one in 20,000; but sometimes the mercury fills the whole of the inside of the lamp, showing a perfect vacuum. It is probable that the air condenses against the glass, and that this test is of little or no value. Davy found that when the mercury was allowed to rise to the top of a barometer tube slowly it left a bubble, but when it was allowed to come up with a bump, the bubble did not appear and the air seemed to be flattened out against the glass.

Sometimes a lamp passes no spark, or shows bright green spots after it has been lying in the store for some time, but after running it will show a much lower vacuum on the coil. If left for some time the vacuum will appear to improve again. It seems as if the gas inside condensed on the glass, and was driven off by the heat when the lamp was run. The passage of sparks also seems to bring off gas from the glass. This effect may be best observed while exhausting a lamp. The vacuum of the lamp can also be apparently reduced by merely heating it.

Sometimes lamps, especially those for high electromotive force, or badly exhausted, show a blue light flickering about on one end of the carbon. There is a curious phenomenon in connection with this blue light. If a lamp which shows it is run still brighter the blue light generally gets worse and leaves the terminal, and spreads until the whole of the inside of the lamp becomes filled with bright blue light. If the lamp is overrun for some time, the blue light begins to flicker, and the flashes get fewer till there is only an occasional flicker visible. Finally it disappears altogether. It cannot be made to appear again.

If the lamps are run on the pumps, any that show blue lights during the testing should be rejected and sent back for re-exhausting; but if they are not run on the pumps, lamps

Digitized by Google

for high electromotive force will occasionally show blue lights, which disappear at once and may be disregarded if the lamps show green phosphorescence on the induction coil.

The whole question of high vacua and the adhesion of air to the glass demands thorough investigation. Bunsen is of opinion that carbon dioxide is dissolved by the film of water on the surface of the glass, and that, though solution of carbon dioxide in water at ordinary pressures does not act on glass, still the capillary attraction exerts such enormous pressure that a sufficiently strong solution is made to act on the glass, forming carbonate of soda.

The writer hopes to be able to carry out some further experiments on high vacua within the year, and if they prove worth it, to publish any results that may throw light on the difficult question.

SOUTH KENSINGTON.

EXAMINATIONS OF THE SCIENCE AND ART DEPARTMENT.

The following were the questions set at the recent examination in Subject IX., Magnetism and Electricity; Examiners, Prof. G. Carey Foster, F.R.S., and Prof. A. W. Rücker, F.R.S.

General Instructions.—(If the rules are not attended to the paper will be cancelled.)—You may take the elementary, or the advanced, or the honours paper, but you must confine yourself to one of them. Put the number of the question before your answer. You are to confine your answers strictly to the questions proposed. Your name is not given to the examiners, and you are forbidden to write to them about your answers. The examination in this subject lasts for three hours.

First Stage or Elementary Examination.

Instructions.—You are not permitted to attempt more than eight questions. You may select only two in magnetism, three in frictional electricity, and three in voltaic electricity. The value attached to each question is the same.

Magnetism.

1. A small magnet is placed upon a flat cork which floats in a basin of water, and it is fastened to the cork with a little wax. Describe and explain the behaviour of the magnet (1) when under the influence of the earth's magnetism alone, (2) when an artificial steel magnet is brought near to it.

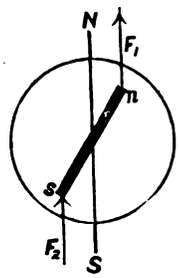


Fig. 1.

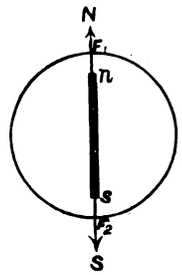

Fig. 2.

Answer.—When under the influence of the earth's magnetism alone the cork will come to rest with the needle in the direction of the magnetic meridian and with its north-seeking pole pointing northwards, but it will have no tendency to move bodily in any direction.

The reason of this is that the forces F_1, F_2, exerted by the earth's magnetic field on the two poles of the needle in any position, as n s, Fig. 1, are equal in magnitude, and act in opposite directions parallel to the magnetic meridian, thus forming a couple tending to turn the needle about its centre until it comes into the magnetic meridian, as in Fig. 2, when it will remain at rest, since the forces F_1 and F_2 are then oppositely directed in the same straight line, and therefore have no resultant effect.

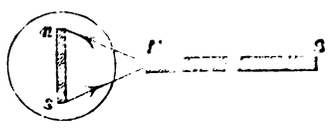

Fig. 3.

When a steel magnet is brought near to the floating needle, it will overcome the influence of the earth's magnetism, and its nearer pole (N in Fig. 3) will exert a stronger force than its more remote pole, will repel the similar pole of the needle and attract

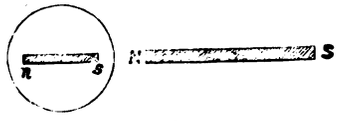

Fig. 4.

the dissimilar pole, causing it to turn with its dissimilar pole towards the near pole of the magnet, as in Fig. 4, and then the dissimilar poles being nearer than the similar poles, the attraction will be greater than the repulsion, so that the cork will move bodily towards the magnet.

2. A compass needle and a straight strip of soft iron of the same length as the compass needle are fastened together so as to be in contact with each other at both ends. Will the force which tends to make the combination point north and south be the same as that which would act on the compass needle alone? Give reasons for your answer.

Answer. The compass needle N S (Fig. 5) will act inductively on the iron, magnetising it oppositely as shown in the diagram, and

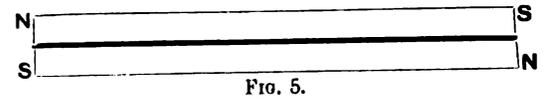

Fig. 5.

the earth's magnetism will act oppositely upon the adjacent poles of the compass needle and the bar of iron, but more strongly upon the compass needle, since the induced magnetism of the bar will be less than that of the compass needle. Therefore the forces acting on the ends of the combination, being equal to the sums of the forces acting on the two component parts, will be in the same directions, but smaller in amount, than those originally acting on the compass needle.

3. How would you construct an astatic needle out of a uniformly magnetised strip of watch spring, which you are allowed to bend or break as you please?

Answer. Break the watch spring in the centre, so forming two magnets of equal strength. Fasten them rigidly together by means

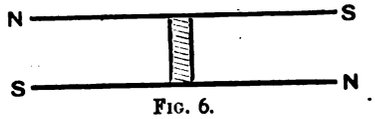

Fig. 6.

of some non-magnetic substance, with their axes parallel, and their poles in opposite directions, as shown in Fig. 6.

Remarks. We should note that such a combination, if it could be made exactly as stated, would form an absolutely astatic needle, viz., one on which the earth's magnetism would have no effect whatever, so that if it were to be used as a galvanometer needle, it would either have to be suspended by two threads close together (bifilar suspension), or by a fine wire or glass fibre, whose torsion would be sufficient to give it a definite direction.

In practice, however, it would be very difficult to ensure such absolute equality in the two portions, and even if once attained, the slightest change in the magnetisation of one of the strips relatively to that of the other would destroy the absolute astatic property of the combination, and enable the earth's magnetism to exert a slight directive force upon it, setting it in the normal direction of the stronger strip.

4. If a compass were carried round the equator, would it point in the same direction at all places? If not, state, as nearly as you can, what changes would be observed in its behaviour during the journey.

Answer.—It would not point in the same direction at all places. Starting from the east of South America and travelling eastwards, it would have a westerly declination, increasing from zero to a maximum, and diminishing again to zero at a point in the Indian Ocean; and continuing our journey round the equator it would have an easterly declination, increasing as before from zero to a maximum, and diminishing again to zero on returning to the starting point. The points of maximum declination would be about midway between the points of no declination.

(To be continued.)

A Simple Method of Multiple Writing by Electricity.—Some few years ago, at a time when there was a rage for all kinds of apparatus for multiplying facsimile copies of handwriting, it will be remembered that Edison brought out an ingenious "electric pen," in which a small needle darting to and fro at great speed made minute perforations in the paper, the printing being effected by an inked roller which was run over the perforated paper like a stencil plate. The movement of the needle was produced by means of a tiny magneto-motor mounted upon the style and driven by a couple of bichromate cells. The cells had, however, to be of large size, the motor requiring a good deal of current. Moreover, it was impossible to write very fast with the pen in the first instance, owing to its weight and the necessity for holding it in a vertical position. Recently, M. Garel has succeeded in obtaining similar results by more simple means. He writes with an ordinary black lead pencil upon very thin paper, which is laid upon a smooth carbon block. The lead of the pencil is connected to one terminal of a small induction coil, and the carbon block to the other terminal. A spark then follows the pencil point, and the paper can be used as a stencil. We do not know what amount of battery power or what size coil is actually required in this process, but the experiment is an interesting one, even if not of much practical value.

PROGRESS OF ELECTRIC RAILWAYS.

The comparative statistics which appeared in our columns a fortnight ago relating to ELECTRIC RAILWAYS now actually at work in Europe and America enable us to review with some degree of confidence the progress which that system of locomotion has made during the past two or three years. The tabulated statement furnished by Mr. COMMERFORD MARTIN to the American Institute of Electrical-Engineers carries us back to the year 1881; but in reality the lines then attempted or constructed were merely experimental and tentative; and it was not till 1884-5 that serious efforts were made to develop electric railroads on the commercial basis, which those earlier experiments had by that time proved to be possible. Taking, then, the middle of 1884 as the new departure, the number of lines constructed down to the beginning of the present year is very remarkable and highly encouraging. Mr. MARTIN'S table does not profess to be in all respects exact; and in regard to some undertakings of the kind referred to, it is by no means complete. But it would appear that the first permanent electrical railroad was laid down at Lichterfelde, Berlin, in 1881, over a distance of 1½ miles, and that it has been carrying passengers at the rate of 100,000 annually ever since. At Zankerode, in the same country, a shorter line, on the overhead conductor principle, was constructed for mining purposes in the following year, and is said to be carrying about 300 tons of material daily. In the year following, the well known line at Portrush, six miles in length, and the one mile railroad on the Brighton beach came into operation, the former being worked primarily by water-power, and a third rail for conductor; the latter by a gas engine, the ordinary rail track acting as conductor.

Upon these beginnings it may be said that all the later electrical railroads and tramways have been modelled. The success of the Brighton line was not less than that of the line at Berlin; and this was soon followed by a perhaps still more profitable undertaking at Blackpool, which is said to have carried a million passengers in little over two years. The conduit system for the conductor is, as our readers are aware, employed on the two-mile line at Blackpool; and when we have said this we think we have exhausted all the elements of novelty introduced down to the beginning of last year, when storage batteries were tried for some time on the Hamburg tram lines. The experiment at Hamburg has been followed at Brussels in the present year; but whether or not the general result of this new departure be as hopeful as Herr HUBER would have us believe, it is clear that the storage system has not yet found favour in America, where the methods which have proved so successful in England and Ireland have been closely copied. Nevertheless, considerable interest is being taken at the present time in America in the use of secondary batteries for traction purposes, and several lines will shortly adopt this principle. Electrical locomotion in the States, however, did not make a start till 1885; but in the two years since then there have been at least a dozen electric railroads constructed, some of them of considerable extent—that at Montgomery, Ala., being 11 miles long. Most of these lines are for passenger traffic, and the yearly freight ranges from 200,000 to 500,000 persons. It is noteworthy, however, that on the longest line just alluded to extra cars have been added to the two with which the line started in 1885-6, and it is now carrying passengers at the rate 1,000,000 annually. As a rule the prime power is supplied by steam, but in several instances the motors are operated from electric lighting stations, which thus do duty for both illumination and locomotion purposes.

Here it will be observed the Americans are ahead of us. Probably this may be attributed to the price of gas being higher in the States than in England. But we call attention to the fact in order to point out that the electrical power required here for locomotion might in some cases serve for the purpose of illumination, just as in the States the electric light plant has been utilised for supplying locomotive power. There are two or three projects on foot just now for fresh underground railways in the metropolis. It would be an immense boon to travellers by these subterranean tunnels if electricity were employed, both for the motive power and for lighting. Either the tunnels themselves or the cars ought certainly to be lit by arc or incandescent lamps; and this could be most economically effected if the trains were also worked electrically. Moreover, it is not difficult to see how easily this arrangement would lend itself to the lighting of the district covered, or rather undermined, by the proposed railways. The conductors in the tunnels might be tapped at suitable intervals, and a system of electric lighting established above ground, which would greatly help to pay the cost of the electric locomotion below. It is to be hoped that electrical engineers are alive to these facts, and that some strenuous efforts may be made without delay to induce the promoters of the new underground railroads, all of which are far away beyond the reach of daylight, to consider the electrical possibilities here suggested.

On the economical side of the question we need not particu-

Digitized by Google

larly dwell. The figures supplied both by Mr. MARTIN in regard to electric railroads worked on the American and English plans, and by Herr HUBER, relative to the cost when storage batteries are employed, tend to show that for short lines, such as we have just been referring to, electricity will favourably compare with steam power. By utilising the former for illumination as well it would be cheaper than steam, and the cost of maintenance considerably lower. That this has been proved to the satisfaction of American financiers is evident from the fact that the striking success of the lines which have begun working during the past twelve or eighteen months has resulted in the commencement of a great number of additional lines. Nearly a score of these are actually in process of construction; and companies have already been formed for similar undertakings at about forty other places in different parts of the States. Herr HUBER is satisfied that even storage batteries are much cheaper than horse-power for tramway lines; but the facts just cited are conclusive evidence that in America certainly electricity is held to be cheaper than either horse or steam power, at all events on lines for the working of which electricity is peculiarly adapted.

CORRESPONDENCE.

PROF. FORBES'S MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I ask why this dynamo is so persistently called non or uni-polar? It has two poles as much as any other machine, and, with all respect to Prof. Forbes, it would be more correct, and shorter, to call it simply "Forbes's dynamo." The notable feature of this machine lies in the fact that it produces current by aid of a symmetrical field, and not by any special polar properties. Mr. Scattergood, in his letter of the 2nd inst., says, "The rotation of a cylindrical bar magnet about its axis does not induce a current in a fixed metallic circuit placed in its field, because the number of lines of force which pass through the circuit are unaltered by the rotation of the magnet, the field being symmetrical about the axis;" whereas Mr. Voice, in a following letter, shows that a machine can be made to produce current under such conditions.

Mr. Scattergood, in the quotation given above, has negatively stated the law of induction as commonly understood, and I think it is here that the difficulty has risen, inasmuch as this law is not sufficiently definite. In view of the facts before us it would seem that to produce current it is not absolutely necessary that the conductor at any section should traverse or be traversed by a varying field, and moreover that current can be generated if any two or more consecutive sections be passed through such portions of the field as shall have relative inductive properties, although each section may in itself traverse a uniform field. Under such conditions a difference of potential would be established at two points along the path of the conductor with a resulting current.

On reference to the machine illustrated by Mr. Voice it will be seen that the fact of the wires leading to the galvanometer being cut by the lines of force would not account for the current, as an equal and opposing E.M.F. would be set up in each; but when we consider that the collector at the centre (although traversed by a symmetrical field) is under greater inductive influence than that at the end, it is easy to divine the cause of the current. I am afraid I do not agree with Mr. Voice's theory that a magnetic field would not revolve with the magnet. It is undoubtedly true that in an ordinary dynamo current is produced by the reaction of a condition that itself is instrumental in maintaining; but I do not think he has sufficient grounds for establishing a law contrary to all analogy, and I am of opinion that the field and the conductor transmitting the current, or the magnet and its field, are as intimately connected with each other as the atmosphere and earth of our terrestrial system, and would with as much reason revolve together.—Yours, &c., N. G. THOMPSON.

4, Queen Victoria-street, July 14th, 1887.

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have noted with some interest the correspondence lately published in your columns on the above subject. There can be little doubt that many estimates from time to time tendered for electric lighting work mention such a low price that it is impossible the work can be creditably carried out for that sum without loss to the contractors. Now the question of loss or otherwise is a matter for the contractor himself to decide, providing he always carries out his work well whatever it may cost him; but it is particularly to be noted that those who habitually underestimate are those who are least able to bear the loss involved, and therefore their work is badly done. Now, Sir, though we can afford to look on at a firm of contractors making a loss and yet doing their work well, we cannot permit them to do their work badly and continue to produce the bad impression about electric lighting that unfortunately does exist on this account. It is difficult to see how the case can be well met, for even if the trade could manage to arrange a minimum price for each different class of work, those who do their work badly would probably continue to do so and make a large profit.

Probably, therefore, the consulting engineer is the only one who can achieve a radical change, and there is little doubt he would be largely employed if he would consent to accept a moderate fee for small works. Perhaps some of these gentlemen will give us their views on the subject.

If a consulting engineer were always employed the "cheap work gentlemen" would rapidly disappear from off the face of the earth.—Yours, &c., MANVILLE AND MADGEN,

Managing Directors United Electrical Engineering Company.

36, Albert Embankment, London, S.E, July 13, 1887.

THE ZIPERNOWSKI-DERI TRANSFORMERS AT ANTWERP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read with much interest in your issue of the 1st inst. the report of your Brussels correspondent relating to the experiments in electric lighting with transformers carried out by the Société Industrielle d'Electricité of Brussels, and we only beg to add that the dynamos and transformers for that installation have been supplied by our company, the Société Industrielle having bought them from us with the right of using them in combination with the Zipernowsky-Déri system of distributing electricity.—Yours, &c.,

Buda-Pesth, 7th July, 1887. GANZ AND CO.

A SUGGESTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Though there is probably some mistake in the daily journal account of the electric launch to which you refer in this week's "Notes," I have often thought that sailing vessels might be provided with some sort of turbine, which could be used to store electricity in a good wind, so as to drive the vessel by means of an auxiliary screw in a calm.

I should be glad if you could find space for this idea in your pages.—Yours, &c., E. CHURCHILL.

Northwich, July 9, 1887.

THE JUBILEE BEACON LIGHTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The brilliant white glare seen from the Titterstone Clee Hills, Shropshire, with reference to which you have a note

Digitized by Google

in the current number of your journal, doubtless came from three arc lamps which were erected on the top of the church tower (St. Leonard's), Bridgnorth, on the Jubilee night. A pole about 20ft. high was erected on the top of the tower—which stands on the highest point of the hill on which the town is built—and the lamps suspended from three short brackets in the form of a triangle. They were about 3,000 candle-power each, and were Phillips and Harrison's patent, manufactured by Elwell Parker, of Wolverhampton, who also supplied the dynamo, an 8-unit nominal, running under speed. The engine was a Marshall portable, in not very good condition, and required considerable coaxing to induce it to run steadily and not jump about the yard. A very satisfactory run was, however, secured.

On the following Tuesday, Wednesday, and Thursday Bridgnorth held its own Jubilee celebrations, and the lamps, with two additional ones, were erected in the High-street. The lighting was carried out by Councillor Whitefoot and Mr. C. J. Turnbull, of High-street, Bridgnorth, under my supervision. Bridgnorth lies about north-west by north of Titterstone Clee Hills,—Yours, &c., W. B. SAYERS.

Edgbaston, Birmingham.

By a later post we have received the following additional note from Mr. Sayers:—

"On referring to the map I see I am in error in supposing that Titterstone Clee Hills lie about south-east by south of Bridgnorth; they lie about south-west by south, so that Bridgnorth is north-east by north of Titterstone Clee Hills. Nevertheless, I am confident that the Bridgnorth lights or their whereabouts, if something intervenes, must have been easily discernible from Titterstone Clee Hills, and think it probable that a mistake was made as to the direction in which the glare appeared."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I cannot lay claim to the origin of the interesting arc light which was visible on Jubilee night in the direction explained in this day's *Electrician*; but on the night in question I had a Crompton lamp on the top of my house, which stands high on Cannock Chase. The current was supplied from "E.P.S. accumulators," which I have used for house lighting for about 18 months, with perfect success.—Yours, &c.,

F. D. BUMSTED.

Hednesford, Staffs., 8th July, 1887.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 8th you had a note asking where a certain light proceeded from. Messrs. Storey Bros., Lancaster, had a large search light on the top of a high chimney on the night of Jubilee and three following nights. You do not say whether the light seen was a fixed or revolving one. Ours was not directed to any one place for more than 30 minutes [? seconds] at a time. Do you think it possible that it could have been seen at so great a distance?—Yours, &c., J. PARKINSON.

White Cross Mills, Lancaster, July 12, 1887.

[Lancaster is about 140 miles from the Clee Hill, and is also several points round to the north of the direction in which the light was seen, so it is scarcely probable that this is the light in question.—ED. *E.*]

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XLIII.

BY OLIVER HEAVISIDE.

Reflection due to any terminal resistance, and establishment of the steady state. Insulation. Reservational remarks. Effect of varying the Inductance. Maximum Current.

If there be a resistance R_1 at the end B of a non-distortional circuit, its presence imposes the condition $V = R_1C$ at B permanently. If, then, there be a wave travelling towards B, we find the nature of the reflected wave from B by applying the above terminal condition to the actual V and C which are the sum of V_1, V_2 the potential-differences in corresponding portions of the incident and reflected waves, and of C_1, C_2 the currents in these portions. Thus we have

$$V_1 = Lv C_1;\ V_2 = -Lv C_2;\ V_1 + V_2 = V;\ C_1 + C_2 = C;\ V = R_1 C;$$

to represent the full connections. From these we find

$$V_2/V_1 = (R_1 - Lv)(R_1 + Lv)^{-1} = \rho_1 \text{ say}, \quad . \quad (26d)$$

giving the reflected in terms of the incident wave. This ratio is positive if R_1 be greater and negative if it be less than the critical Lv. In the former case there is reversal of current, in the latter of electrification, produced by the reflection. The three most striking cases are when $R_1 = 0$, ∞, or Lv, *i.e.* short-circuit, insulation, and the critical resistance of complete absorption, making $\rho_1 = -1, +1$, or zero. There is partial absorption and loss of energy whenever R_1 is finite, but none whatever in the two extreme cases. The loss of energy is accounted for by the Joule heat in the terminal resistance.

In a similar manner, if there be a resistance R_0 at the near end A, the transforming factor is

$$\rho_0 = (R_0 - Lv)(R_0 + Lv)^{-1} \quad . \quad . \quad . \quad (27d)$$

If there be given an isolated charge moving towards B at a certain time, it will, after reflection at B, be replaced by another charge moving towards A, which may be of the same or of the opposite kind, according as the reflecting resistance is greater or less than the critical. On arrival at A it is transformed into a third charge moving towards B, and so on. There is the usual attenuation ρ in each journey, where $\rho = \epsilon^{-Rl/Lv}$. If there be complete insulation at both ends, there is no other attenuation than this due to the circuit; and similarly, if the ends be short-circuited; but in all other cases it has to be remembered that the act of reflection attenuates, besides causing a reversal of either the electrification or the current.

The complete history of the establishment of the steady state due to a steady impressed force at A is now expressible in terms of the three constants ρ_0, ρ, and ρ_1; with, of course, x the distance, t the time, and e the impressed force. There is first the positive wave

$$V_1 = \tfrac{1}{2}e(1 - \rho_0)\epsilon^{-Rx/Lv}, \quad . \quad . \quad . \quad . \quad (28d)$$

due, as mentioned in the last section, to the union of the initial positive wave of half strength and of the positive wave which is the reflection of the initial negative wave of half strength, which latter is rendered visible by shifting the seat of e towards B. The solution (28*d*) applies to all values of x less than vt, which is the extreme distance reached by the wave at time t after starting. On arrival at B we have to introduce the transforming factor ρ_1 above defined. The reflected wave is therefore

$$V_2 = \tfrac{1}{2}e(1 - \rho_0)\rho^2\rho_1 \cdot \epsilon^{Rx/Lv}, \quad . \quad . \quad . \quad (29d)$$

which is to be superimposed on the former wave to obtain the real state during the second journey, from B to A. The region over which V_2 extends grows at a uniform rate with the time, from B to A. On arrival of V_2 at A we must introduce the transforming factor ρ_0 to obtain the third wave, which is

$$V_3 = \tfrac{1}{2}e(1 - \rho_0)\rho^2\rho_1\rho_0 \cdot \epsilon^{-Rx/Lv}; \quad . \quad . \quad . \quad (30d)$$

this reaches B at time $t = 3l/v$, when the fourth wave commences, which is to be found by introducing the transforming factor ρ_1; thus

$$V_4 = \tfrac{1}{2}e(1 - \rho_0)\rho^4\rho_1^2\rho_0 \cdot \epsilon^{Rx/Lv}. \quad . \quad . \quad . \quad (31d)$$

It is unnecessary to proceed further, as it would only produce repetitions. The positive waves V_1, V_3, &c., have the common ratio $\rho^2\rho_1\rho_0$, and are otherwise similar. Their sum is therefore

$$\tfrac{1}{2}e(1 - \rho_0)(1 - \rho^2\rho_1\rho_0)^{-1} \cdot \epsilon^{-Rx/Lv}. \quad . \quad . \quad (32d)$$

Similarly the sum of the negative waves is

$$\tfrac{1}{2}e(1 - \rho_0)\rho^2\rho_1(1 - \rho^2\rho_1\rho_0) \cdot \epsilon^{Rx/Lv}. \quad . \quad . \quad (33d)$$

The final state of V is therefore expressed by the sum of (32*d*) and (33*d*). In all the positive waves the current is from A to B, and in the negative from B to A; hence the

Digitized by Google

excess of (32d) over (33d) divided by Lv expresses the final state of current.

The solution of the above problem by means of Fourier series is extremely difficult. It expresses the whole history of the variable period by a single formula. But this exceedingly remarkable property of comprehensiveness, which is also possessed by an indefinite number of other kinds of series, has its disadvantages. The analysis of the formula into its finite representatives, so that during one period of time it shall represent (28d), then in another period represent the sum of (28d) and (29d), and so on, *ad. inf.*, is trying work. (I gave it up as a case of "sour grapes.") And the getting of the formula itself is not child's play. Considering this, and also the fact that a large number of other cases besides the above can be fully solved by common algebra (with a little common sense added), the importance of a full study of the non-distortional system will I think be readily admitted by all who are dissatisfied with the views so forcibly enunciated by the eminent scienticulist on the subject of the speed of the current at the time of the last explosion. The important thing is to let in the daylight on a subject which it was difficult to believe could ever be freed from mathematical complications. And on the admission of daylight, the ghosts in the cupboard under the stairs vanish.

There is a rather important remark to be made concerning the two extremes, $R_1 = 0$ and $R_1 = \infty$, at the end of the line, in the above solution. Although described as shortcircuiting and insulation, they do not really represent the state of things existent when we actually terminate a long circuit of two parallel wires by a thick crosswire (the shortcircuit) or leave the ends disconnected in the air. Every theory that ever was made is more or less a paper theory; we must simplify the real conditions to make a theory workable. Now a theory may very closely represent reality (when pursued into numerical detail) through a wide range, and yet go quite wrong at extremes. The justification for making the constants of the circuit independent of its length is that the length is an enormous multiple of the distance between the wires. But if we terminate the circuit somewhere it is no longer true that the permittance and the inductance per unit length are constants, near and at the termination. The theory, to be correct, must wholly change its nature, as may be seen at once on thinking of the changed nature of the electromagnetic field as the termination is reached. Now our theory says that when the circuit is insulated at B, every charge arriving there is at once sent back again unchanged; and that during the period of reflection, the potential difference is doubled and the current annulled. The doubling of the potential difference is obviously due to there being a double charge with the same assumed permittance. But the permittance is not the same, nor anything like the same, at the termination as it is far away from it. The theory therefore wholly fails to represent the case of insulation, so far as the potential difference at the termination is concerned, though there does not seem to be any reason to suppose that this will affect matters elsewhere; for when the reflected wave gets away from the termination, the old state of things is restored. There is a similar want of correspondence between the theory and reality when we make a real shortcircuit, which we have supposed to be represented by $R_1 = 0$.

Now the question may suggest itself: Since this failure is due to the assumption that the permittance and inductance continue constants right up to the termination, and this assumption being made in all cases, may there not also be a failure when R_1 is finite? The following reasoning will show that this is not to be expected. For if the terminal resistance (although it may be small) yet be equal to that of a considerable length of the circuit, the influence of this resistance on the course of events must be much greater than that due to the changed nature of the circuit near its end. We therefore swamp the terminal corrections, which become so important themselves when the terminal resistance is quite negligible.

The general principle that may be recognised is this. If the transfer of energy between the circuit and the terminal apparatus (of any kind) be of sensible amount, we may wholly disregard the fact that the circuit changes its nature as the termination is approached. But should it be insensible, then we fail to represent matters correctly at and near the termination.

Again, if the ends of the circuit, supposed insulated, be brought sufficiently close together, there may be a spark or disruptive discharge there when a charge arrives, involving a loss of energy and attenuation. It is scarcely necessary to remark that effects of this kind have no place in the theory.

In the same connection it may be remarked that when we are following the history of an isolated charge, which may, in the theory, be confined to the shortest piece of the circuit imaginable, we should really spread it over a length which is several times as big as the distance between the two wires. This is to make the element of length have the same properties as a great length. Similar assumptions are made (though seldom if ever mentioned) in most theories in mathematical physics. An element of volume, for instance, must be large enough to contain such an immense number of molecules as to impart to it the properties of the mass.

Returning now to the study of the properties of the circuit, let us examine the effect of varying the constants. For simplicity, insert the critical resistance at B, and let there be none at A, where the impressed force is. The current at B is then

$$C_B = (e/Lv)\epsilon^{-Rl/Lv} = (e/Rl)y\epsilon^{-y}, \quad . \quad . \quad (34d)$$

if $y = Rl/Lv$. The value of e to be taken in the formula at a given moment should be that at A at the time l/v earlier. Now, with the resistance of the circuit kept constant, vary y to make the current a maximum. We require $y = 1$, or the critical resistance should equal the resistance of the circuit (without leakage). It then also equals the insulation resistance $(Kl)^{-1}$. If the resistance at A be any constant multiple of Lv, we shall have the same property $y = 1$ to get maximum current. [But should the resistance at A be kept constant, we shall have $y^2(R_0/Rl) + y = 1$, which it is unnecessary to discuss.] The received current is therefore

$$C_B = e(2{\cdot}718Rl)^{-1}, \quad . \quad . \quad . \quad . \quad (35d)$$

when no resistance at A; and if there be resistance there of amount zLv, we must divide the right side of (35d) by $(1 + z)$ to obtain the current at B. Thus the result is the same as if the circuit were a mere resistance whose value is a small multiple of the true resistance, with abolition of the leakage, permittance and inductance, but with a retardation of amount l/v. This is not the electrostatic retardation, of course; it merely means the interval of time that elapses between sending and receiving, whereas electrostatic retardation, as formerly understood, is quite another thing. Neither is it the speed of the current; that is v. But singularly enough, the value of the electrostatic time-constant RSl^2 is now l/v itself, proportional to the first power of the length, and inversely proportional to the speed of the current.

Example.—1,200 kilometres at 2 ohms per kilom. Lv should be 2,400. If it be an air circuit, of copper, with v practically = 30 ohms (the formulæ for permittance, inductance, &c., will be given later), we require $L = 80$. This is much too great. The inductance must be artificially increased, if we are to have so little attenuation as above on a circuit of that length. Or the resistance may be reduced. If 1 ohm per kilom., $L = 40$ is wanted. If $\frac{1}{2}$ ohm per kilom., $L = 20$.

The shorter the circuit the smaller is the value of L needed to get the maximum current, and the longer the circuit the greater L should be. If L could be made large enough, without altering the resistance, the circuit could be of any length we pleased. The lower the resistance of the circuit, the less leakage is needed to prevent distortion, and the less attenuation there is. The higher the resistance, the more leakage is needed, and the greater is the attenuation. We see by inspection of (34d) that without varying either the resistance or the permittance, but solely by increasing L (remembering that $Lv = (L/S)^{\frac{1}{2}}$), we could make Atlantic fast-speed telegraphy possible, with little attenuation and distortion. But the speed of the current would be very low. This I shall return to in connection with the sinusoidal solution.

(To be continued.)

WHAT IS ELECTRICITY?*

BY TOWNSEND WOLCOTT.

It is a common statement that energy can neither be created nor annihilated, and that the total energy in the universe is a determinate quantity. The first part of this statement, although true, is not in itself of vital importance, while the latter part is not true. It is perfectly true that neither time nor space can be created nor annihilated, and yet nobody attaches special importance to this fact, or says anything about the conservation of time or space, and certainly nobody ever tried to prove as a corollary that the total amount of time or space in the universe is a determinate quantity.

The true value of this principle of the conservation of energy is, that it is the expression of the quantitative relations of phenomena. Nearly all, if not all, phenomena consisting of change, or succession of events in time, are referred to force; now we find that all measurable forces have a definite quantitative relation to each other (the correlation of forces), such that the disappearance of one kind of activity, change of position, &c., of material bodies cannot take place without the appearance of an equivalent amount of some other form or forms of activity, &c. This it is that makes the conservation of energy the keystone of modern science. It is the modern equivalent for the old cause and effect.

Potential energy may always be expressed as the line integral of a force. When the force follows the law of inverse squares, as in gravity, electric and magnetic attraction, the integral is finite even when the upper limit of integration is infinite, providing the lower limit is finite; but if the lower limit is zero the integral is always infinite, and therefore the potential energy (in case of attraction but not of repulsion) of a finite system is infinite. If we have a system of attracting bodies, say, gravitating masses, this infinite value will represent what may be called the total potential energy of the system, but the bodies having come into actual contact, if we suppose them incompressible, have parted with all their available potential energy, the other part corresponding to the dissipated energy in the theory of heat.

Now, this available energy where the bodies vary in size, shape, density, &c., is different for every final arrangement, as the closeness of final contact would depend on this; also the arrangement which brought the denser bodies nearer the common centre of gravity would, other things being equal, give the greater value to this available energy. As the order of approach of the bodies may be changed without altering the amount of energy, we must conclude that the latter is either infinite or indeterminate, according to which measure of energy we adopt. Maxwell states that "the existence of a potential function in the field near an electric current is not a self-evident result of the principle of the conservation of energy," as the potential has an infinite number of values differing by $4\pi i$, so that an infinite amount of work may be done on a magnetic pole which is carried round the conductor an indefinite number of times. The work, however, is always a determinate quantity when the limits of integration are finite, as in the previous case. I consider the cases somewhat analogous. The kinetic energy of a moving mass is $\frac{mv^2}{2}$, and we sometimes see it stated that this energy resides in the body. But as the velocity of a body is merely relative, this kinetic energy will have a different value for every other moving body with which we compare the given one.

If two bodies collide, they will, in coming to a common velocity, convert all their available energy (available relative to each other) into some other form, and if we regard some third body as a standard of reference, there will still be a quantity of energy dissipated, the amount, of course, being different for each different body taken as a standard. The reason why the idea of the dissipation of energy has assumed such importance in the theory of heat is that the energy of a hot body is referred to a so called absolute zero of temperature; but this being below the temperature of interstellar space, so far as we know it, we can no more reach it experimentally than we can the absolute zero of contraction mentioned above.

Prof. Dolbear, in his reply to Mr. Carl Hering on this subject, speaks of energy as an objective condition. Here is just where I would differ with him.

Energy is certainly an abstract concept, a class-designation for a variety of forms, and we in these times believe in the philosophy of Aristotle rather than that of Plato. Or to come down to later times, Kant considers time and space as subjective impressions, and it is in this category that I would place energy also, from its interchangeability with the others as a fundamental unit. To assist us in completely freeing our minds from absolute notions, let us consider a remark made by De Morgan, in an article on the "Calculus of Functions," namely, that we are accustomed to regard quantity as being generated by the successive additions of *equal* increments; thus an hour is considered as the sum of sixty equal parts called minutes, a minute of 60 seconds, and a second may be considered as composed of an indefinite number of smaller equal parts. This is the most natural process for the human mind, but conceive of a mind to which the natural process would be to consider quantity as generated by the successive addition of *percentage* increments; to such a mind what to us is the theory of logarithms would be the common arithmetic, and what we express as $a + b$ would be a difficult operation. In fact, it was by employing this conception of kind that Napier discovered logarithms and not by the extended conception of exponents, as is sometimes supposed. I have given De Morgan's meaning from memory and do not quote his words.

Let us apply a similar method of analysis to the theory of fundamental units. Maxwell gives length, time, and mass as the three fundamental units on which all others are made to depend. These units, however, are fundamental only in a relative sense, as we may take other magnitudes as fundamental, and make length, time, and mass depend on these.

The most general statement of the theory is that three independent units having been established; all other physical units may be made to depend on these, reducing the whole to a connected system.

Space, or the more specialised conception, length and time, are among the earliest abstract notions acquired by the human mind, but with mass the case is different. It is only since the general adoption of the principle of the conservation of energy that the conception of mass has attained its present distinct individuality, it being in fact a more refined substitute for the "weight" of the older science. The *vis viva* of Newton (which was equal to twice the kinetic energy) was not mv^2 but $\frac{wv^2}{g}$, w being the weight and g the force of gravity. Energy, then, has at least an equal title with mass to the position of fundamental unit, on the ground of being in the natural order of our mental processes. We may therefore substitute energy for mass, and using E as its symbol and Maxwell's notation, we have the dimensions of the unit of mass $[E\,T^2\,L^{-2}]$; and in fact the only definition of mass we have which is at all characteristic contains this formula by implication.

We may define mass as that which possesses weight or attraction for other masses; but it is only when we add that a mass moving with a given velocity is capable of doing a definite amount of work that we obtain any distinctive idea of mass. Instead, however, of substituting energy for mass we might substitute it for either length or time, and conceive of a mind, according to De Morgan's method, to which this would be the natural order.

Again, we always think of a velocity as the ratio of a distance to a time, but there is no reason why we should not regard velocity as an independent magnitude, and a time the ratio of distance to velocity; or a distance, as the product of a velocity and a time, according to which substitution is made. Now, according to a statement of Prof. Dolbear, that energy has an objective existence as well as matter, of which the measure is usually considered mass, and ether, which as yet has no measure, we may construct a system of fundamental units of which one or two are the measures of objective realities, while the remaining two, or one, are merely subjec-

tive impressions. If the ether had an independent measure we might take mass, energy and ether as fundamental units, making all three objective, or, adopting the vortex theory, and discarding mass, we must take in again one of the merely subjective magnitudes to fill its place. This proposition, to my mind, is a good deal like saying that one of the dimensions of space has an objective existence while the others have not. Preceding the discovery of the conservation of energy was the discovery of the indestructibility of matter, and in some of the older works on chemistry it is stated that, while all other attributes of matter are changeable, the absolute weight remains unchanged under all conditions.

As the weight is only determinate under determinate conditions, it has been recommended that conservation of mass should be substituted for indestructibility of matter, mass being considered the only thing which remained unchanged. But is this correct?

All the chemical properties of a body have determinate magnitudes when a sufficient number of conditions are fixed, and the whole method of volumetric chemical analysis is founded on this principle.

I have gone thus at length into the general theory of conservation to show that it does not necessarily apply alone to energy and mass, but that the abstract generalization from any complete series of quantitative relations between measurable magnitudes, not included in these two, is a new conservative principle.

For if it were not a conservative principle then the magnitudes would not always have the same quantitative relations. Conservation is the statement of the uniformity of nature, or, if you prefer the expression, the constancy of natural law. I will add that the conservation of energy is so broad a principle that nothing outside of it is likely to be of very great importance. From this point of view it is no more than we should expect that some one should establish a conservation of electricity, as Prof. Sylvanus P. Thompson seems to have done, nor is it any proof that electricity is matter, as Mr. Carl Hering appears to think. The most direct proof to my mind that electricity is not matter, is the experiment of Maxwell, tried in 1861, to prove that the electric current has no momentum.

The answer to our question depends in a great measure on the definition of electricity. The electrostatic unit of quantity is identical with the unit of electrification, and the electrification of an insulated conductor in equilibrium is all upon the surface; that is, where the conductor ends and the new conductor begins. This quantity of electricity is as definite a physical quantity as any other, as the operations of measurement, addition and subtraction may be *experimentally* performed upon it, which is all that we can do with any physical quantity. We may therefore regard electricity as existing in two dimensions (which, by the way, matter has never been known to do). Still, whether we adopt the theory of action in a distance, or Faraday's theory, mathematically developed by Maxwell, of stress in the dielectric, we cannot ignore the fact that there is a definite distribution of force in the surrounding space, which is investigated in the theory of potential. Let us take the analogy of a shadow. A shadow in ordinary language is a darkened *surface*, but this darkened surface is merely a section of a darkened *region*, and it is this darkened region that is called the shadow in astronomy. The superficial shadow cannot exist without the solid shadow, and, on the other hand, the solid shadow cannot exist without there being a superficial shadow on a properly placed surface. Of course, to us a shadow is a mere negative, the absence of light. But suppose some one to be investigating it, not knowing that it was only a shadow, he might regard the superficial phenomenon as the direct action at a distance of the opaque body, or he might assume an ether with all sorts of convenient properties, and explain matters in that way. But we regard the superficial and solid shadows as merely different phases of the same phenomenon.

The trouble with our question as usually put is, that we define electricity as we have just done, then insist that this is the genuine article, and fundamental in its nature, while all other phenomena which are essentially electrical are merely consequences of this fundamental quantity of electricity, and then we demand, What is electricity? That is to say, which of three or four other things that we allow to have a real existence, viz., matter, energy, &c., is it? I would answer emphatically it is no one of them.

Let us abandon absolute ideas and treat all electrical phenomena as equally fundamental, simply striving to discover their relations to each other, and to other phenomena; then each discovery is a partial answer, and the only kind of an answer we will ever have to our question. As to our present knowledge of the subject, it is as great as of any other subject in natural science. Indeed, Maxwell says in his preface:—"The internal relations of the different branches of the science which we have to study are more numerous and complex than those of any other science hitherto developed."

I have often put the counter-question to my friends, What is heat? The unscientific ones usually say, "Heat? Why anybody knows what heat is; there is no use of such a question!" Or, "Heat is heat;" or, "Heat is the opposite of cold." Those that have read Tyndall reply very glibly that heat is a mode of motion. But Tyndall's book only proves, and indeed only sets out to prove, that heat is a form of energy. We know that electricity, as we define it, is not energy; but we do know what its relation to energy is, which is just as important and characteristic knowledge as we have in the case of heat.

THE UNION ELECTRICAL POWER AND LIGHT COMPANY.

On Wednesday afternoon, at Palace-chambers, Westminster, Prof. George Forbes, F.R.S., delivered an address upon the storage battery to a number of gentlemen, who attended upon the invitation of the Union Company. After a few introductory remarks from the chairman of the company, Prof. Forbes delivered an interesting address, of which the following is an abstract:—All present would remember how great were the expectations which were aroused some few years ago on the advent of the Faure storage cell, and how comparatively meagre was the success which that battery actually attained in practice. He would endeavour to lay before them point by point the causes of the failure of the original Faure cell, indicating at the same time the manner in which these defects had been obviated in the battery of the Union Company. (1) In the first place the mechanical construction of the Faure cell was such as to utterly unfit it for much of the work which secondary batteries were called on to perform. The negative plates consisted of a sheet of lead, against which was laid a paste of the salts of lead, and this paste was retained in position by an envelope of felt. This arrangement was obviously weak, and in practice, after a little time, the slightest jolting caused the paste to peel off from the lead surface, and before long the acid destroyed the felt covering. In the Union cell the negative plates consisted of an absolutely solid mass of lead peroxide, which had no tendency whatever to disintegrate under the action of the acid, and would bear plenty of rough usage. This form of peroxide was the invention of Mr. FitzGerald, and had received the name of lithanode.

(2) In a battery used for locomotive purposes the question of weight was of great importance. In the Faure cell, as already explained, the negative plates were necessarily made with heavy masses of lead to support the litharge. In the Union cell the negative plate consisted solely of the active material, and no lead backing was required, thus effecting a very great saving in weight. He (Prof. Forbes) had at various times tested over a dozen cells of different types, of which there were only one or two on which he had been able to give a favourable report; but of all these the Union cell was by far the best in respect of capacity of discharge for a given weight of material.

(3) The third point in favour of this cell was one of high value, though he did not pretend fully to understand the reason for its existence. It was this. In lithanode cells there was no tendency to the formation of white sulphate. In all other lead batteries with which he was acquainted—even in the cells at present made by the Electrical Power Storage Company, which he would say were excellent cells in many respects—there was an unfortunate tendency to the formation of a salt of lead whose presence prevented the full utilisation of the capacity of the cell. The only method by which the formation of the sulphate can be prevented, and the only conditions under which cells of the E. P. S. type can be worked with full success, is that they are regularly and constantly charged to their fullest capacity. If these cells are allowed to remain at

Digitized by Google

rest, after being even partially discharged, sulphating sets in. When the sulphate has once been formed in any quantity, the way of getting rid of it is to charge the cell continuously for a lengthened period of time until all traces of sulphate have disappeared. This, of course, is an expensive process, although it is perfectly effective. The Electrical Power Storage Company consequently recommend their customers never to allow their cells to remain discharged for any length of time. This is, to say the least, a little awkward, if, for instance, an installation in a town or country house is intended to be disused for any portion of the year. As he had already stated, this drawback was entirely absent in the case of the Union cell.

(5) The next point he would refer to was the indestructible character of the electrode or contact plate, consisting of a thin strip of platinum enclosed by celluloid. It was true that the use of this material added somewhat to the first cost of the cell, but the platinum being absolutely unalterable, this part of the outlay was of the character of capital expenditure.

(6) The Union cell might be completely discharged and left in this condition for any length of time without, so far as he had yet been able to discover, any deterioration whatever. He had repeatedly taken partially discharged plates, laid them aside for weeks at a time, and then found them as good as ever. This was a very severe test indeed.

He would proceed to note a few of the minor advantages of the cell. Lithanode plates were admirably adapted for use in primary batteries. At present, for ordinary domestic and telegraphic use, there was no cell so extensively employed as the Leclanché, which in its own field had long remained practically without a rival. He thought, however, that the Leclanché would now have difficulty in maintaining its supremacy as a single-fluid cell against the use of lithanode. A plate of carbon sandwiched between two pieces of lithanode and opposed by a plate of zinc formed in his opinion the best depolarising single-fluid cell yet invented.

In charging a secondary cell there usually occurred towards the end of the process a rise of the back E.M.F. from 2 volts to 2·25, or 2·5 volts. This not only entailed a waste of power, but was also attended by practical inconvenience. In the lithanode cells the spurious E.M.F. did not make its appearance, or only very feebly, which was again a feature of no small value.

Coming to some numerical details, he might state that the capacity of the cell amounted to 39·16 watt hours per kilogramme of active material, or 18 watt hours per lb. of active material, or, again, 31·5 kilogrammes per horse-power hour, including the casing of the cell.

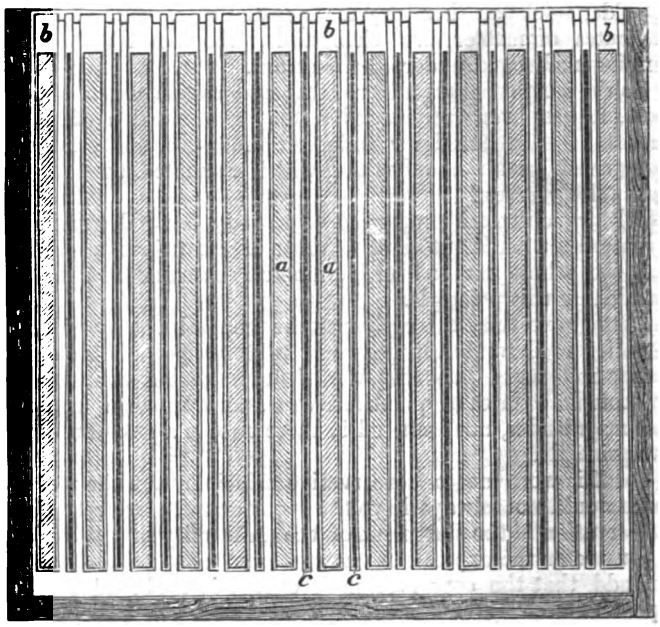
As to the important question of duration, it was impossible as yet to assign any limit to the life of the cells, sufficient time not having yet elapsed. He must therefore confine himself to the statement that cells which had been in use for two years showed no signs of deterioration, but were in all respects as perfect in condition as those of recent manufacture.

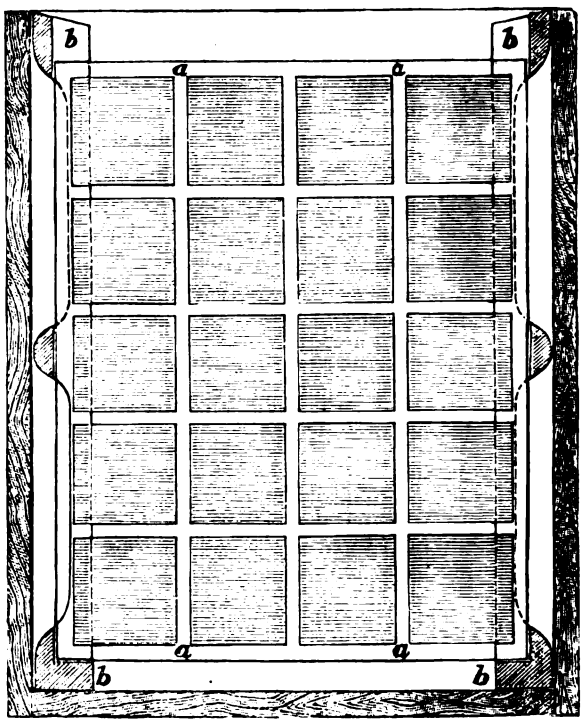
Mr. Henry Lea, of Birmingham, then related some results of his experience with secondary batteries, which he had employed for lighting his own house. With E.P.S. cells he found that, for the reasons which Prof. Forbes had explained, it took upon the whole twice as much engine-running per annum to maintain the installations in proper order as with the cells of the Union Company, which he had now in use. He had subjected these cells to very rigorous treatment, twenty-two times in succession he had half-charged them, and then discharged them as completely as possible. This would, in his experience, have ruined any other cell; but the lithanode plates came out of the trial apparently unharmed, and on testing their capacity he found it quite unaltered. In daily use charging and discharging went on with such perfectly uniform results that he now found it unnecessary to keep any watch upon the cells themselves; a glance at the voltmeter told him when they were fully charged, and the action went forward with as much regularity as if the whole process was a purely mechanical movement instead of being based upon a rather subtle chemical reaction.

Several questions were then asked to which Prof. Forbes replied, and batteries of various power were shown at work driving Immisch motors, lighting lamps, &c.

CORNELIUS SMITH'S STORAGE CELLS.

We illustrate herewith a form of secondary battery which has been introduced by Mr. Cornelius Smith, and we also print below an extract from a report upon the cell made by Mr. L. B. Miller, A.S.T.E. From this it will be seen that the only new feature of the cell consists in the use of thin pieces of lead foil, which are packed edgewise in rectangular holes. The lead slips for the negative plates may either be painted with red lead before introduction, or both plates may be made of plain lead and formed as in the Planté battery. The lead slips are packed somewhat tightly in the first instance, and the expansion produced in charging wedges them firmly in, while all tendency to buckle is obviously avoided. This construction is an undeniable improvement over previous cells of the same general type, but we do not feel called upon to express any opinion as to whether or not the construction is sufficiently novel to steer clear of existing patent rights. We may, however,





In these figures *a* is a grating with rectangular openings, which are filled in the manner described with strips of lead. The plates *a*, when so made and filled up, are inserted into grooves formed in guides *b*, made of vulcanite or other suitable non-conducting material. *c c* are perforated sheets of vulcanite or other material, which, placed between each pair of plates, serve to prevent their circuiting by reason of dirt or scaling.

point out that in the Smith cell contact is made with the grid by every separate lead slip, while in the Elieson type, which it most nearly resembles, contact with the grid is obtained only upon the outer surface of each roll of lead tape, and the current taken off has to traverse all the external convolutions of the roll.

Digitized by Google

Some cells of this description have been in use for some time at Whiteley's, in Westbourne-grove, and Mr. Percival, who is in charge of the electrical department there, speaks very highly of their behaviour. We have had also an opportunity of examining some plates which had been in use about three months, and which seemed to be in very good condition, being well formed throughout. Speaking generally, we have been very favourably impressed with the battery, and as against other cells in which a grid is used with the negative plate we are under the impression that this is the best arrangement hitherto devised.

The following is an extract from Mr. Miller's report above referred to :—

The accumulators consisted of 12 cells, with three plates in each, one positive and two negative. The plates consisted of a grid of cast lead about 5½ by 3½, with rectangular spaces an inch square, filled up with thin lead strips placed loosely one on the top of the other. In the cells submitted for testing, which were intended for lighting purposes, the lead strips had been painted with red lead before being packed in, and red lead had also been pressed into the strips from the surface of the plate. The strips made excellent contact with the frame, and although they were packed more tightly than I should consider advisable, on breaking a plate to pieces I could see that the interior surface of the strips was becoming active although the cells were far from being fully "formed." The value of an accumulator depends chiefly on the following points :—

1st. *The efficiency*—*i.e*, the percentage of electricity that can be got out compared with what has been put in.

2nd. *The capacity*—*i e*, the quantity of electricity that can be stored in a cell of a given size and weight.

3rd. *The life* of the cells—*i.e.*, the rate at which they deteriorate with usage.

The Smith and Mensing accumulator comes up to these requirements, in my opinion, to the following extent :—

Efficiency.—The electrical and chemical action in these cells is exactly the same as in others formed of lead plates, and their efficiency is the same, *i.e.*, it ranges between 50—80 per cent. of useful return, depending on the rate of discharge.

Storage Capacity—This depends on the quantity of active material, spongy lead, and lead peroxide there is in the cells. To obtain a large quantity a large surface must be exposed to the action of the current ; but it has been found in practice very difficult to combine this with the necessary amount of mechanical strength in the plates to make them stand ordinary usage in installations. In the accumulators submitted to me this requirement of large surface is very well met, and without in the least weakening the plates. The current is able to penetrate into the spaces between the strips and make the whole of their surface active, the only effect of the resulting expansion being to make the strips fit the space they occupy more tightly and make better contact with the frame. This result is of very great importance as the failure of accumulators is nearly always due to "buckling" and consequent short-circuiting, the buckling being due to the unequal expansion of the two sides of the plate causing it to assume a curved form. I have charged and discharged the new accumulators at about four times the usual rate without them showing the least signs of "buckling."

Life of the Cells—I am convinced the accumulators will give highly satisfactory results in this direction, as two of the worst causes of destruction, "buckling" and falling out of the peroxide, are not likely to occur.

Speaking generally I consider the new accumulator to be a good and sound cell, and one likely to give satisfaction in working.

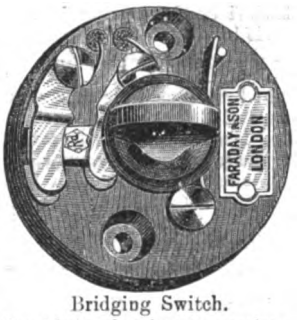
The following details are given as to one particular type of these cells :—

Description of Cells.		Working Rate		Capacity.	External Dimensions.				Weight.
No. of Plates.	Material of Box.	Charge Amps.	Discharge Amps.	Ampere Hours.	Length ins.	Width ins.	Height ins.	Height over all.	Complete with Acid about
13	Vulcanite in Teak or Glass.	30—40	,, to 45	400	9	8	9	10	65lbs.

NEW INCANDESCENT FITTINGS.

A new switch has just been registered and brought out by Messrs. Faraday and Son, of Berners-street, W., designed by Mr. Howard Swan, of which we give a sketch. As will be seen from the illustration, the switch is on a very simple principle. The two double spring contacts, to which the ends of the wire are screwed, are bridged across by a brass connecting piece when the handle is turned. A quick break is obtained by the action of a steel spring bearing upon the end of the connecting piece in the manner of the blade of a pocket knife. The wires come in through two holes at the upper edge, making it easy to wire and fix, and the screw cover allows of easy after inspection. The covers are of boxwood, rosewood, or ebonised wood of neat and ornamental pattern suitable for house lighting.

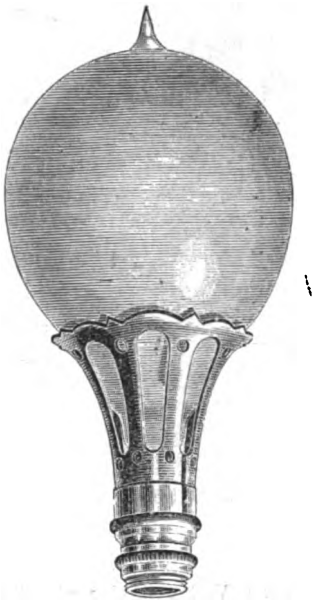
The main point in this switch seems to be that the contact is a pure electrical "bridge-over," *i.e.*, the circuit does not go through any joint of the moving parts where oil or dust might add to the resistance. The double-spring contacts give a good conducting surface, and the switch may be used for 1 to 6 lamps at 100 volts.



Bridging Switch.
Top View, showing connections.

Side View.

The same firm have also recently introduced a new form of lamp-holder of an ornamental pattern which they term the Sydenham holder, and which is certainly a great improvement upon the somewhat amateurish holders which have so long held the market. The graceful lines of the incandescent lamp are here carried on by the outline of the holder, which at the same time serves to cover up the actual joint of the wires.



Faraday's Sydenham Holder.

The holder is made of pierced brass—polished, bronzed, or silvered—passing over a boxwood block, on which are mounted the connecting screws, and the spring contact hooks for the lamp. The lamp can be hooked on at ease to these hooks ; the holder is then pressed up to the neck of the lamp, and the whole tightened up with the backnut, which puts a slight tension on the springs. Messrs. Faraday have just introduced a larger size of these holders, giving greater space (⅜in.) at the point of connection.

THE VORTEX TURBINE.

Messrs. Gilbert Gilkes and Co. have been engaged for many years in the manufacture of the Vortex water wheel or turbine invented by Prof. James Thompson, C.E., F.R.S., &c., and during this time it has been brought into extensive use for a great variety of purposes in all parts of this country and abroad. It has been applied on falls ranging from 3ft. to 400ft. Since the development of electric lighting these turbines have been largely used for this purpose, and are successfully driving various installations on falls of varying heights. The Vortex turbine is made with the outer case and guide blade chamber complete in one piece ;

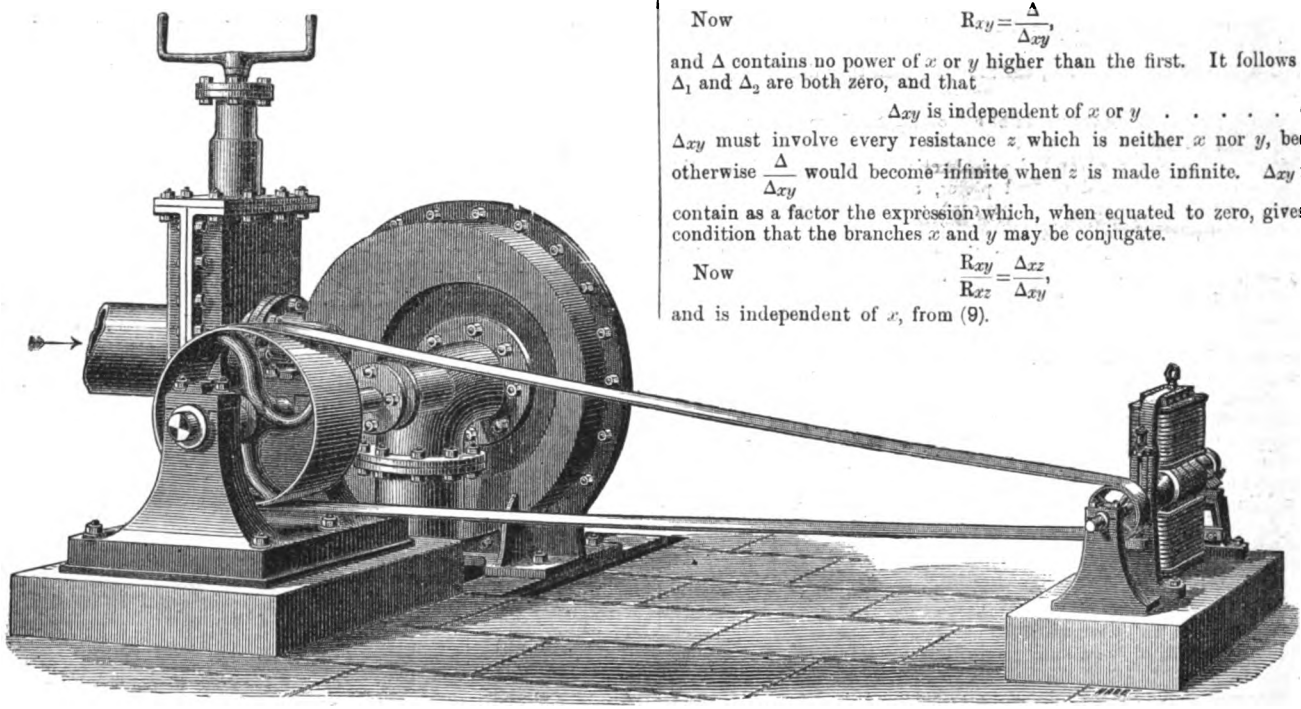
Digitized by Google

the foundation and method of fixing are consequently very simple. By means of movable guide blades the power can be adjusted with great ease to suit varying requirements. The water space being reduced equally around the periphery of the wheel, loss by shocks is avoided, insuring also a uniform speed under varying loads.

This turbine departs from the best known types, such as the Fourneyron or Jonval, in the manner in which the water passes through the guide chamber. It will be borne in mind that in turbines of the Fourneyrou type the water enters at the centre and leaves by the periphery of the wheel, and in the Jonval turbine the flow is in a direction parallel to that of the axis of revolution. In the Vortex turbine the water enters at the circumference of the wheel, and leaves on both sides of the centre by *suction pipes*. These suction pipes are another distinctive feature worthy of note, inasmuch as by their means the turbine can be erected *above* the tail race at any convenient height not exceeding about 25ft.

It is obvious that the elevation is limited to something less than the height of the water barometer. The full height of the fall is also still utilised, for the apparent loss of lead is made good by the action of the suction pipe. And this is done with the same certainty and effect as if the wheel were placed horizontally at the bottom of the fall. The turbine can thus be placed vertically, and so coupled direct to the work without intermediate gear; or, if gearing is necessary, since the power is transmitted with parallel shafts, the loss is less than when mitre gear is used. This peculiarity makes them especially adapted for high-speed machinery, such as dynamos.

Installations have been carried out in this manner at Cragside, the residence of Lord Armstrong, and at Braemore at Sir John Fowler's house.



The Vortex Turbine.

Our illustration shows a Vortex turbine placed vertically above the tail race and coupled to a small dynamo by belting. The delivery and suction pipes are sufficiently clearly indicated without further note. The demand for the utilisation of water-power is continually increasing, and we have no doubt but that Messrs. Gilkes and Co. will have plenty of work for the Vortex turbines in connection with the electrical transmission of power.

THE MEASUREMENT OF SELF-INDUCTION, MUTUAL INDUCTION, AND CAPACITY.

BY W. E. SUMPNER, B.SC.

(Continued from page 190.)

Now if the currents in the $(n+1)$ branches $a\ b\ c\ \ldots\ x$ are such that no one can be deduced from the others whatever the resistances of the remaining $(2n-1)$ branches, the $(n+1)$ branches in which they flow must be each short-circuited by making these resistances zero; otherwise three or more of the branches $a\ b\ c\ \ldots\ x$ will be brought together at a point which is only connected to the rest of the network by the branches so brought together. Under these circumstances one of the currents will be deducible from the remaining n, and this is contrary to supposition.

If, on the other hand, the currents in $(n+1)$ branches $a\ b\ c\ \ldots\ x$ are such that one is deducible from the rest whatever the resistances of the remaining $(2n-1)$ branches of the network, similar reasoning shows that these $(n+1)$ branches cannot be each short-circuited by diminishing the $(2n-1)$ resistances to zero.

The truth of (7) is now established.

Now, by definition,

$$R_{xy}=\frac{\Delta}{\Delta_{yx}},$$

and we may write $\Delta_{yx}=\Delta_{xy}$, since $R_{xy}=R_{yx}$.

Now Δ is of degree $(n+1)$ and Δ_{xy} of degree n. Δ_{xy} cannot contain the square of any resistance; for suppose $\Delta_{xy}=z^2\Delta_1+\Delta_2$, where z is any branch which is neither x nor y. The only effect of making z infinite is to diminish the degree of the network by unity, for two points and three branches are removed. We shall get

$$R'_{xy}=\frac{\Delta'}{\Delta'_{xy}},$$

where, since the degree of the network is now $(n-1)$, Δ' will be of degree n and Δ'_{xy} of degree $(n-1)$. If $\Delta_{xy}=z^2\Delta_1+\Delta_2$, and we make z infinite, the new value of R_{xy} will be zero unless Δ contains a term $z^2\Delta''$. It is physically impossible for R_{xy} to be zero, for finite electromotive forces will then produce infinite currents, and if Δ does contain a term $z^2\Delta''$ the new value of Δ will be of degree $(n-1)$, whereas it must be of degree n. Since x, y, z are any three branches of the network, it follows that

Neither Δ_{xy} nor Δ can contain the square of any resistance in any of its product terms . . . . . (8)

Now, since Δ_{xy} is symmetrical in x and y, it may be written

$$\Delta_{xy}=(x+y)\Delta_1+xy\Delta_2+\Delta_3.$$

But, from physical considerations, R_{xy} must become infinite whenever x or y becomes so.

Now $$R_{xy}=\frac{\Delta}{\Delta_{xy}},$$

and Δ contains no power of x or y higher than the first. It follows that Δ_1 and Δ_2 are both zero, and that

Δ_{xy} is independent of x or y . . . . . (9)

Δ_{xy} must involve every resistance z which is neither x nor y, because otherwise $\frac{\Delta}{\Delta_{xy}}$ would become infinite when z is made infinite. Δ_{xy} must contain as a factor the expression which, when equated to zero, gives the condition that the branches x and y may be conjugate.

Now $$\frac{R_{xy}}{R_{xz}}=\frac{\Delta_{xz}}{\Delta_{xy}},$$

and is independent of x, from (9).

It also follows that $$\frac{R_{xx}}{R_{xy}}=\frac{\Delta_{xy}}{\Delta_{xx}},$$

and is independent of x, since Δ_{xx} does not contain x.

Hence $\frac{R_{xy}}{R_{xz}}$ and $\frac{R_{xy}}{R_{xx}}$ are independent of x . . . . (10)

These properties but express the physical fact that if in a network of conductors there be a source and sink of electricity, and the current entering the one and leaving the other be known, the amount of the current in any branch is perfectly determined, supposing no intrinsic electromotive forces in the network.

Now $$R_{xx}=x+R_{ox}=\frac{\Delta}{\Delta_{xx}};$$

whence $$R_{ox}=\frac{\Delta-x\Delta_{xx}}{\Delta_{xx}} \quad \ldots\ldots\ldots (11)$$

Now $\Delta - x\Delta_{xx}$ is the value of Δ when x is put equal to zero, and Δ_{xx} is the coefficient of x in Δ, and R_{ox} is the resistance of the network between the extremities of x, supposing x removed.

This is an expression for the resistance between any two points of any network whatsoever.

It follows from (5), (6), and (7) that R_{xy} is perfectly determined when the branches x and y meet at a network junction.

We have therefore fully determined

$3n$ network functions of the form R_{xx},
$6n$, , , R_{xy}.

Digitized by Google

The condition of conjugacy can be readily deduced from Maxwell (Vol I., sec. 282A).

Let A and C be the extremities of the branch x of the network.

„ B and D „ „ „ y „

„ $R_{(AD)}$ be the resistance of the network between the points A and D.

„ $R_{(DC)}$ „ „ „ „ D and C.

„ $R_{(CB)}$ „ „ „ „ C and B.

„ $R_{(BA)}$ „ „ „ „ B and A.

Let A B C D denote the potentials of the corresponding points on the network. By supposition the branches x and y are not directly connected. Join the points A D by a wire of resistance z and containing an electromotive force E, and let E be the only electromotive force in the network;

then
$$\frac{A-D}{E}=\frac{R_{(AD)}}{z+R_{(AD)}}.$$

But by Maxwell—Vol. I., sec. 281, equation (10)—we have in this case

$$\frac{A-D}{E}=\frac{2\Delta'_{ad}}{z\Delta'},$$

where Δ' is a determinant of the conductivities of the branches, and Δ'_{ad} one of its minors. It follows

$$\frac{2\Delta'_{ad}}{\Delta'}=\frac{z}{z+R_{(AD)}}R_{(AD)}.$$

z in our case is infinite, so that

$$\frac{2\Delta'_{aa}}{\Delta'}=R_{(AD)};$$

and Maxwell's equation of conjugacy (sec. 282A) becomes

$$R_{(AD)}+R_{(BC}=R_{(AB)}+R_{(CD)}.$$

Now, whenever this is satisfied, Δ_{xy} must vanish. Δ_{xy} must therefore contain as a factor

$$R_{(AD)}+R_{(BC)}-R_{(AB)}-R_{(CD)} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

Maxwell's investigation shows

$$R_{xy}=\frac{2xy}{R_{(AB)}+R_{(DC)}\cdots R_{(AD)}-R_{(BC)}} \quad . \quad . \quad . \quad . \quad (13)$$

$$=\frac{\Delta}{\Delta_{xy}}=\frac{2xy}{R_{(AC,\,BD)}}, \text{ suppose.}$$

Now, if x and y be any two branches, we may write

$$\Delta=x\Delta_1+y\Delta_2+xy\Delta_3+\Delta_4 \quad . \quad . \quad . \quad . \quad (14)$$

where Δ_1, Δ_2, Δ_3, and Δ_4 are independent of x and y; whence

$$R_{(AC,\,BD)}=\frac{2xy\Delta_{xy}}{\Delta}, \text{ and } R'_{(AC,\,BD)}=\frac{2\Delta_{xy}}{\Delta_3},$$

where $R'_{(AC,\,BD)}$ is the value of $R_{(AC,\,BD)}$ when x and y are each infinite; or

$$R_{xy}=\frac{\Delta}{\Delta_{xy}}=\frac{2\Delta}{\Delta_3 R'_{(AC,\,BD)}} \quad . \quad . \quad . \quad . \quad . \quad (15)$$

Δ_3 being the coefficient of xy in Δ.

Now
$$R_{xx}=\frac{\Delta}{\text{coefficient of } x \text{ in } \Delta}$$
$$=\frac{x\Delta_1+y\Delta_2+xy\Delta_3+\Delta_4}{\Delta_1+y\Delta_3}.$$

Change y to y' and let the new value of R_{xx} be R'_{xx}: we easily obtain

$$\frac{1}{R_{xx}}=\frac{1}{R'_{xx}}+(y'-y)\frac{\Delta_1\Delta_2-\Delta_3\Delta_4}{\Delta\Delta_1},$$

where Δ' is the value of Δ when y' is put for y.

But from (19) we obtain

$$\frac{1}{R_{xx}}=\frac{1}{R'_{xx}}+\frac{y'-y}{R_{xy}R'_{xy}},$$

and from (9) we have

$$\Delta_{xy}=\frac{\Delta}{R_{xy}}=\frac{\Delta'}{R'_{xy}};$$

whence

$$\Delta^2_{xy}=\Delta_1\Delta_2-\Delta_3\Delta_4 \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

so that Δ possesses the property that whatever branches x and y be chosen $\Delta_1\Delta_2-\Delta_3\Delta_4$ is a perfect square (see 14), and whenever two branches are conjugate Δ breaks into factors.

$$R_{xy}=\frac{\Delta}{\pm\sqrt{\Delta_1\Delta_2-\Delta_3\Delta_4}} \quad . \quad . \quad . \quad . \quad . \quad (17)$$

This determines R_{xy} in all but the sign. If it is only necessary to determine the integral of the current through one branch of the network, the network functions may be considered positive quantities if the positive direction of any branch be determined according to the definition already given. Otherwise a direction in each branch must be chosen arbitrarily as the positive direction, and the resistance function R_{xy} must be defined according to equation (13) or equation (15), where A and B are the positive ends and C and D the negative ends of the two branches respectively. In this case Maxwell's investigation shows that a positive electromotive force E_x in the branch x will produce a current E_x/R_{xy} in the positive direction of the branch y. With this convention we can generalise equation (5); for if w be any branch of the network, and if x, y, z be any three branches meeting in a point, we have

$$\frac{1}{R_{wx}}+\frac{1}{R_{wy}}+\frac{1}{R_{wz}}=0 \quad . \quad . \quad . \quad . \quad . \quad (18)$$

where the branches are supposed to have their positive ends at the point. If one of the branches has its negative end at the point the sign of the corresponding network function must be changed. This equation but expresses the fact that the accumulation of electricity at the point is zero.

(To be continued.)

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis:—

RECHERCHES SUR LA CONDUCTIBILITE GALVANIQUE DES ELECTROLYTES.*

BY SVANTÉ ARRHENIUS.

FIRST PART.

ON THE CONDUCTIVITY OF EXTREMELY DILUTE AQUEOUS SOLUTIONS DETERMINED BY MEANS OF THE DEPOLARISER.

Critical Analysis by OLIVER LODGE.

Whatever may have been the importance of the *First Part* of this memoir at the date of its appearance (1883), the publication last October in Wiedemann's *Annalen* of a masterly memoir by Prof. F. Kohlrausch on the same subject throws it into the shade; for there can be no doubt that while the ground covered by both is similar, the Kohlrausch memoir is greatly superior, both in the experiments made and in the discussion upon them.

A brief abstract of this portion of Dr. Arrhenius's paper is all therefore that is now necessary; and if my criticisms on parts of it appear in any case caustic, I must express my regret to the author for the adverse opinion, and trust that my appreciation of a great deal in the Second Part will compensate for it to some extent. It seems to me that the author allows himself occasionally to indulge in an exploded type of reasoning, wherein, by manipulation of imaginary data, a confusion is produced, out of which emerge several laws more or less in agreement with experience, which are thenceforth labelled and referred to as theoretical deductions. I proceed to give an account of the contents.

§§ 1-8 are devoted to an account of the experimental method employed, and to a justification of it.

The method consists in the use of a differential galvanometer, one of whose branches consists of ordinary wire, while the other contains a current alternator in the shape of a wheel turned by hand, with alternate bars on its periphery rubbed by two springs (Edlund's "depolariser"). The alternating current from this instrument is led to a switch, which is able at pleasure to throw into circuit either the experimental tube of liquid or a wire resistance box.

A battery is arranged so that its current divides fairly equally between the two branches of the galvanometer; and one portion of the current, after being rendered alternating by the above arrangement, is diverted by the switch either to the electrolyte or to the adjustable resistance box. The resistances of the liquid and of the box are considered equal when the deflection of the galvanometer is independent of the position of the switch.

I must confess to surprise that this can be a satisfactory mode of measuring resistance: self-induction and electro-chemical capacity being so mixed up in it. Apparently, however, results fairly comparable with each other can be obtained.

§ 9. *Calculation from the Experimental Data.*—First, the conductivity of the original water used as solvent is subtracted from that of the solution, and the result claimed to be the conductivity of the salt alone. For this rule, as an empirical process justified *a posteriori*, there may be something (not much) to be said. But as a corollary from a "law" subsequently proved in this paper it is worthless. Possibly not much harm is done by using this rule in the special cases considered; at any rate, Kohlrausch does the same thing, but it is well to notice that the rule $k=k_1+k_2$, for conductivity of soluble salt and solvent respectively, assumes two things:

1st. That the law of divided circuit must hold when two conductors are intermingled; which is untrue.

2nd. That the conductivity of water itself remains unaffected by the presence of a foreign body; which is improbable.

Effect of Dilution.—A great part of the paper is taken up with the effect on conductivity which dilution with an equal quantity of water causes to solutions of various salts. This mode of expression is a roundabout sub-

* Mémoire présenté à l'Acad. des Sciences de Suède le 6 Juin, 1883. Published at Stockholm, Konigl. Boktryckeriet. Norstedt and Söner.

Digitized by Google

stitute for a straightforward expression by curve or formula for the relation between conductivity and concentration such as Kohlrausch attempts to give. However, as Dr. Arrhenius evidently prefers this mode of expression, and thinks a good deal of it, I translate his introduction of it (page 25 of his memoir).

"Table A shows that when a saline solution is diluted in a certain ratio [1 : 6·08, for instance] its conductivity diminishes in a certain other ratio [not in general a very different one]. To render these numbers comparable among themselves in the different series a recalculation has been made, in which all dilutions are reduced to the ratio 1 : 2.

"This calculation is made in the following manner. If $1 : u$ is the proportion between the dilutions of two solutions of the same salt examined consecutively (*i.e.*, if one of the solutions is at times as dilute as the other), the proportion between the resistances in the two cases is, say, $1 : n$ (the value of n being taken from the table); that is to say, one of the solutions has a conductivity n times less than that of the other.

"If now $1 : x$ is the proportion between the resistances of two solutions when the dilutions are in the proportion 1 : 2, the following relation will hold good. If the dilution is $1 : 2^{\nu}$, the ratio of resistance (if the process is effected in a uniform manner) ought to be $1 : x^{\nu}$. In consequence we have $1 : 2^{\nu} = 1 : u$, and $1 : x^{\nu} = 1 : n$, which enables x to be calculated by the following formula :—

$$\log\log x = \log\log n - \log\log u + \log\log 2.$$

"The values of x calculated from this formula, which, according to what has just been said, signifies the proportion in which the conductivity of one salt solution diminishes when it is diluted with water to double its volume, are laid down in Table B. This quantity we name the *exponent of dilution.*"

B is a long table wherein, after all, x does not turn out a constant—though it is roughly so, several values of x being given for each substance according to its degree of dilution. The values of x for all the substances range from 1·7 to 2·3, and their average value would seem to be about 1·95.

The introduction to the above formula for calculating x loses all meaning unless x is intended to be constant; but in so far as x is intended to be constant, the gist of the introduction may be paraphrased thus :—

The first approximation to the relation between k and m (conductivity and concentration) is that made by Kohlrausch, viz., that the two are proportional. This is roughly true for very dilute salt (not acid) solutions, but it breaks down in a manner shown by Kohlrausch's experimental curves for more concentrated ones, so that he suggests the formula—

$$k/m = A - A\,m^{\frac{1}{3}}$$

as a still closer, though still rough, approximation.

Arrhenius, however, prefers to assume that k is nearly proportional to m^r, where r is an index to be determined by experiment. This is fair enough as an hypothesis, and should have been set forth clearly, and then negatived by the result of his experiments in so far as they are dependable; the result, namely, that r varies from ·946 to 1·046; or, as a clumsier and bulkier proceeding, the value of r might be tabulated for every substance at various strengths. Instead, however, of calculating r, Arrhenius calculates 2^r, a number of no particular convenience; this he calls x, and tabulates. This number x, his *exponent of dilution*, he calculates from the equation—

$$\frac{\log x}{\log 2} = \frac{\log k/k^1}{\log m/m^1} = \frac{\log n}{\log u} \left[= r \right].$$

The power of confusion is very great, and I must confess that it has cost me a good deal of trouble to disentangle the real meaning of this said dilution exponent, and of the ideas involved in it.

I ought here to say that in 1884 M. Bouty independently expresses his results in terms of this same number, which he calls the ratio λ, showing that it has some experimental convenience. Bouty, however, does give absolute concentrations, and he *really* doubles the dilution each time. Arrhenius gives no absolute concentration; he dilutes largely, and then calculates what would have happened if he had only doubled the dilution by means of a formula which, after all, is not really correct. It is this, and still more the setting up the number as deduced from theoretical grounds, which one feels bound to condemn. Perhaps the idea in not giving absolute concentrations is that it is impossible accurately to tell them unless absolutely pure water were available to start with. But the difficulty of impure water tells just at much at every dilution, for it is a medley of things you are really adding. A great part of the merit of Kohlrausch's recent memoir is that he takes such immense pains over the quality of his water.

§ 10. List of bodies examined.

§ 11. Table A, giving resistance and temperature of different strengths of solution of the various substances, but no absolute strengths are given; *ratios* of dilution are all that are specified. The columns, in fact, show $1/n$ and $1/u$.

Table B contains the "exponents of dilution," x, calculated for the different substances; it tends to show a slow increase in x as the solution becomes weaker.

Table B′ contains similar numbers, calculated from some experimental results of Lenz for stronger solutions.

The net result of these tables is that they help to confirm the later results of Kohlrausch. For all salts other than hydrates the value of x becomes practically equal to 2 as the solutions become very weak (*i.e.*, r becomes unity), and this means simply that k/m for such solutions is approximately a constant.

For stronger solution x diminishes, and this means simply that k/m fal's off, just as Kohlrausch's curves more instructively show.

§§ 12 and 13. *Discussion of the Tables.*

§ 14. *Influence of Temperature on Conductivity.*—Dilution and heating exert a similar influence on molecular conductivity.

Chapter III.—Theory.

§ 15. *On Conductivity considered as a Function of Concentration.*—Kohlrausch and most authors suppose that k/m is constant for extreme dilution; "nevertheless he seems to make the statement with a certain reserve, for in another passage he says, 'This number [gramme-molecules per c c.] can, according to all the experiments, be put proportional to the conductivity of attenuated solutions, provided *extreme* attenuation be excepted.' Nevertheless it is not difficult to prove that such a proportionality follows from the principles postulated in his work, and that precisely for solutions of extreme attenuation."

Then follows a proof from Kohlrausch's surmises, and from Hittorf's hypotheses—

(1) *That k/m is necessarily constant;*
(2) *That when two or more salts are dissolved the conductivity of the whole is the sum of the separate conductivities;* and
(3) *That the conductivity of a solution equals the sum of conductivity of salt and solvent.*

To all this it is necessary and sufficient to remark that the surmises of a philosopher, which are, to some extent, upset by his own experimental results, and accordingly by him stated "with a certain reserve," afford a very insecure basis for an elaborate proof, and for deductions therefrom.

If it be once granted—1st, that the conductivity of the water in solution is, under all circumstances, *nil*, or extremely small; 2nd, that every atom of a salt added conducts equally, and independently of every other—the laws stated are pretty obvious without further proof. But it is of little use attempting to prove these laws by begging the question.

§ 16 contains statements numbered (4) and (5), viz., *If the three laws are not true, it must be because of chemical action between the substances.*

§ 17. Hydrates (*i.e.*, hydrogen compounds, like acids and bases) are peculiar; either because they dissolve glass or because impurities contained in distilled water act upon them chemically, and alter them.

§ 18. Statement No. 6.—*The "exponent of dilution" is less than 2 for salts, greater than 2 for hydrates.*

§ 19. *Exceptions.*

§ 20. *Nature of the Resistance of Electrolytes.*—A hypothetical discussion of the friction between atoms, the mode in which ions rub against other molecules, and of the amount of rotation they produce in them, with three conclusions, numbered respectively—

(7) *The resistance of a solution is greater as the internal friction is greater.*
(8) *The resistance is greater as the ions are more complex.*
(9) *The resistance is greater as the molecular weight of the solvent is greater.*

§ 21. *Properties of Solutions of Normal Salts.*—Discussion of some results of Hittorf, and four statements—

(10) *Salts which are able to form double salts are most liable to have complex molecules.*
(11) *Aqueous solutions contain the electrolyte dissolved, at least partially, in the form of molecular complexes.*
(12) *Dilution diminishes complexity towards an asymptotic limit.*
(13) *The limit towards which the complexity of a dissolved normal salt approaches at extreme attenuation is the same for all normal salts.*

I feel that this brief analysis is not quite fair to the contents of these last sections, which are ingenious and interesting; but I scarcely think a detailed discussion of them would repay perusal, inasmuch as the author allows himself rather too freely the use of hypothesis concerning wholly unknown molecular interactions. Perhaps it will be fairer if I give the *résumé* in full.

Résumé.

"In the first six sections of the present work we have described a new method of measuring the resistance of electrolytic conductors. In this method we made use of rapidly alternating currents, produced by a depolariser constructed for the purpose by M. Edlund. We have tried to show the use of this method, and to make clear the practical advantages which it possesses.

"In the next part we have treated the process of making the observations, and of calculating the results. Then we have displayed the figures found for very dilute solutions of forty-five different bodies. Finally, we have discussed preliminarily the figures obtained, with regard to the exponent of dilution, the molecular conductivity, and the temperature coefficient.

"In Chapter III. we have, guided by the data of MM. Kohlrausch and Hittorf, laid down the proposition of the proportionality between the conductivity and the number of electrolytic molecules of a dilute solution, as well as two other propositions, according to which the figures of the previous part were calculated (1) (2) (3). Moreover, we have shown that if these propositions are not applicable, it is necessary to suppose that, with dilution of electrolytic solutions, chemical reactions are set up (4) (5). Proceeding from these different propositions, we have shown that all salts, properly so called, in solution are composed of complex molecules, which are partly destroyed by dilution. We have also indicated the manner in which these complexes are formed.

"By aid of this conception the properties of salts at all dilutions have been explained, as well as the properties of all electrolytes at considerable concentration.

"On the other hand hydrates,* and salts which partially transform themselves into hydrates, manifest other properties when much diluted. We

* By hydrates the author always means hydrogen compounds like acids and bases; and the salts next spoken of are the so called "acid" salts.

Digitized by Google

have shown that this singularity can be explained by the action of impurities which accompany the water used to dissolve them.

"By some considerations as to the nature of galvanic resistance we have been brought to the conclusions numbered (7), (8), and (9), of which the two latter complete the first, which indicate the long known relation between galvanic resistance and internal friction. The two propositions (8) and (9) are also in agreement with published data."

(*To be continued.*)

LEGAL INTELLIGENCE.

The United Telephone Company v. The Lancashire and Cheshire Telephone Exchange Company.

In the Queen's Bench Division, before Mr. Baron Pollock, on Wednesday, an action was brought by the United Telephone Company against the Lancashire and Cheshire Telephone Exchange Company.

Mr. Finlay, Q.C., Mr. Moulton, Q.C., and Mr. Bremner were for the plaintiffs; and Mr. Aspland, Q.C., and Mr. Lush Wilson for the defendants.

The litigation arose out of two agreements. The first was dated May 25, 1881, and it said that the defendants should in their district have the use of the plaintiffs' receivers and transmitters, paying for each instrument annually a rent or royalty of £1. The date of payment was to be January 1 in each year, and it was to be for the whole preceding twelve months, and a proportionate amount for any part of that period. It was found that this hard and fast system of payment was too inelastic, some telephones being very much more valuable to the defendants than others were, and therefore a new agreement was come to. This was dated June 23, 1885, and it substituted for the previous mode of payment that the plaintiffs were to receive from the defendants 12½ or 10 per cent. upon the gross receipts of the defendants for exchange work, and this agreement was to be in operation from January 1, 1885. It was said that the defendants were in the habit of receiving from their customers annual payments in advance. These arrangements were, of course, entered into at all periods of the year, so that some of those which were made in 1884 would have the best part of their term to run in 1885. The principal questions in dispute were under which agreement and how the payments were to be made to the plaintiffs in respect of those arrangements made by the defendants the payments for which were made in one year, but which were to continue into the following year. The plaintiffs claimed that there was due to them £7,786 and interest.

Considerable correspondence was laid before the Court, and a long argument was addressed to his lordship.

Baron POLLOCK, in the end, said that the case was not entirely free from difficulty, but he thought that all the accounts up to the end of 1884 should be settled on the basis of the old agreement; and any money earned subsequently should be paid for under the agreement of June, 1885. According to an arrangement made it would be referred to an accountant to settle what, upon this basis, was due to the plaintiffs, and there would be judgment for the plaintiffs for that amount, with interest at 5 per cent.

Judgment was accordingly given for the plaintiff.

COMPANIES' MEETINGS.

Eastern Telegraph Company (Limited).

The thirtieth half-yearly general meeting of this Company was held on the 14th inst., at Winchester House, Old Broad-street, under the presidency of John Pender, Esq.

The SECRETARY (Mr. George Draper) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN stated that the revenue for the last six months ended March 31st last had been £331,862, being a decrease of £9,543 compared with that of the corresponding period of 1886. The balance brought forward from the last half year's accounts was £19,458 less than in 1886. They now had to deal with the sum of £28,902 less than at that time last year. The total working expenses for the half year had been £33,035, or a decrease of £9,209. That arose in a measure from the absence of extraordinary expenses, which were unavoidable in time of war. The general expenses in London had been £8,169, being a decrease of £604. The working expenses at stations had been £60,674, against £64,439. The expenses attending repairs and renewals of cables had been £43,903, being an increase of £2,266. One of the items in that account was for the completion of the repairs to the Direct Lisbon cable, which had now been almost entirely renewed. One of the company's ships, the screw steamer "John Pender," had been fitted up with new boilers and improved electric light, and thoroughly overhauled and re-classed at Lloyd's. The expenses of carrying out that work, together with the extensive alterations and improvements which were made to the hull, and picking up the gear, &c., of the screw steamer "Volta," had been charged to maintenance ships' fund. They had laid in about 135 miles of new cable during the six months. Notwithstanding the reduction in revenue to which he had referred, it was satisfactory to find that after charging all expenses, including income-tax, providing for interest on debentures, debenture stock and preference shares, they were still able to pay a dividend and bonus on the ordinary shares at the rate of 5½ per cent. for the year, and to carry forward £48,000 to the general reserve fund. When he had the pleasure of addressing them last January he told them that they had been paying a bonus for some two or three years, but he then stated that the reductions which were forced upon them at Berlin took away something like £40,000, and that that practically did away with their bonus. He thought that on the same occasion he shadowed forth the probability—believing as he did in the recuperative power of the telegraphic system—that a year would not pass away without at any rate their being able to pay some portion of, if not all, the bonus. Strange to say, during the first few months of the reduction in the rates there had been a decrease rather than an increase in their traffic. That, however, was temporary, and he was glad to say that in the last two or three months there had been an increase, and they were now enabled to pay for the six months a bonus of ½ per cent. He hoped that would be satisfactory to the body of the shareholders. Since he last addressed them they had connected Tangiers with their cable system in Gibraltar. They found that there was a great want of telegraphic communication, and they were requested to do this work, which he was glad to say, had met a great public want. The cable was working satisfactorily, and the return had been much in advance of what had been anticipated. That would be another feeder to their system. The Italian Government had also, under the Company's more immediate eye, laid a telegraph connecting Massowah and Assab with the Company's station at Perim. That would be an additional feeder to their system. The Company undertook to protect that cable for three months, for which they received £5,000; and that was very satisfactory, seeing that no work had been required from them for it. There was another important question which he shadowed forth at the last meeting. He then said that to make themselves thoroughly independent it might be necessary to lay another cable from the Land's End to Gibraltar and Malta, to make them entirely independent of their cable system through France. Looking at the state of affairs on the Continent, probably they had not undertaken to do that work one day too soon. Anyone reading *The Times* of that day must be struck with the critical position in which Europe was at the present moment. It had always been the policy of the Directors to be ahead of requirements in their work. They believed they had the support of the shareholders in thus acting, as long as they saw their way to maintain their dividend. In carrying out this work they would saddle the Company with a very small amount of capital, and it would give them independence in maintaining their dividend. They had had a line through France for some years, which they had occupied very considerably, but they had felt that it was not a safe line to rely upon, and difficulties were being thrown in their way by the French Government to their renewing the concession. They had before anticipated the wants of the Government, and they believed that they were now anticipating the requirements of the Government and of the nation, and that in doing so they were adding to the stability and position of the Company. That cable could be laid and working within the next two months, and it could be laid sooner if desired. They had intimated to the Government the amount they would have to pay if at any time they required a preferential working of that cable. He believed that what they had done would commend itself to the Government, as he was pleased to find it had commended itself to the shareholders. During the last six months they had lost another steamer, the "Volta," but they could not understand how it had occurred except on the plea that the captain and officers of the ship had become so accustomed to sailing among the islands of the Greek Archipelago that they had got to believe that the ship could take care of itself. The Board of Trade had made a very careful inquiry, and had relieved the Company from all blame, reporting that the vessel had been kept in a most efficient condition. The misfortune had been attended with no pecuniary loss to the Company. The insurance money would pay for the ship they were now building to replace the "Volta." Their 5 per cent. debentures were terminable on the 1st of August, and they had decided to issue 4 per cent. mortgage debenture stock to replace them. The stock was being taken up pretty freely by those who had the 5 per cent. debentures. The change would effect a certain saving to the Company, and he thought it showed the solid position in which the Company was viewed by the investing public. In the earlier stages of the Company he had said that the property was a property the importance and value of which they had yet to learn. Every year had taught them that they controlled and commanded it. If a fault occurred to-day, they could say within a few days, almost to a certainty, that the fault would be repaired. Therefore, they had established what might be called a permanent property, and in that light it was being viewed by those who were taking up the 4 per cent. debenture stock. It was during the last twenty years that submarine telegraphy had been established and brought to its present position, and probably nothing had been done during the 50 years' reign of Her Majesty that had left a greater mark upon human progress than the submarine system of telegraphy. The subject of federation had been much talked about. He maintained that the submarine telegraph system had been the means of bringing about a great moral confederation. It had brought our colonies and the mother country into daily, almost hourly, communication. He thought they might congratulate themselves as a company on the great work they had done. He trusted that that work would continue, that the telegraph would play an important part in preventing war, and that if war did occur it would play a still more important work in bringing it to a close. He concluded by moving the adoption of the report, and the declaration of the dividend and bonus recommended.

Mr. G. G. NICOL seconded the motion.

In answer to questions,

The CHAIRMAN said that the existing 5 per cent. debentures were a terminable security, while the 4 per cent. mortgage debenture stock would be a permanent security, and have a first charge on the Company's undertaking. When they established the bonus principle it was pointed out that the amount would be of a fluctuating character, and they agreed to consider 5 per cent. as the dividend. He hoped next half year that

Digitized by Google

they might again pay the ½ per cent bonus. In keeping ahead of the wants of the Government and of the country they had received very great and important consideration from the Government For instance, they had the exclusive right for a great many years of landing cables in Egypt. If they were to stand still they would go back, and, in fact, they must meet the demand on them as far as possible and be ahead of it. In answer to Mr. Husband, he stated how they proposed to pay for the new cable, pointing out that the capital would be saddled with only £75,000. By the arrangements contemplated in connection with the new cable they hoped to save £21,000 a year, which they would practically get towards the payment of the interest on the new capital. He looked forward to a very large increase in their traffic. In reply to Mr. Fowler's question they were going to raise the money for the new cable in such a way as to add but little to the capital. The present arrangement with France would continue till next year; but that country might be in a blaze to-morrow. Their ship was at Porthcurrow, with a large amount of the cable on board for the new line. Some day they would have an alternative line from Bilbao to Barcelona connecting with their system, and from Barcelona they would connect with their own system at Gibraltar at a very small expense. That would give them another line.

The motion was then unanimously adopted.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

[We shall publish a full report of this meeting in our next issue.]

South of England Telephone Company (Limited).

An adjourned meeting of this Company was held at Winchester House, 50, Old Broad-street, E.C., on Tuesday, the 12th inst., Mr. David Owen Bateson presiding.

The SECRETARY (Mr. F. L. Robinson) having read the notice convening the meeting,

Mr. HENRY ROBERTS proposed, "That the sum of £200 be paid to the Directors for their services during the twelve months ending 30th April, 1887."

Mr. A. MARSHALL seconded the resolution, which was carried unanimously.

Mr. A. MARSHALL proposed:—"That the election of the Chairman as Managing Director, made by the Board, 28th October, 1886, with a salary at the rate of £500 per annum, from the 18th March, 1886, be and is hereby confirmed." The speaker made flattering reference to the able manner in which Mr. Bateson had carried on the affairs of the Company.

Mr. JOHN TAYLOR, in seconding the motion, said that if the business of the Company was conducted in the future as it had been in the past, the time was not far distant when the shareholders would find themselves in a very prosperous position, a fact which he was sure they would substantially recognise as largely due to the labours of the Chairman.

Dr. ELLIS (Eastbourne) said that, as a general rule, he did not think the Managing Director and Chairman of the Company should be one and the same person, but in the present case he had no hesitation in supporting the motion.

The resolution was agreed to *nem. con*

In answer to Mr. W. P. Ponsford, the auditor (Mr. J. Weiss) promised to give a more detailed statement of accounts next year.

Dr. ELLIS proposed, and Mr. JOHN TAYLOR seconded, the re election of Mr. Bateson, the retiring Director, which was unanimously agreed to.

The CHAIRMAN having briefly expressed his thanks,

The auditor was reappointed, and a vote of thanks passed to the Chairman, which concluded the business.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 8th inst. amounted to £3,762.

CUBA SUBMARINE TELEGRAPH COMPANY.—At a meeting of the Board of Directors of this Company, held on Wednesday, the audited accounts for the half-year to June 30 were submitted, and it was resolved, after providing for the distribution on the preference shares, and placing £4,500 to the reserve fund, to recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax. The sum to be carried forward is £840.
